Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

NEW YORK'S ELECTRICAL SUBWAYS.—I.

BY

Wm Maver Jr.

I.—INTRODUCTORY.

WHEN, in February 1890, I was preparing the paper which I had the honor of reading before the American Institute of Electrical Engineers, on "The Practical Working of the Electrical Subways of New York City"[1], I was well aware that the general opinion of the electrical public, more especially that portion of it engaged in the business of electric lighting by high potential currents, was that no successful system of underground electrical subways, short of a tunnel, perhaps, could be devised. I, therefore, took particular pains to state clearly the exact construction and condition of the subways in question and of the conductors within them; the difficulties which had been and which were to be overcome, and the results accomplished.

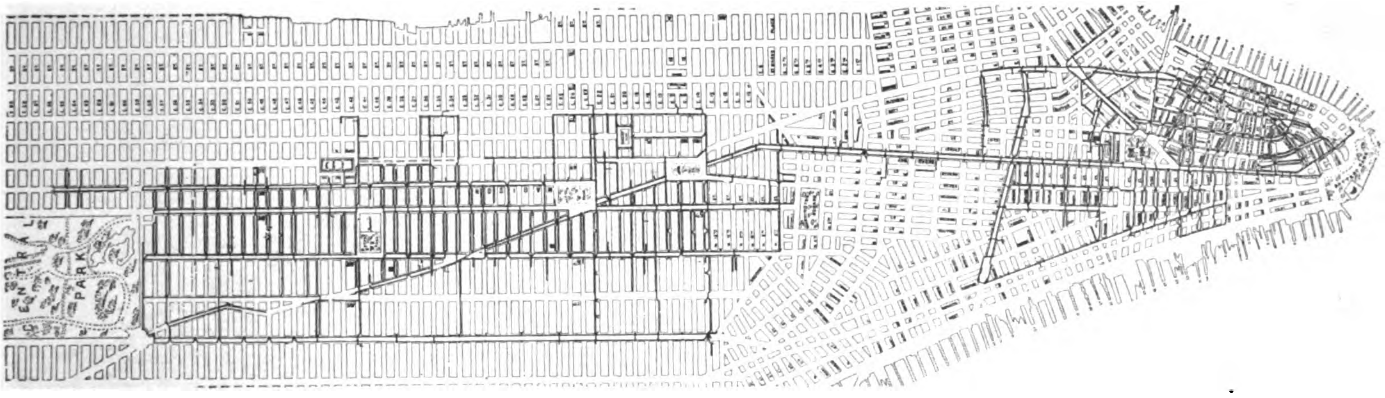

Fig. 2.—Map Showing the Location of the Edison Underground Circuits in New York City.

It is my purpose in this article to give a more detailed illustration and description of the route of the electrical subways of this city, than appeared in the paper mentioned, and of the route and character of the electric circuits, more particularly of the electric light circuits; the type, of cable used; the "distribution" methods employed; the question of gas in the subways, etc.; together with various items of possible interest connected with the practical operation, electrically and mechanically considered, of the subways, during the past five years.

It is generally known that the, so-called, high potential electric light subways and those assigned to telephone and telegraph circuits are of the "drawing in and out" type, and that the "Edison" conduits are of the solid, or permanent, type. The former admits of drawing cables into or out of the ducts, or of drawing in additional cables up to the capacity of the duct, as desired. The latter, on the contrary, does not. A conductor when once placed in position remains until it may be lifted bodily out of its trench. It is obvious that where flexibility is required and especially where many different companies are to be provided with facilities, as in New York City, a "drawing in and out" method must be employed.

II.—ROUTES AND METHODS.

The routes of the "high potential" subways are shown in map, Fig. 1; those of the Edison conduits in map, Fig. 2; those of the telegraph and telephone in map, Fig. 3. The entire electrical subway system south of Worth street is shown in Fig. 4. With but few exceptions, the telegraph and telephone subways are placed on opposite sides of the streets to those of the high potential subways.

There are 70 miles of high potential subways in this city. Of the telegraph and telephone subways there are 45 miles. Of the Edison conduits there are 160 miles. In all 275 miles.

The material of the various subways is mainly wrought iron; but cast iron, cement, creosoted wood, etc., are also employed, as more specifically mentioned in my Institute paper. The ducts range from two to four inches in diameter. There are in all 1,312 miles of ducts in these subways, exclusive of the "Edison" conduits, of which there are 160 miles. The ducts are divided into two classes, termed, respectively, trunk and distributing ducts. These, as the names imply, are alloted to "through" and "way" circuits, respectively, further reference to which will shortly be made.

Access to the "drawing in and out" conduits is obtained by means of man-holes, placed at suitable distances apart, usually about 200 feet. These man-holes are of brick, laid in concrete cement. Entrance to the man-holes is made through a cast iron head, set on the brick-work, and which is provided with heavy double cast iron covers. The manholes average five feet in width and from five to ten feet in depth.

---

[1] See The Electrical Engineer, March, 1890.

Access to the Edison conductors is obtained by surface boxes placed at convenient distances apart. These boxes also have an inner and outer removable cover.

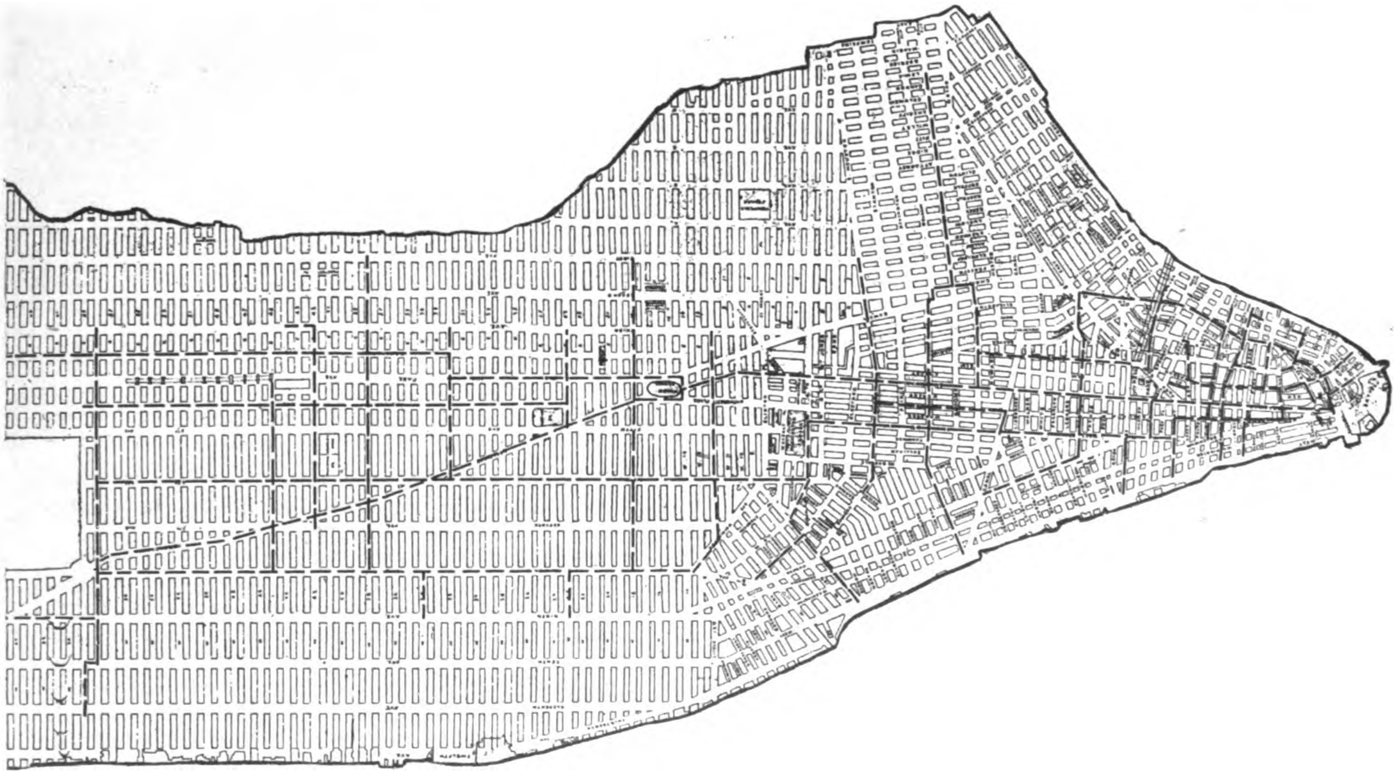

FIG. 3.—MAP SHOWING THE LOCATION OF THE UNDERGROUND TELEGRAPH AND TELEPHONE CIRCUITS IN NEW YORK CITY.

III.—WROUGHT IRON DUCTS.

In all the recent subway construction work done in New York, wrought iron pipe has been used, that material having been found to give the most generally satisfactory results as regards flexibility and strength. Thus far the iron pipes have not been found to introduce any marked electrical complications. Of course, it is essential, to avoid "throttling," to place both legs of alternating circuits in the same duct. Rough tests have indicated that losses due to self-induction, etc., are about three times greater when the conductors of such circuits are in separate ducts than when in the same duct. In the case of telephone circuits it is well known that the transmission is retarded by placing the conductors underground, due to the increased electrostatic capacity of the cables.

The wrought iron pipes are laid in hydraulic concrete and are covered by a row of two inch creosoted planking, to protect them from pick axes, crow bars, etc., in subsequent excavations of the streets. This covering has been found sufficient in almost every instance. On one occasion only has it failed, namely, when a contractor, in sinking an iron bar to serve as an "anchor" for a derrick, forced a way through one of the ducts. These wrought iron pipes are from 18 to 21 feet in length, about one quarter inch in thickness and weigh from 5½ to 8 lbs. per foot, depending on the diameter. The pipes, before leaving the works, are dipped in a preservative formed of a mixture of asphaltum and other ingredients, which is allowed to drain off, leaving only a thin coating inside and out. This mixture speedily dries and does not soften again under the ordinary temperatures met with in the subways, and thus the coating does not impede the drawing in or out of cables.

The pipes in the trench are connected together by coup-

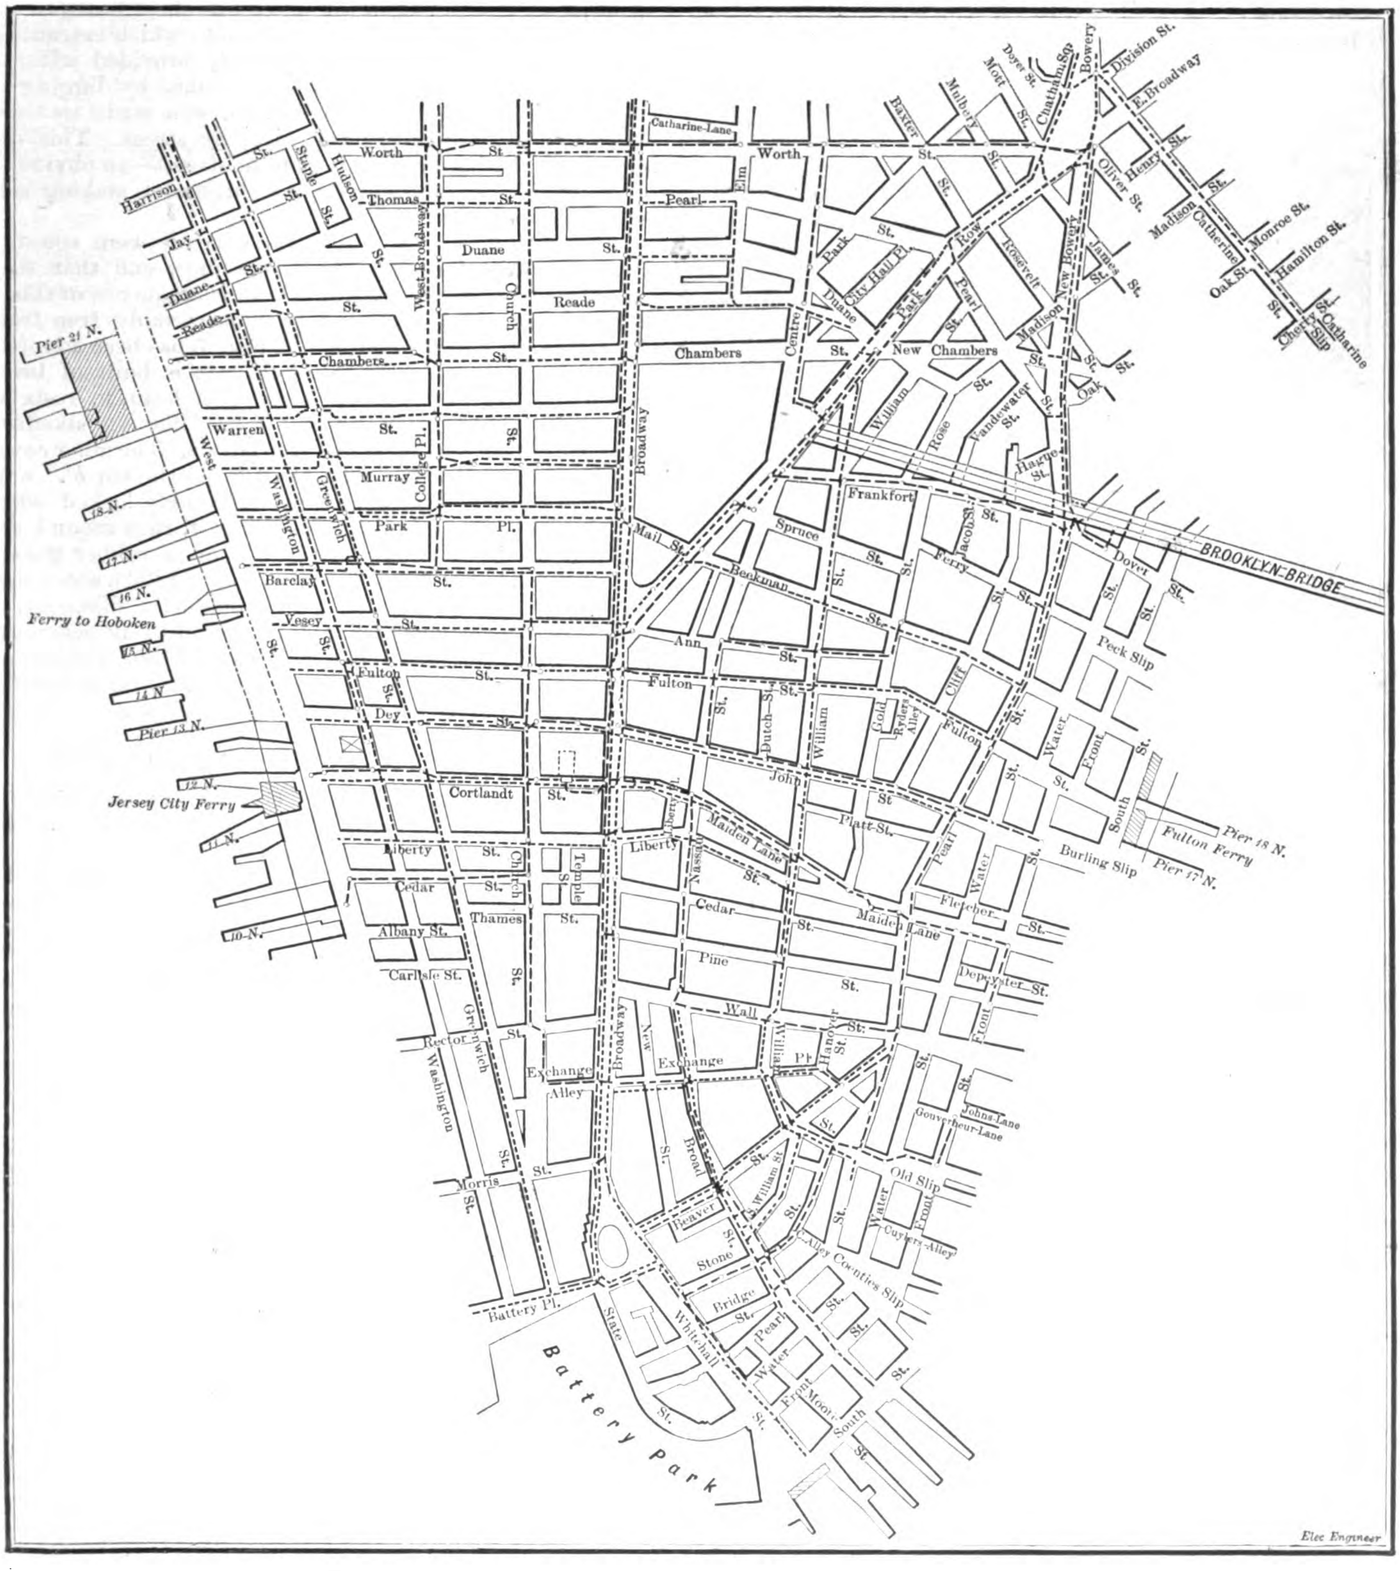

FIG. 4.—COMPLETE SUBWAY MAP, LOWER PART OF NEW YORK CITY.

lings having tapering or vanishing threads. The tapering threads are of great utility in facilitating the work of connecting up the pipes.

IV.—OBSTRUCTIONS IN THE DUCTS.

It is, of course, evident that great care must be taken, in constructing the subways, to remove any substances from the pipes which would be at all likely to act as an obstruction to rodding the ducts or to drawing in cables. In the hurry and the bustle that naturally attend the building of subways in the busiest streets of a large city, however, it is almost too much to expect that many miles of ducts could be laid without some obstructions being found in them afterwards. To minimize the difficulty it is customary to inspect each pipe before it is connected in its place.

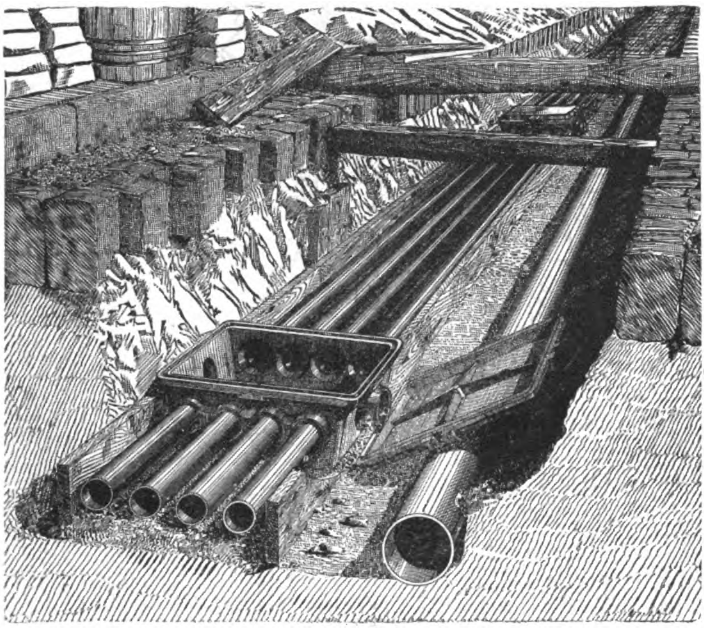

FIG. 5.—OLD FORM OF DISTRIBUTING BOX.

Some of the obstructions found in the New York subways have been of a rather curious nature. In one instance a mandrel was picked up; in another an umbrella, etc., Cement and stones, have, of course, been the most frequent causes of obstruction. In several instances the tools employed in the work of removing obstructions have had to be especially designed to meet the requirements of each case. On more than one occasion the nature or form of the obstruction has been ascertained by taking an impression of it on a suitable matrix pushed along the duct for the purpose.

V.—TRUNK AND DISTRIBUTING DUCTS.

The trunk, or "through," ducts are laid at the bottom of the trench and are not accessible between man-holes. There are no distributing ducts in the telegraph and telephone subways, distribution being made from the regular man-holes. In the case of the Fire Department circuits, the terminals of the cables are brought up to a box placed on the street lamp posts at desired intervals, thereby greatly facilitating necessary changes of circuits. Where lamp posts are not available, the terminals are led into a tubular box, about the size of an ordinary hydrant, on the curb of the street.

The distributing ducts of the electric light subways are placed as near the surface of the street as practicable; being generally from one and a half to two feet below the street level. Access to the distributing ducts between man-holes is now had by means of surface boxes placed at intervals of 50 feet along the route of the ducts. One of the boxes first used for this service, in connection with the wrought iron conduits, may be seen in Fig. 5. It is an iron box about 1.5 foot long and one foot deep. On its end and sides, holes, or spigots, are arranged. The distributing ducts run into the end holes. When it is required to make a connection with a cable in a distributing duct, what is termed a "subsidiary" is laid from the nearest of these boxes to the lamp post or basement of a building into which entrance is desired. These boxes were originally provided with an iron cover, and access to them was obtained by digging up the street. Subsequently, an addition was made to these boxes which raised them flush with the street. This did away with the need of digging up the streets—an obviously objectionable proceeding—for the purpose of making side connections with the cables.

It was found, however, that these boxes were speedily filled with deposits from street washings, and that they settled more than was desirable. In consequence of this a form of surface distributing box, measurably free from these defects, shown in outline in Fig. 6, has been adopted. It is virtually a miniature man-hole. It is built of brick on a foundation of cement. A cast iron head, H, rests as indicated, on the brick walls. It has, like the standard man-hole, outer and inner cast iron covers. The inner cover *c* is held down by the screw bolt *b* and the bar *b*¹. *c*¹ is the outer cover. The inner cover is securely locked when the box is not in use. A curved flange *f*, runs around the cast iron head. The inner cover lies on a rubber gasket resting on this flange. To carry off any surface water that may obtain entrance, a pipe P, two inches in diameter, is dropped from the curved flange to a blind drain below the foundation of the box. This box is about two feet square. The distributing and subsidiary ducts are arranged virtually as described in the case of the original box.

VI.—CAPACITY OF THE SUBWAYS; CIRCUITS, ETC.

The subways in New York City have a capacity for 45,000 miles of telephone and telegraph conductors, and for 5,000 miles of high potential electric light circuits approximately. There are at present about 23,000 miles of telephone and telegraph conductors in the ducts. There are 600 miles of high potential cables employed in the operation of 132 electric light and power circuits. Of these, 88 are continuous current and 44 are alternating current circuits. The conductors of these circuits carry current for, approximately, 3,300 arc lamps and for 80,000 incandescent lamps. The length of these circuits varies from 1 to 14 miles. It may be noted that the tendency is towards longer circuits. On this account, while there are at present more miles of electric light cables than there were one year ago, there are fewer circuits. The maximum electromotive force employed in the arc light circuits is about 3,500 volts. There does not seem much

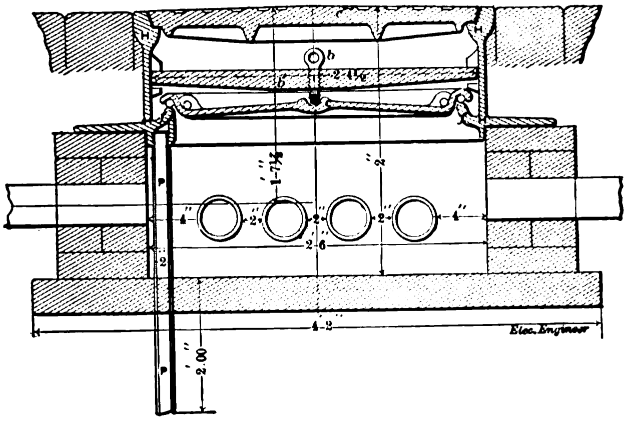

FIG. 6.—NEW FORM OF DISTRIBUTING BOX.

reason to doubt that the majority of the electric light cables in the subways could withstand a pressure of at least 6,000 volts, continuous current.

The ducts of the New York subways are occupied by six different electric light companies, and six different telegraph and telephone companies. In several instances all of these companies occupy ducts on the same section of a given street. No specific districts of the city have been allotted to any given electric light company. Access to the subways to any given company is obtained by mutual arrangement or otherwise; the ducts having been assigned as called for. Tenants obtain access to the subways upon application to the Subway Inspectors who hold the keys of the manholes and surface boxes.

LAMINATED OR DIVIDED IRON AND OTHER METALLIC MASSES IN ELECTROMAGNETIC APPARATUS.—I.

BY

Thos D Lockwood

Dr. James Prescott Joule.

Every one who is familiar with electromagnetic or induction apparatus of nearly any kind, must have observed the wellnigh universal practice of dividing in some way the iron and sometimes other massive portions of such apparatus. We may state this proposition more broadly, by saying, "the iron, and in many instances the other metal portions of such apparatus, exclusive of course of the wire coils." We need not at present discuss the why and wherefore of the practice, but will content ourselves with calling to mind several familiar instances.

Consider the well-known "shocking" induction coil of the street electrician, and recall the fact that its core is made up of fine iron wires; and then further call to mind that the violence of the shock is modulated by a brass tube which is pushed in over the core or pulled out from the core, to weaken or strengthen the shocking currents to be administered to the victim and customer. In this case, note that the core is divided into wires, while the brass tube is not even divided by a slit; why? Because in the core we desire to prevent parasitic currents, while in the tube we desire to employ such currents. Many electromagnets also, we observe, have their cores halved or quartered, at least for a part of their length.

We have doubtless seen electromagnet coils wound on sheet-metal spools of iron, copper, or brass, and these have worked satisfactorily; but if we have in our early days tried to make such spools, and use them after we have made them, we have found that the power of the magnet was very small; and then later, too late often to be useful in that emergency, we have learned that there was a small but radical difference between the metal spools we *saw*, and those we *made*, in that the former were slit from end to end, while ours were not. We can remember also that in the early pictures of the Gramme ring, and the descriptions accompanying them, it appeared that the iron core thereof was composed of iron wire or rod; and that the core of the Brush machine armature was slitted and slotted into quite a number of fantastic configurations. And later, on the advent of the heavy current induction coil calling itself multifariously a secondary generator, a transformer, a converter, or even an exhorter, we know that laminated cores reached their apotheosis.

It seems therefore to have been accepted as a truth from far back times, that it is a good thing to divide the otherwise solid metal parts of electromagnetic appliances, and especially such metal parts as are made of iron. A closer observation of these divisions shows that the divisions are always made in a special direction with reference to the direction of the coil windings; and that direction is in a plane normal or perpendicular to the said winding.

Now, although, as I have said, makers and users seem to have concurred that the division of cores and other parts of apparatus is a good thing, yet it is likely enough, notwithstanding the luminous and voluminous record of what has been done in this connection, and why it has been done, that the number of those who could give an intelligent reason for lamination, and its direction, would be much smaller; and that the number of those who are acquainted with the genesis and evolution of the lamination is smaller yet. There is however no valid reason why all who read The Electrical Engineer should not know to whom this great feature in construction and operation should be attributed; and if, as often proves to be the case, it should turn out that the idea occurred to several persons at about the same time, then there is no reason why we should not weave our respect into a blanket mortgage, broad enough for all concerned. Aside from the meretricious advantage of the mere knowledge of to whom the honors of discovery are due, there is also, I conceive, great interest attaching to the story of the progress of any useful idea, especially when it concerns electrotechnics; and, finally, it is a good idea to have at our disposal a considerable amount of information on the same subject, all in one place, for ready reference.

The great reason for laminating or dividing cores and other metal portions of electromagnetic apparatus, is (to use a Stocktonism), the discouragement of eddy or parasitic currents. This is the principal reason, because it is the reason which applies both to iron and to other metals. Wherever changes in electric currents are occurring, or wherever changes in magnetism are occurring, there is also, of course, a tendency for the development of induced currents in any closed circuit which is sufficiently near, and in inductive relation to, such changes. In a dynamo, the core of the armature is in such relation to its coils. In an electromagnet, a metal spool surrounding the iron core and itself surrounded by the coils is in such relation. In an induction coil or transformer the core (cylindrical or otherwise), is in such relation to the coils.

Eddy currents, to exist at all, must have a closed circuit within which they may flow; and it is clear that they can readily find such a closed circuit in solid cores, shells, pole-pieces and similar masses of metal; and being developed in the said closed circuits they wastefully absorb power. If now we split, laminate, or divide these masses we break up the circuit within which the parasitical current flows, and thereby prevent, or greatly diminish, their development, and correspondingly reduce the waste. When the eddy current flows in the core or pole-piece of a dynamo machine or transformer, it not only reduces the output of useful current, but also develops heat; and when set up in a brass spool surrounding the pole of an electromagnet or analogous device, it opposes itself to the energizing effect of the legitimate current, and makes a weaker and more sluggish magnet. Therefore these eddy currents must be *discouraged*, except when, as in the regulating sleeve of an induction coil, we can make them useful; and lamination is our means for discouragement.

Now there is no difference in kind, between the fine wire division of the induction coil core, and the plate or true lamination division of the drum armature core. To state the proposition conversely, the difference between the built-up plate ring core of the Schuckert machine, or the laminated core of the modern transformer, and the finely divided wire core of the old-fashioned Page–Callan–Sturgeon–Ritchie–Ruhmkorff induction coil, is but one of degree. Both are finely divided iron, and both are finely divided for the same broad reason, namely, to prevent waste of energy.

Somebody, somewhere, has said that a Frenchman when asked to differentiate the several well defined and separate agonies of rheumatism and gout, did so by saying, "Put your finger in a vise and turn the screw until it hurts so that you cannot bear another turn; that is rheumatism. Then give one turn more, and that is gout." Just so; divide your core or your shell into thin plates, scales, or laminæ, pile these in layers one upon another, and you have a laminated core or shell. Then take the core so composed, set it up so that you see the flat side of the top plate, and cut the pile through again and again until you have sliced your plates into rods, and then you will have a fine wire core, or a core of finely divided iron, such as we have always been accustomed to associate with "shocking coils."

In preventing waste of energy by dividing iron cores or analogous masses, there is in addition to the discouragement of eddy currents, another element of waste to be looked out for. This element does not concern any other metal but iron. The molecular friction now known as hysteresis, opposes such swift magnetic change as is called for in the cores of generators and transformers. If swift magnetic change is forced upon a core, shell, or pole-piece, in spite of this opposition, heat is developed, and in this way also we have waste and loss. But the magnetic friction or opposition to change of a considerable mass of iron is much greater proportionately to the forces producing such change, than is that offered by an equal amount of iron when finely divided, and thus by laminating, we also diminish the heat and consequent loss attributable to hysteresis.

In generators of all kinds there is a third point of advantage in lamination. We must, of course, class under the head of generators not only the magneto or dynamo electric machine proper, but also the converter or secondary generator, the motor, and the choking coil, including all forms of retardation coils or electromagnetic resistances, inasmuch as these last owe their very existence to the fact that they develop counter E. M. F. The E. M. F. a generator develops, is, of course, dependent upon three factors, that is, the intensity of the field, the speed with which that field is traversed, and the amount of active conductor exposed to the action of the field. The second factor must include the speed with which the magnetism of a core or shell can be charged, discharged or reversed. Now small magnets can be charged, discharged, and reversely charged much quicker with a given force than can large ones. It takes a great deal more work to magnetize a solid mass of iron all through, to demagnetize it, and to magnetize it again with reversed poles, than it does to effectually magnetize and demagnetize an equal amount of iron when split up into thin plates and rods. The tendency of lamination here, is to save both time and work, and thus again there is an actual gain in result, in proportion to the expenditure of power. For, since magnetic change is facilitated, and made quicker and more perfect, the result is that the counter E. M. F. generated has a higher value; and the advantage is much more decided when the impressed changes of current, such as reversals, have a high frequency. These three factors then combine to produce the useful result of lamination or division.

The direction of division, as has already been stated, must, to accomplish the prevention or minimizing of eddy currents, be across the line of such currents; otherwise the circuit within which it flows will not be broken; and inasmuch as the parasitic current circulates round the core, as does also the exciting current in the insulated wire coils, it becomes obvious that the direction of division should be at right angles to the coils within which the exciting current circulates.

The component parts of the divided core or shell must also be in some way insulated from each other, as otherwise all that is accomplished by the division is to increase the resistance of the eddy current circuit. In some cases this insulation is brought about by applying an insulating coating to each lamination or wire; but in many cases, for example in the cores of the step-up induction coils, a layer of non-conducting oxide has been found sufficient.

ON THE EXACT ADJUSTMENT OF STANDARDS OF RESISTANCE AND THE DETERMINATIONS OF TEMPERATURE COEFFICIENTS.—II.

BY

Elmer G Willyoung

In the regular routine work of our laboratory we have been using thus far, for this work, a slide-wire bridge of the writer's design having three wires; only one of these wires is used as the bridge-wire proper and only this one is calibrated; one or both of the other two are thrown in multiple, as desired, with the first one, in order to reduce the effective resistance of the bridge. This does not, of course, change the calibration. This construction has fulfilled the second of the above specified essentials in a fairly satisfactory manner; good construction and design, of course, takes care of the first. In the bridge referred to, the wires were of the orthodox length of one meter. The 3d, 4th and 5th desiderata are, however, not so easy to fulfill in the ordinary pattern of bridge.

The result of my own experience in bridge work and of observation and inquiry into the methods of others has led me to conclude that any design of a Wheatstone bridge which is intended for exact work is fundamentally bad if it makes use of a straight wire of any length stretched between two points. I have several reasons for this belief. A bridge used in the average laboratory can not but be subjected to considerable variations of temperature from one time to another; sometimes this will not be over 5 or 10 degrees for an entire month at a time; again it may be 20 degrees in about as many hours. As the bases of most slide-wire bridges have been of wood having a coefficient of expansion considerably different from that of the german silver or platinum-iridium wires mounted upon them, it is evident that their temperature variations must produce, at times, considerable strain upon the soldered junctions of wire and end pieces when the wire has been tightly stretched, and it *must* be tightly stretched if good work is to be done. Probably the greatest strain, however, does not arise so much from the difference of expansion coefficients as from the change produced in the dimensions of the wooden support by reason of its absorbing or giving out moisture; for purposes of instrument construction it is practically impossible to find wood so well seasoned as not to deform in a very short time.

It is, consequently, not surprising that very few straight slide-wires ever remain in position very long. In fact I have never yet seen a straight wire bridge upon a wooden base, with wire stretched tightly enough to make an accurate measurement, whose wire would hold fast without pulling out within a week. The only remedy is to either place the wire upon a compensating base, or else to arrange the wire so that it may be slackened when not in use. In the "three-wire" bridge previously spoken of, the wires were fastened to sliding copper end plates which could be tightened and fastened to the end pieces proper by heavy copper connecting straps. But this having to tighten the wires is a nuisance, requires some strength, and is apt to mean slightly different settings and consequent lengths of wire at different times.

I have recently finished designs for a three-wire straight bridge from which the first instrument is now being made. Instead of a solid base the support for the wires will be a skeleton frame work of brass rods, the coefficient of expansion of which is not very far removed from that of the alloys which are usually used for bridge wires. A straight wire bridge has, however, still another defect, to my mind, fully as serious as the one mentioned. This is the tendency to the development of thermal currents, particularly where the wire is joined to the end coppers; the ends of the wire being a meter apart, it is entirely possible and indeed probable, that differences of temperature will exist in the air at the two ends of the wire, of sufficient amount to develop thermal electromotive forces of very appreciable values.

To make perfectly clear how important a consideration this is I must again refer to the theory of this "Carey-Foster" method. Let us assume that we are comparing two standard ohm coils together and that we wish to know one in terms of the other to an accuracy of $\frac{1}{200}$ per cent. that is, that we must have a deflection of the galvanometer needle when the slider is but $\frac{1}{20000}$ ohm from perfect balance. We will assume that we are using one cell of battery giving about one volt effective E. M. F. at the junction with the bridge arms. Since there are two ohms on each side the fall through $\frac{1}{20000}$ ohm is $\frac{1}{40000}$ of a volt. Let us also assume the bridge wire to be of german silver and the terminal ends to which the wire is fastened, copper. The thermal E. M. F. of this couple, assuming that the one end is at a temperature of 19 degrees and the other at 21 degrees C., a difference of but 2 degrees, is, according to Prof. Tait's table of thermoelectric heights

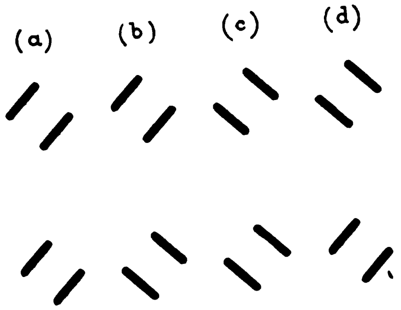

FIG. 5.

$$\begin{array}{lr} \text{German silver,} & -\ 1{,}207 - 5.12\ t \\ \text{Copper,} & +\ \ 136 + \ .95\ t \\ \hline & -\ 1{,}343 - 6.07\ t \end{array}$$

$$\text{E. M. F. per degree, } -1{,}343 - (6.07 \times 20) = 1{,}464 \text{ C. G. S.}$$

$$\text{E. M. F. of couple } 1{,}464 \times 2 = 2{,}928 \text{ C. G. S.} = \frac{3}{100{,}000} \text{ volt.}$$

This value just obtained is a trifle *greater* than the E. M. F. which must be detected by the galvanometer, and will, of course, throw our observations out by exactly the same amount and prevent our obtaining the required accuracy; if this happens when there is only *two* degrees difference between the ends and when but $\frac{1}{200}$ per cent. is aimed at, how will it be when there is four or five degrees difference, as there often is, and an accuracy of $\frac{1}{300}$ or $\frac{1}{400}$ per cent. to be attained and in addition innumerable other thermal E. M. F.'s due to other portions of the apparatus?

Of course there are other ways of eliminating the influence of thermal currents. The simplest is to use the galvanometer in place of the battery and to close the battery circuit upon the bridge wire. This plan is, however, not to be recommended. Another good way is to reverse the battery current, the thermal E. M. F. thus acting at one time *with* and at the other *against* the battery E. M. F.; the mean of the two is then the balance reading. This is easily accomplished in the apparatus which has been described by first taking readings with commutators turned parallel and then with commutators at right angles. For example, there would be four commutator positions necessary, as shown in Fig. 5. The difference of the mean of *a* and *b*, and the mean of *c* and *d* would represent the desired difference between x and s.

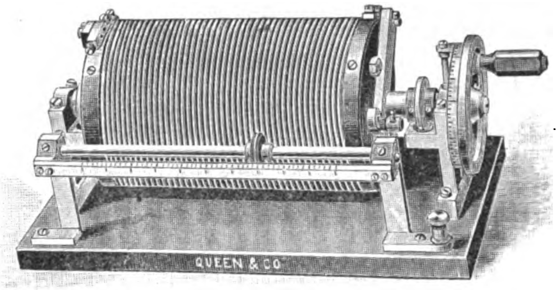

FIG 6.

The orthodox straight wire bridge, also, occupies considerable space and spreads out the apparatus necessary for the more common measurements in an undesirable manner, besides, in the case of regular Wheatstone bridge work, requiring one to get himself into all sorts of impossible positions in order to obtain and read his "balance." On account of all these reasons I personally favor a wire bridge having a wire bent one or more times about a circle or cylinder rather than the straight wire pattern.

A circular wire bridge, if well made, does all that the straight pattern will do and does it much more conveniently; it occupies but little space and brings the readings where they can be easily read; the ends of the wire are close together so that there is practically no difference in temperature between them, and the form is necessarily such that the wire cannot pull out of the end junctions. The contact also is usually a rolling, wheel contact giving a tangent point of contact and hence is not liable to injure the wire, as are most of the cutting "knife-edge" contacts on the usual forms of straight bridge. These conclusions as to the relative efficiency of straight and circularly laid wires in "slide wire" apparatus are not merely theoretical; they are practical, having been founded upon my own personal experience with both types in the making of very accurate measurements and upon the experience of those associated with me who are using the method every day in commercial work.

The form of wire bridge arrangement which I have finally been led to favor in preference to others is shown in Fig. 6 and, diagramatically in Fig. 7. The wire is here coiled upon a hard rubber cylinder 4 inches in diameter and 7 inches long; this cylinder is highly polished and the wire is stretched in a screw thread cut in its surface. There are 50 turns of wire upon the cylinder. In front of the

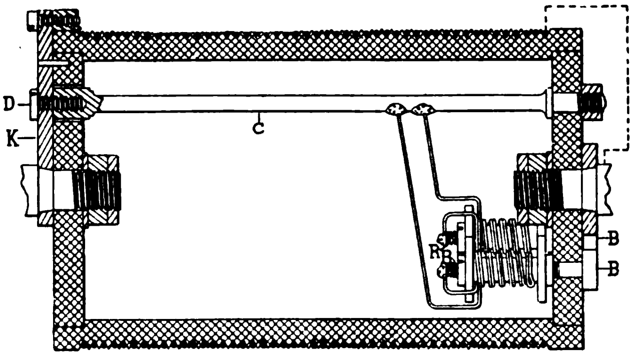

FIG 7.

cylinder is a scale, running the entire length of the cylinder, and, between the cylinder and scale, a small wheel sliding upon a bar carried by the same supports as the scale. This wheel bears snugly against the wire, the end supports being platinized and turned to as true a circle as possible so that the tangent contact is very sharp and definite. As the cylinder is caused to revolve upon its axis, by turning the handle at the end, the little contact wheel travels along the scale always in contact with the wire. The long scale indicates how many complete turns have been made.

In order to obtain the fraction of a turn, the wheel at the end is divided into 100 parts and each of these parts can be easily divided by the eye to tenths; this graduation is read by reference to a zero mark at its side, visible in the engraving. The bridge wire is thus divisible into 50 x 100 x 10 = 50,000 parts. In order, however, to measure accurately the extremely small resistances represented by the increase of resistance of, say, a platinum silver 1 ohm standard for 10 degrees C. increase of temperature, we must have a lower resistance bridge wire than could be obtained by bending any flexible wire upon a cylinder only 4 inches in diameter. The wire has, consequently, been shunted by two shunts placed inside the cylinder itself; these shunts are such that the total resistance of the bridge wire may be either 1 ohm or $\frac{1}{10}$ ohm, as desired, and are arranged so that either may be used by simply inserting a small plug at the end of the cylinder. If we use the $\frac{1}{10}$ ohm shunt the smallest difference measurable with the combined apparatus is $\frac{1}{50,000} \text{ x } \frac{1}{10}$ ohm = 0.000002 ohm; it is thus easy to measure, with great accuracy, an extremely small difference between two coils or to determine temperature coefficients even though extremely small.

The method of arranging the shunts in this apparatus is worthy of notice; they are so placed that their adjustment by the maker is easy and convenient. Referring to Fig. 7, the shunts are each mounted upon rods, B, screwing into the end blocks B; one end of each shunt is soldered to its rod. The other ends of each shunt are soldered to the rod C. In adjusting, the right hand head of the cylinder is slipped into position carrying with it the shunts and rod C; the shunts are adjusted as accurately as possible and the head slipped back. As the head slips into place, the rod C shoulders against a heavy copper strap K, connecting with the left hand end of the bridge wire. A copper screw D then taps into both the strap K and rod C, thus making a clean, fresh screw connection between them; a careful measurement of the total resistance is now made, the amount of necessary correction noted and the head again slipped out. A very few trials will suffice to get the desired resistance with great accuracy.

The heavy copper end straps to which the ends of the bridge wire are soldered, are coned very tightly upon the shafts of the cylinder. These end shafts are of solid copper $\frac{1}{2}$-inch in diameter, and revolve in heavy copper bearings brazed directly to the straps going to the commutating attachment. On the inside of each bearing is formed a massive mercury cup in which revolves a copper ring $1\frac{3}{8}$ inch in diameter and $\frac{1}{8}$ inch thick; these rings are sprung upon each end bearing and fit very tightly. Over half a square inch of their surface is always under the surface of the mercury which is always kept at the same height. The surface of copper contact is so large and the thickness of mercury so small that the resistance at these places is negligible; it is also constant. A sliding brush contact will not answer for work of this kind as the contact resistance is apt to be variable. In order to prevent the mercury from spreading, by capillary attraction, over the adjacent copper surfaces, each copper ring is clamped just outside the shaft between rubber washers, recessed, and filled with sticky wax; this wax pressing against the copper will, it is hoped, aided by the thick bands of lacquer, keep the mercury in its proper place.

Particular attention must be drawn to the fact that every particle of metal forming, in any way, part of the circuit or in contact with it, is of copper in both the commutator and cylindrical bridge, with the exception of the wire itself. This is necessary not only to keep the resistance of the circuit small, but also to avoid thermal currents and contact E. M. F.'s. In the earlier apparatus referred to in Part I. of this paper, it has been impossible to do the highest grade of work without thoroughly wrapping a large part of it in cloths or paper to keep down the thermal currents, and this, despite the fact that about the only metal except copper was in the binding posts. These, however, are sufficient to generate disturbing E. M. F.'s of sufficient magnitude to effectually mask the results desired, and it was seen to be imperatively necessary to get rid of this *entirely*. In the present apparatus the binding posts, connectors, cups, shafts, shunt rods, C and K, the terminal blocks of the shunt coils etc., are all copper; only the junctions of the wire itself can possibly give trouble, and this, experience has shown, need not be feared in the cylindrical bridge.

It is obvious that by simply replacing X and S, Fig. 1, by negligible resistances we convert the arrangement into the simple Wheatstone bridge; hence, in the apparatus in Fig. 3, we need but to place short, heavy copper wires in place of the standards on each side to enable us to use the device for ordinary work.

Often it is desirable to measure *spools* of wire quite accurately, say, to $\frac{1}{20}$ per cent., as, for instance, in the adjustment of a high grade resistance box, where the coils must be as accurate as possible before putting into the set, since any adjustment *then* would involve the loosening and re-making of a soldered joint and entail much inconvenience. With this apparatus this work can be done in one-fifth the time necessary with the usual apparatus and with a more certain accuracy. Since, in such case, it would not be worth while to solder wire ends to heavy coppers for immersion in the mercury cups, and since, indeed, the accuracy wanted does not require it, binding posts have been provided for this purpose just back of the mercury cups. These posts are of the "double grip" style, designed by Queen & Co., and shown in section in Fig. 8, and will catch the finest wires securely, either in the hole A, or between the surfaces K; the resistance of quite heavy copper conductors can thus be measured.

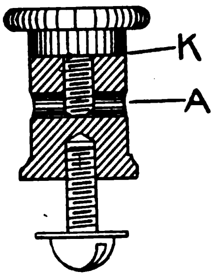

FIG. 8.

Many results obtained with and showing the performance of this apparatus might be given. The following, transcribed from one of our laboratory note books, is sufficient, however, to show the exceedingly high accuracy obtainable. It is the record of a standardization of a coil recently sent to us by one of the large universities for an exact determination of its value. The data, as will be observed, were obtained on four different days when, of course, minor conditions and the personal equation were likely to be very different:

ELIOTT OHM No. 106.

" "	(*f*)	0.98521	18°.1C		
Nov. 7, 1892	(*g*)	0.98559	18°.1C	(*g*) and (*h*)	$\frac{1}{500}$%
" 10, "	(*h*)	0.98592	19°.5C		
" " "	(*i*)	0.98588	19°.3C	(*g*) and (*i*) (*h*) and (*i*)	$\frac{1}{1000}$% $\frac{1}{1000}$%

DETERMINATION OF TEMPERATURE COEFFICIENT.

(1)

From (*c*) we have 0.99106 ohms at 42.°1 C.
" (*e*) " " 0.98517 " " 18.°0 C.
Difference is 0.00589 ohms for 24.°1 C.

$$\therefore \quad \text{Temp. coeff.} = \frac{0.00589}{24.1 \times 0.98517} = 0.000252.$$

(2)

From (*d*) we have 0.99121 ohms at 42.3 C.
" (*f*) " " 0.98521 " " 18.1 C.
Difference is 0.00600 " " 24.2 C.

$$\therefore \quad \text{Temp. coeff.} = \frac{0.00060}{24.2 \times 0.98521} = 0.000252.$$

Summary.—Between Oct. 28 and Nov. 7 the temperature was, at times very low. This caused the increase noted in (g), (h) and (i) over (e) and (f). The fall between (a,) (b), and (e), (f) was due to the heating to which the coil was subjected in (c) (d). This coil, No. 106, was of platinum silver and this *permanent increase* if subjected to low temperatures, and decrease if to high, are well-known characteristics of the alloy. The present value of the coil is given by (*g*), (*h*), (*i*); this value holds providing the limits 12.°0 C and 25.°0 C are not exceeded. After noticing the permanent change in resistance above referred to, I wrote to Prof. H. S. Carhart, who had sent us No. 106, telling him of it and saying that it probably occurred as a result of the heating necessary in getting its temperature coefficient but did not give him the coefficient we had obtained. In his letter of reply he said: "I meant to tell you not to heat the standard as we have very carefully determined its coefficient. It is not over 0.00025, I think." This, as contrasted with our value given above, is a difference of but $\frac{1}{5000}$ per cent. and shows what close work can be done with the apparatus in the hands of different observers in different places at different times.

A MERCURY ARC LIGHT.

Some interesting demonstrations were given at a recent meeting of the Physical Society of Berlin by Dr. Arons, who exhibited an arc light between mercurial electrodes in *vacuo*. The light was of a very brilliant quality, but was rather unsteady at the anode. No variations were observed at the anode when its intensity was very nearly equal to that of an ordinary commercial arc light. In spite of this, however, the temperature was by no means high; it was hotter at the cathode than at the anode. A spectroscopic examination of the light disclosed the existence of a yellow, a green and a blue line, but nearly 20 new lines were observed in addition to those due to the incandescence of the mercury. Some researches on the use of amalgams of mercury are in progress, from which some interesting results may be expected; already fairly good results have been obtained with sodium amalgam. The "telephone method" showed that the current is discontinuous, but no measurements of the resistance of the arc have yet been successful.

PHOSPHORUS MAKING BY ELECTRICITY.

An invention referring chiefly to improvements in the extraction of phosphorus by electrical furnaces has recently been elaborated by Mr. T. Parker. The object is to overcome the objections arising from the condensation of this substance in the upper part of the charge of such furnaces. The improvement consists in making the upper part of the furnace a sort of retort, which is heated to retain the charge in this part at such a temperature as to prevent the condensation of the phosphorus. This process claims to economize the electrical heat in the arc of the furnace.

THE ACTION OF AN ELECTRIC CURRENT IN DISPLACING A MAGNET ON MERCURY.

This subject has recently been brought before the Paris Academy of Science by Mons. C. Décharme in a short paper, in which he states the results of some observations recently made by him. The more important of these, says the London *Electrical Review*, may be summed up as follows:—Using perfectly pure mercury (an essential condition) for supporting a magnetic needle and leading the current into the mercury by dipping conductors carrying it into the mercury at different points, it was found that before assuming the position of equilibrium and thus conforming to the well known law of Ampère, the needle travels here and there over the surface of the mercury in a curious way, which appears to be governed by the ease with which it can travel in a direction parallel to its longer axis, and the difficulty of moving in a direction perpendicular to this axis. One of the most interesting effects was produced by making the current cross the surface in a direction perpendicular to the longer axis of the needle, with the negative pole of the current on the left of the south-seeking pole of the needle. Under these circumstances it was observed that the needle first moved away in a direction parallel to its longer axis, then turned round and finally returned, taking up the normal position according to Ampère's law. The paper in which these and other results are arranged may be consulted in the *Comptes Rendus*, Vol. cxv., No. 18, pp. 651—52.

NEW YORK YOUNG MEN'S INSTITUTE

In the educational department of the Young Men's Institute, of the Young Men's Christian Association of the City of New York, 222 and 224 Bowery, much attention is being given to technical studies, and the work is becoming more and more valuable to mechanics and artisans. The evening classes in electricity, steam engineering, carriage drafting, mechanical drawing, shorthand and typewriting, vocal music, free hand drawing, arithmetic, bookkeeping and English grammar have an enrollment of almost three hundred young men. The Institute committee of management and the Carriage Builders' National Association award prizes, diplomas and certificates of progress.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XV. NEW YORK, JANUARY 4, 1893. No. 244.

ELECTRIC POWER TRANSMISSION SCHEMES ABROAD.

THE heroic manner in which the utilization of Niagara Falls for industrial power purposes has been attacked in the United States has evidently stimulated foreign capitalists to consider more seriously the utilization of available powers abroad. Among the most recent of these schemes is the enterprise for utilizing the water power of the river Rhone in France, by converting it into electricity for distribution in the city of Lyons and its suburbs. It is proposed to construct a canal tapping the waters of the Rhone about 17 miles above Lyons, and to bring this diverted stream down to a point just outside of the city. Here there will be established 20 turbines of 1,000 h. p. each, which will be coupled to dynamos. By this means, it is hoped to infuse new life into the industry of silk weaving in the homes of the workers, by furnishing them with cheap power in small units, and thus to counteract the influence of large factories to which weavers have found themselves driven by the sharp competition of wholesale producers making an inferior product. In this case as in that of Niagara, at least as far as contemplated at present, the manufacturers will be within comparatively a short distance of the generating dynamos.

But another scheme, proposed in England by Mr. B. H. Thwaite, in a paper read before the Manchester Association of Engineers, is now being brought forward, and it appears to be so well advanced that specifications from a number of well known firms have been asked for. In its essentials this scheme is not new, being that suggested some time ago, namely, the burning of the coal at the pit mouth, the conversion of the thermic into electrical energy on the spot, and the transmission of the current over long distances. The details of Mr. Thwaite's proposal however, are decidedly interesting. In the first place it is proposed not to burn the coal under boilers and to employ steam engines, but to convert the solid fuel into a gas; second, to abstract the nitrogenous value from the fuel and convert it into agricultural fertilizers; third, the direct combustion of the fuel gas in the cylinder of the gas engine; and finally the driving of dynamos by means of the gas engine.

While we are not placed in possession of the detail figures, Mr. Thwaite claims that by his method of operation, 1 h. p. hour could be obtained with the expenditure of from ⅝ to 1 pound of solid fuel, owing to the high efficiency of the gas engine; moreover, the fertilizing value from this fuel would be equivalent to the nitrogen contained in from 22 to 28 pounds of ammonia sulphate. Indeed it is claimed that for power delivered in London from the Midlands, the coal consumed would only figure as two per cent. of the entire cost of power as delivered.

Mr. James Swinburne has prominently identified himself with this scheme, which appears to be thoroughly feasible, and well worked out. The conditions prevailing in England—the most compactly settled manufacturing country in the world—make it particularly adapted for such a system of power distribution from town to town. The route laid out for the electric lines embraces many small but busy manufacturing towns where power could be distributed at a profit.

While, as above stated, the distribution of power from Niagara, as laid out for the present, does not contemplate transmission beyond a radius of about 25 miles, it does not by any means follow that this will be the ultimate limit. On the contrary, with the knowledge and experience already gained with high tension currents, distribution at far greater distances may be looked for at an early date. In the same way the distribution of electricity from the coal pit is quite applicable to conditions as they exist to-day in this country, and, we may add, has even been contemplated in certain quarters. The English scheme, if put through, cannot fail to have a marked influence on the entire industry, and it is to be hoped it will find its realization in the near future.

STORAGE BATTERIES IN CENTRAL STATIONS.

WE give space in this issue to another communication from "Gautherot" on a subject which we are convinced will, sooner or later, occupy the serious attention of central station managers in this country. The reasons which have militated against the use of storage batteries in this country have already been discussed by us quite frequently of late and are alluded to by "Gautherot," who also gives some additional facts, the force of which will be recognized by all thoughtful students of the storage battery situation in this country. Our contributor holds, in effect, that the storage battery companies themselves are largely to blame for the condition of affairs existing to-day in the United States, and that being the case, he boldly asserts that a company willing and able to furnish the desired article on strictly business principles need fear but little from those claiming a right to the monopoly of this valuable adjunct to electrical distribution.

THE STROWGER AUTOMATIC TELEPHONE EXCHANGE SYSTEM.

BY

H. W. Underwood

SINCE the telephone has come into general use, there have been a number of improvements made, not only in the transmitter and receiver but in the form and style of switchboards used for making the several connections. Enough has been said by others regarding the old style and form of multiple switch boards, without making it the subject of this article.

What I desire to describe here is a new and improved apparatus, known as, "The Strowger Automatic Telephone Exchange Switchboard," whereby all connections are automatically made through the closing of the electrical circuit by means of a key placed upon the table of the battery box on each telephone. Placed at a central point are as many of the automatic switches as there are telephones in the exchange, each switch being connected with a telephone.

Let us first dwell upon the electro-mechanical part of the system, namely, the automatic switch. This is a small machine, measuring 6 x 3½ x 4½ inches over all, giving 500 connections, and containing four electromagnets, each having the same electrical resistance. To the armature of each magnet is attached a lever and near the end of this lever, a pawl, which, when the armature is attracted, falls into place in a ratchet wheel which is attached directly to the shaft of the switch, at the extreme end of which is a contact arm which connects the several lines together when moved into position by manipulating the keys at the telephone. At the extreme end of the lever is a dog which prevents the shaft from turning more than the desired distance, that is, not more than one point when the "units" key closes the circuit, or more than 10 points, when the "tens" key closes the circuit. The operating of the several keys, will be explained in detail later on.

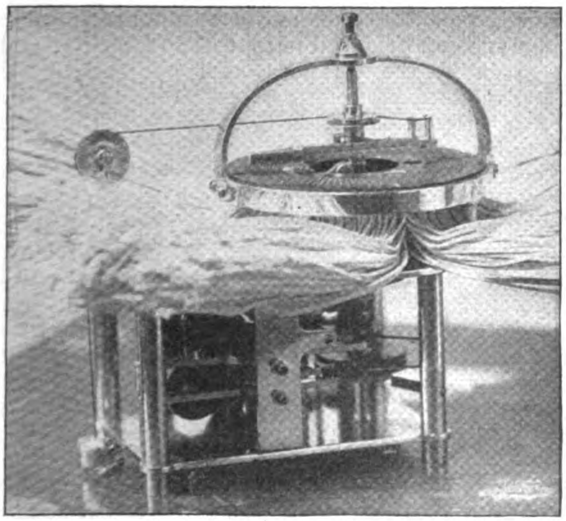

FIG. 1.

Upon a small rubber disc in circular rows of 100 and extending about $\frac{1}{64}$ of an inch above the surface of same, are located the several phonic wires of the several telephones connected with the exchange. Fastened to the end of the shaft to which the cog wheels are fastened, is a contact arm, by means of which the several phonic lines are connected with the telephone from which the call is sent out.

The movement of this arm is circular, being pivoted at the shaft; and as the arm moves around from its normal to any of the phonic lines, it takes a step by step movement, thereby doing away entirely with all friction, which, if it were not for this step by step movement, would be a serious drawback in many ways. In all other systems of automatic exchanges, friction has been so great that when put into practical operation they would not work, and were so cumbersome that a very few could be put into a good-sized room. But when we take into consideration the extremely small amount of space occupied by the Strowger automatic telephone exchange switch, and that there is no friction, and that the space is actually reduced to a minimum, one can readily see how simple and practical an automatic exchange must be.

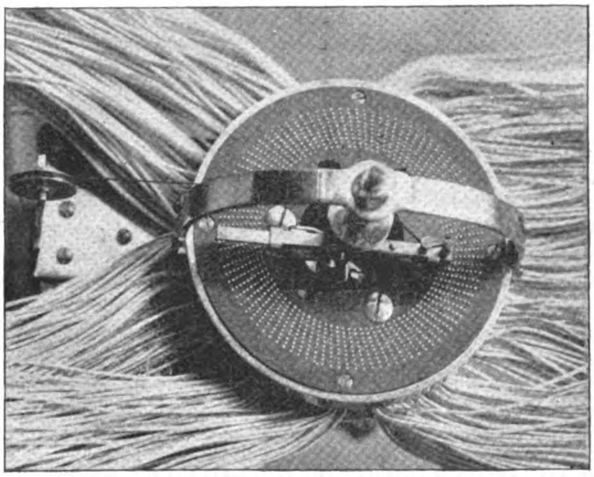

FIG. 2.

The keys or buttons which are placed on the battery box of each telephone, and mounted upon a thin rubber plate, are five in number, marked as follows: "1000," "100," "10," "1," "R." With this size of key board, 10,000 connections can be made, which will cover more than the largest exchange in the world to-day. The calling is done on a decimal system and the largest decimal in any desired number is called first. For example, in calling No. 1231, one closes the "1000" button once, the "100" twice, the "10" three times and the "1," or unit, once. There has been then automatically established direct communication with telephone No. 1231; then at the conclusion of the conversation, by the closing of the release button marked "R," the contact arm on the switch is automatically returned to its normal position.

The accompanying engraving, Fig. 1, shows the machine complete for 1,000 connections. The wires which project from under the disc are the several phonic wires or bank wires, as they are termed, when an exchange is set up, running to the several phones. Fig. 2 shows the surface of the rubber disc and the ends of the several phonic lines projecting about $\frac{1}{64}$ of an inch above the surface. The contact arm can be seen close to the shaft and attached to same, being there shown at its normal point, ready to be called by any of the other telephones, or to be connected with any of the phonic lines on the surface of its disc. The small weight which can be seen in Fig. 1 is used to bring this arm back into its normal position. The movement from one circular row to the other is operated in the same way as from one phonic line to another in the several rows, each row, as I have mentioned before, containing 100 wires. The space occupied by this 1,000 connection machine is about ¼ of an inch larger in the disc only, than that occupied by the machine for 500 connections.

I might mention in closing that La Porte, Ind., has today the first perfectly working automatic exchange system in the world, the opening of which was noticed in THE ELECTRICAL ENGINEER of Nov. 16. This system fully demonstrates in a thoroughly practical manner the many advantages obtained in the use of an automatic telephone exchange system.

THE EFFICIENCY OF ALTERNATING PLANTS.

BY

Harris J. Ryan,

THE letter published in THE ELECTRICAL ENGINEER, of Dec. 14, 1892, relating to the performance of a small alternate current station gives some facts that are rather startling. The clearness with which the correspondent puts his case leaves no doubt in one's mind that there is something radically wrong somewhere.

His case amounts to this: He has 1,300 lights wired from 97 transformers, operated from an 1,100 volt circuit with a ratio of transformation of 20 to 1, and supplied with current from a single machine. His station instruments and lamp current meters are correct, having recently been passed upon by a competent expert. With these he finds for one month of 31 days a primary out-put equivalent to 120,490 secondary ampere hours, while his meter readings sum up for the same time but 72,560. The difference valued in the selling price of a secondary ampere hour amounts to $479.30. His station out-put represents a retailing value of $1,204.90 per month, while he realizes but $725.60.

What the writer has to say is based on the assumption that the station instruments and house meters here used gave correct indications. Then, if we remove the transformer "leakage current" we must under all circumstances find a practical agreement between the ampere hours of the primary multiplied by the ratio of transformation as one quantity, and the ampere hours of the secondary as the other. That this may be realized by means of the station instruments and house meters supplied by makers of standard machinery is established through the results of a long and carefully conducted set of tests made by Messrs. Darlington and Cowan on the alternate currents circuits of a New York City electric lighting plant during April, 1892. After the transformer "leakage current" was removed from the primary ampere hours, this value, multiplied by the ratio of transformation, gave a result that agreed with the secondary ampere hours as read from the house meters to within one per cent. In the case before us then, the difference between the indications of the station ammeter and the house meters is to be accounted for as the "leakage current" of the 97 transformers.

If we assume that the full load capacity of these transformers is 1,300 lamps, or the total number wired on the circuit, which is usually about right for similar plants, the average maximum load for each transformer is 13.4 lamps. Tests reported in the Proceedings of the American Institute of Electrical Engineers, Vol. VII, p. 1, show that for the primary of a ten-light transformer, the ratio of the effective lamp current plus the effective "leakage current" to their value as measured by the ammeter, was 1.1. We shall make no serious error, then, if we assume that the same relation holds here. The sum of the primary lamp and "leakage current" ampere hours is 6,022 × 1.1, or 6,624. The secondary ampere hours for the same time were 72,560, and are equivalent to a primary lamp current of 3,628. The difference between them is 2,996, the ampere hours of primary "leakage current" for the 97 transformers. The actual current is 12 amperes, or .124 of an ampere as the average "leakage current" per transformer. This is a value that is more than twice as much as would be the case with standard makes of to-day. The "leakage current" for the above 10-light transformer of standard make for 1888 had a mean value for all loads of .127 ampere, and the average "leakage current" just deduced for each of the 97 transformers is in remarkable agreement with this figure. From the correspondent's account it is inferred that the plant has been in operation for several years, so that it seems reasonable to conclude that the average "leakage current" of .124 is about correct. The equivalent of this current as a lamp current would roughly be .8 of this value, or .0992, say, .1 of an ampere per transformer, a total of 9.7 amperes, and having an equivalent of 48,000 secondary ampere hours per month.

Numerous tests have been made and reports of them published on transformers produced during the present year by makers of standard apparatus. From these for the large sizes and from Sibley College theses of 1892 for the small sizes the following figures are obtained as the best results recorded:

PRIMARY PRESSURE, 1,000 VOLTS AT 133 P. P. S.

Out-put of transformer:		
In lamps.	In watts.	"Leakage current."
5	250	.040
10	500	.050
20	1,000	.055
40	2,000	.080
130	6,500	.100
350	17,500	.200

From these figures it is evident that by replacing the old transformers with new ones of the best make of to-day, using the larger sizes as far as practicable by connecting houses together, this loss may be reduced two-thirds. 32,000 more secondary ampere hours per month could then be sold to customers without increasing the current output of the station and without burning more coal. This would provide an additional revenue of $320.00 per month against which would be charged the cost of the additional lamp renewals, cost of inspection and the interest on the capital required for making the change and installing the lamps and transformers for the additional service. With this alteration accomplished, the secondary load would be 750 amperes with the dynamo at the full output of 80 amperes, and the figures given by the makers would be realized. This, doubtless, would have been realized from the beginning had a fair proportion of the larger sizes of transformers been installed.

The economy gained in adopting the largest sizes of transformers practicable in small plants that supply current to scattered customers should demand the same attention from the managers of these plants that it does from those who have the care of the large alternate current stations of the great cities. Cornell University is operating a plant of about the size under consideration. There are 1,300 lights wired, operated from 15 transformers with a maximum primary current of 35 amperes at 1,100 volts. The difference between the primary and secondary ampere hours is scarcely perceptible. We use two secondary pressures, 52 volts and 104 volts, with entire satisfaction. Where the secondary wiring is extensive, containing long runs, etc., a pressure of 104 volts is used. We do not clearly see why this plan for scattered customers has not been adopted more generally. Considering the ease with which two transformers may be used for a three wire sub-station, it is somewhat astonishing that this plan, likewise, has not been used more for distributing from the larger sizes of transformers.

AFTER considering the subject for some time the City of Dresden, Germany, has decided to erect an alternating central station, but the contracts for the work have not yet been signed.

ELECTRIC RAILWAY DEPARTMENT.

MAXIMUM SPEED ON ELECTRIC RAILWAYS.

BY

Chas. Steinmetz.

IN THE ELECTRICAL ENGINEER of Dec. 14, I notice an abstract from a German paper, in which the author, on theoretical grounds, limits the maximum possible speed of electric railways to 125 miles per hour, a figure which is so little beyond that reached by the steam locomotive, 97 miles, as rightly to raise a doubt as to its exactness.

Let me say that, especially at these high speeds, an electric motor can be made to yield any required power, so that the speed of the electric railway is undoubtedly *not* limited by the capacity of the motor. The limit of speed, however, is set by the ratio of train-resistance to adhesion.

A propelling force, revolving the car axles, will evidently cause motion, that is, acceleration only, when the *train-resistance* is *less* than the *adhesion*, while, as soon as the train-resistance is *greater* than the adhesion between wheel and rail (as specially noticeable on heavy up-grades), no acceleration, but slipping of the wheels will result. Since the train-resistance increases with increasing speed, while the adhesion may be said to be constant, at a certain speed a point must be reached, where the train-resistance equals the adhesion, and further increase of the propelling force results in no increase of the speed, but in slipping of the wheels. This critical speed, which can not be exceeded, even when all the axles are driving equally, is determined by the coefficient of adhesion and the train-resistance.

With regard to the coefficient of adhesion, the data at my disposition are necessarily limited. But I know, that with both car axles rigidly connected, a grade of 10½ per cent. can be climbed in all conditions of weather, so that the coefficient of adhesion is greater than .105, as witness the electric railway at Lynchburg, Va. With only one car axle driving, on the same grade under unfavorable atmospheric conditions, sand has to be used, though usually the car will start and mount the grade without sand. Assuming even two-thirds of the car weight resting on the driving axle, this represents a coefficient of adhesion of .16. Consequently, we can fairly count upon a *coefficient of adhesion* of about one-seventh or about 300 pounds per ton of weight.

With regard to the train-resistance, tests made on the Hudson River Railroad for speeds up to 70 miles per hour point to the formula:

Train-resistance, in pounds per ton $= 4 + .006\,N^2$, where N is the speed, in miles per hour. (Webb.)

Consequently if it is permitted to extrapolate by this formula, assuming all the axles of the train driving equally, we get: $300 = 4 + .006\,N^2$; or, $N = 220$.

That is, on our present steam railroads, with their heavy rails and well ballasted tracks, the electric motor can reach speeds up to 220 *miles per hour*, requiring at this speed 180 h. p. per ton of moving weight.

But, comparing these train-resistances with the much higher resistances met with in electric street railroading, we are entitled to say, that by the use of still heavier rails and better tracks than are to be found on our steam roads, the train-resistances may still be lowered, and a still higher speed made *possible*, though whether such a road will pay, is another question.

THE COMMERCIAL SUCCESS OF NON-ARCING METAL LIGHTNING ARRESTERS.

BY

Alexander Jay Wurts.

WHILE attending the recent Street Railway Convention at Cleveland, I had occasion to enter into conversation with a gentleman intimately connected with one of the largest electric concerns of this country, and among other things, I asked what his people thought of non-arcing metal lightning arresters. The reply which I received was to the effect, that they had tested the various metals and had failed to discover any marked difference as to their arcing qualities, in fact, that, as far as non-arcing metal was concerned, there "wasn't anything in it."

In regard to the existence of non-arcing metal, although the fact that its discovery was announced before the American Institute of Electrical Engineers would in the minds of many amount to conviction, possibly others, properly slow and conservative to accept such a radical departure from the well beaten path, will be interested in the abundant data now at hand, not only regarding the actual existence of this metal as announced before the Institute, but also as regards its successful use as a commercial article.

In THE ELECTRICAL ENGINEER of April 27, 1892, there was published an article on this subject in which will be found some excellent illustrations taken from photographs, and clearly showing the remarkable, and heretofore undreamed of, results obtained with varying lengths of air gaps; that is, with 1000 volts from an alternating current generator, it is not possible to maintain an arc over two air spaces of 1-32 of an inch each, and between non-arcing metal electrodes. When these air gaps are increased to ½ inch or 1 inch the arcs, when once established, will be maintained with all the fury familiar to users of high potential circuits. In the transactions of the American Institute of Electrical Engineers for March 15, 1892, there are some good illustrations, also taken from photographs, showing the different results obtained when using copper electrodes, and non-arcing metal electrodes.

A simple and interesting test illustrating the instantaneous interruption of the short circuit when using non-arcing metal, is made as follows: Across the terminals of a 1000 volt alternator connect two air gaps of 1-32 inch each, in series, the electrodes being made of non-arcing metal cylinders about 1 inch in diameter and having their axes parallel to each other. In series with these air gaps connect a 20-ampere fuse and a switch. Now bridge each of the two air gaps with a small crumb of tin foil, and throw the switch; the short circuit thus established will be so instantaneously interrupted that the fuse will not be melted, nor will there be a perceptible flicker in the lamps running from that generator.

The following test also illustrates, in a striking manner, the virtue of non-arcing metal. Connect five or six 1-32 inch air gaps as before, in series, and across the terminals of a 1000 volt alternator; then upon closing the switch the short circuit will be so instantaneously interrupted, that with six air gaps, three and often four of the tin foil crumbs will remain unfused. Had other than non-arcing metal been used under similar circumstances it is needless to say that the apparatus would have been instantly reduced to a shapeless mass.

Still another experiment, possibly more remarkable than the foregoing, was described before the American Institute of Electrical Engineers in the following words:

> Pairs of non-arcing metal dischargers were mounted upon thermostatic supports in such a manner that the dischargers of each pair normally rest in contact with each other, and so that any current traversing the system would be forced to pass through the thermostats and dischargers in series. The thermostats were so arranged as to cause the two dischargers in each pair to open away from each other upon the passage of the current. If then a single and permanent air gap were connected in series with this system, that is, an air gap just sufficient to prevent the normal pressure of the line from striking an arc, and, if an arc were started across it, the sudden rush of current through the thermostats would instantly introduce a number of air gaps in the circuit corresponding to the number of pairs of thermostatic dischargers, and thus automatically open the short circuit. This device was tested and found to work admirably. Of course, after the circuit had been interrupted, the thermos'atic dischargers at once returned to their normal positions. In fact, this action is so rapid that if a series of these dischargers be connected in short circuit without a permanent air gap, the circuit will be automatically opened and closed every two or three seconds. In order to appreciate the very remarkable action of this thermostatic device, it must be well borne in mind that with non-arcing metal a very small air gap is all that is necessary for the instantaneous interruption of a short circuit.

I have connected a device of this kind consisting of two pairs of dischargers across the terminals of a 1000 volt alternator and left it there for about 20 minutes, during which time a short circuit was automatically made and broken about every four seconds, without in any way damaging the non-arcing metal. The mere fact that these cylinders do not fuse together is hard to believe, and to this day it remains without a satisfactory explanation. That the short circuit should thus be repeatedly interrupted without vicious arcing, and without the instant destruction of the apparatus is conclusive evidence that "non-arcing metal" has properties very different from the metals ordinarily used for electric purposes.

EFFECT OF TROLLEY ROADS ON NEW YORK FERRIES.

A VERY decided boom is reported in the New York and Brooklyn ferry business. Officials of the Union Ferry Company say that at no time since the opening of the East River Bridge, in 1884, has the business at the ferries been as great as it is now. The reason is said to be the introduction of the trolley as a motive power for surface roads. So many people object to climbing the steps to the elevated stations, it is said, that they take the new trolley cars instead and go by the ferries.

Three of these trolley roads go to Hamilton Ferry, and as a result extra boats have been put on that route, and efforts are being made to get two ferry slips in this city instead of the one now in use at the foot of Whitehall street.

Very large and handsome boats have been put into commission on this ferry and they are crowded with passengers all day and very greatly overcrowded in the morning and evening hours.

When all the trolley roads get down to Fulton Ferry, where two of them now go, the ferry company expects to have double the boat service, and preparations are being made to put on new boats.

ELECTRIC RAILWAYS FOR MEXICO.

JAMES S. CLARKSON, ex-assistant Postmaster-General ; C. T. Meek, president of the Colorado Iron Company ; R. W. Clay, of Philadelphia, and T. H. Blackwell and G. H. Hobart, of New York, have been in the City of Mexico for several days recently, it is stated, negotiating for the purchase of the city and district railways, about 212 kilometres long. The documents have been signed settling the matter. The price is said to be $9,000,000. It is intended to work the railroad by electricity.

ELECTRIC TRACTION IN PITTSBURGH.

THE annual report of the Citizens' Traction Company of Pittsburgh, Pa., shows receipts of $683,471; expenditures, $455,880, and net $227,591. After expending $30,205 for improvements and paying 6 per cent. on $3,000,000 capital stock, there was a surplus of $17,334. The road is an electric line.

TROLLEY EXTENSION IN NEW YORK CITY.

BY a vote of 21 to 4, the aldermen of New York city have granted the following extensions of the trolley system, below the Harlem River, to the Union Railway Company : From the present tracks at One Hundred and Twenty-ninth street and Third avenue east to Second avenue, down Second avenue to One Hundred and Twenty-fifth street, west on One Hundred and Twenty-fifth street to Fourth avenue, up Fourth avenue to One Hundred and Thirtieth street, through One Hundred and Thirtieth street to Madison avenue, up Madison avenue and over Madison avenue bridge to One Hundred and Thirty-eighth street and Third avenue on the north side. Also a spur on One Hundred and Thirty-fifth street from Madison avenue to Eighth avenue (elevated station at One Hundred and Thirty-fifth street and Eight avenue.

MILAN ELECTRIC RAILWAY.

THE municipal council of Milan has granted a concession to the Edison Company in that city for the establishment of an electric tramway (any system), to commence at the Piazza del Duomo, and to terminate at the Porta Sempione. The experiment will be made for a year.

MISCELLANEOUS.

STORAGE BATTERIES IN CENTRAL STATIONS.

BY GAUTHEROT.

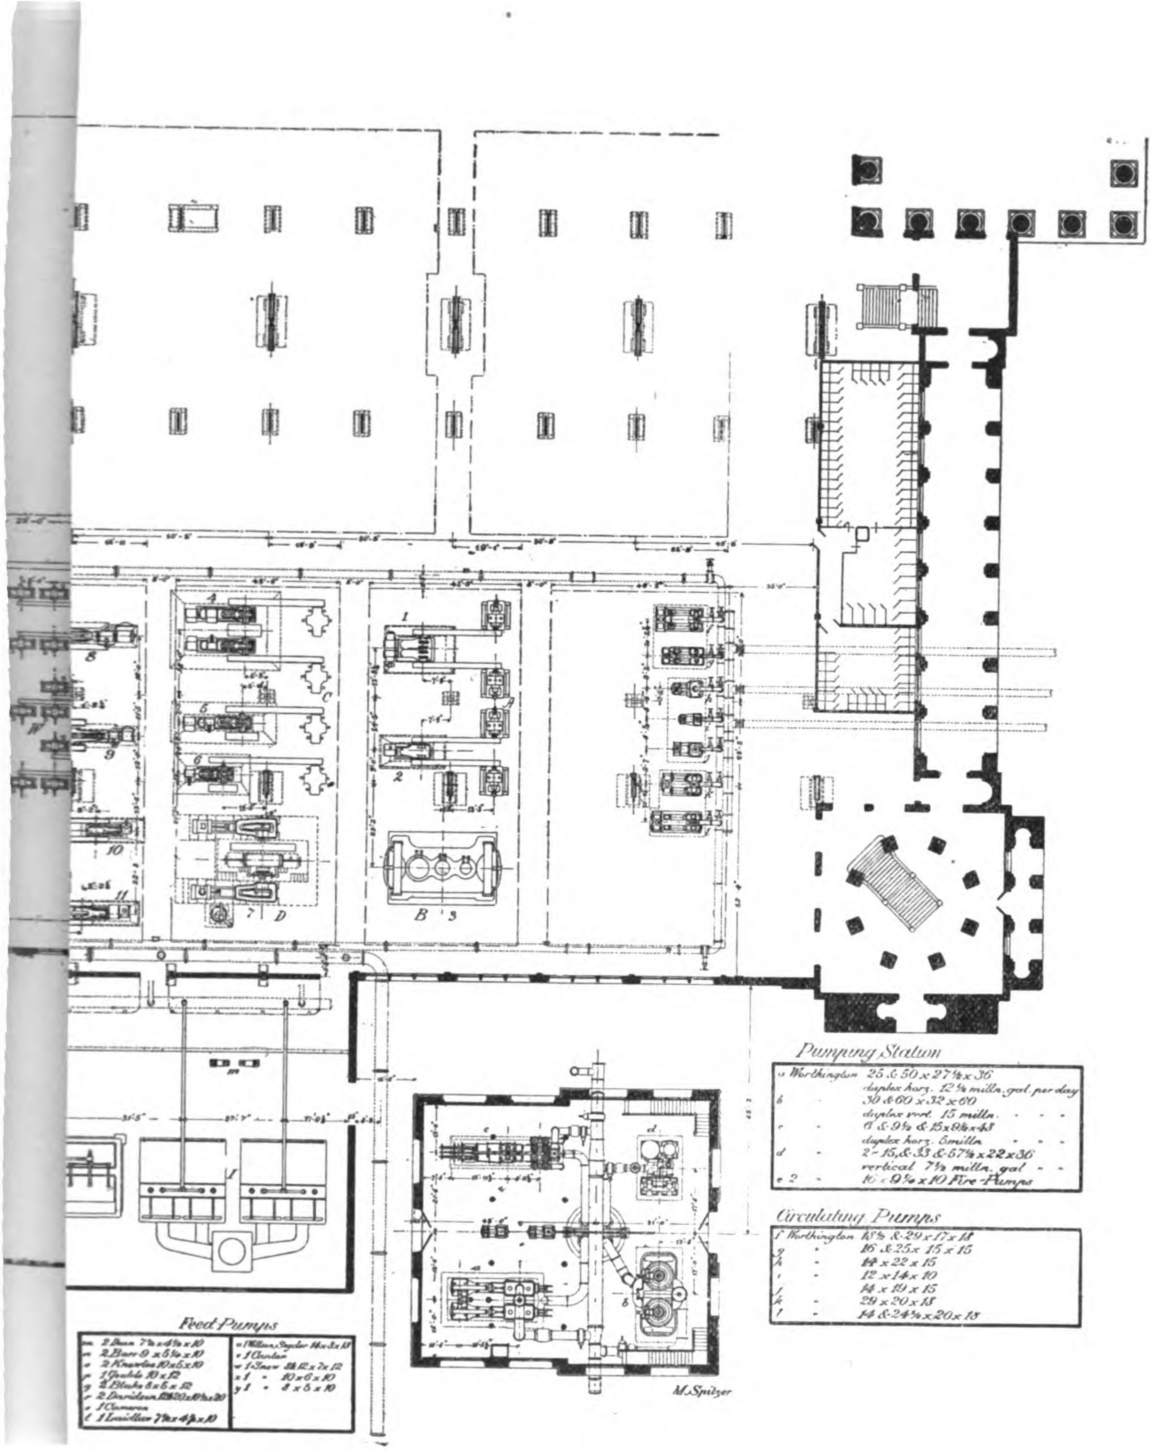
I HAVE followed with considerable interest the several communications which have appeared in your journal within the last few months on the subject of "Storage Batteries in Central Stations," and I must confess I was somewhat surprised at your remarks in the issue of August 31, regarding the impressions of an "American Electrical Engineer" upon the European accumulator plants.

As within the last few years my time has been about equally divided between the two continents and as I have had occasion to visit some of the largest accumulator installations in Europe, the impression left on my mind as to the "smallness of the plants" and the "extreme lightness of loads," is not in accordance with the views of the above mentioned "American Electrical Engineer." I think that some of the more recent publications on the subject of storage batteries in central stations, where there have been given some very interesting particulars regarding accumulator plants in England, France, Germany and Austria are in themselves sufficient proof that there do exist such plants which can scarcely be called "small" nor the loads they carry light. I must give "American Electrical Engineer" credit for having "unearthed" publications and particulars on the part of those who hitherto have apparently preferred to keep wonderfully silent. The fact of their now coming forward to face the public with facts, puts a very "healthy" aspect upon this most important industry.

There has been more or less a cloud of suspicious silence and mystery hanging over the accumulator business. It was not from the fact that the knowledge did not exist, and that the information *could* not have been given, but from the fact that those who could, would not, and those who would, could not. But is not this the case with every young industry, more especially where success depends almost entirely upon practical knowledge and experience and perfecting of details? Those responsible for each advance and who, by careful study and close attention, have acquired the necessary knowledge and experience are naturally not inclined to spread such knowledge broadcast. Then again, where success has been attained, as shown by some of the large installations in Europe, it has been mainly (I may say solely) due to careful study, care and management. For, after all, when all is said and done (notwithstanding the numerous and varied claims upon the subject of patents, construction, etc.), in many instances the materials used, and methods of manufacture of accumulator plates are not so widely different as to account for the successes and failures in working of different storage battery plants.

As a further proof of this, take the case of two companies in different countries, or even in the same country separated by only a few hundred miles, each manufacturing accumulators upon the same principle and under the same patents and each supposed to be working upon the same basis. What do we find? The one is a marked success and the other an utter failure. And what is the reason? Simply management or finance. Very often the former, but more frequently the latter, and very frequently both. In America, especially, storage battery companies have been organized and run upon the principle of too much paper and too little cash. Ninety-nine men out of a hundred who have "got in at 10 cents on the dollar" and are anxiously waiting for the moment to "get out at 20 cents" know no more about accumulators, their requirements and capabilities, than they do about ballooning. They have heard wonderful as to their possibilities prospects and capabilities un-

seen. If confident assertions by various manufacturers and ex-



statements as to their possibilities, prospects and capabilities untold; they have built upon the earlier statements, when repeating them to others, who again place further additions to the structure, until, after passing through a few mouths, the claims one hears made for some particular battery are enough to turn the hair of the unfortunate one remaining man of the hundred, who not only knows the facts but is probably responsible for the management, and what is worse, is expected to make the unfortunate accumulators fulfill each and every statement, expanded or otherwise.

Then again the ignorance of the public generally upon the subject enables competitors to make the wildest statements as regards the superiority of their particular wares in order to accomplish a sale. One frequently finds a would-be purchaser of some particular type of storage battery come to the would-be vendor with the statement that, a Mr. So and So has offered an equally good article, which will do equally good work at 25, 50 or even 75 per cent. less price; and what is he to do about it? If the would-be vendor offers to come down on his price, or if he advises the would-be purchaser to "take the other" the consequences are the same. The purchaser buys the cheapest. And what is the result? It is the case of a boy trying to do a man's work. The battery does very well for a short time, so much so, in fact, that, after finding it will run say 100 lights, the purchaser makes the wonderful discovery, or has been given the wonderful statement, that it will carry 120, yea more, 150, or even up to 200 lights for a short time. He tries it, not once, but frequently, until he finally acquires a habit of running more than 100 lights, whereas in reality 100 lights was nearly double what it ought to carry. He is delighted, and tells his friends. The purchaser of stock at 10 cents asks 15. Meantime the battery is receiving that abuse in working which finally results in a general break down. This results in an all-around abuse of storage batteries in general on the part of the purchaser and of the vendor of this special one in particular.

Not only in electric lighting but also in electric traction the fact that a storage battery is capable of being discharged at a far higher rate than is good for it, has proved one of the chief causes of its failures. No wonder one so often hears the remarks: "Storage batteries! Don't touch them!" "No good, and never will be." "I have tried them,—never again." "No! go, and buy engines and dynamos, but keep off storage batteries," etc. And yet this is all wrong, radically wrong. In some cases engines and dynamos may be more adapted to the work than the use of accumulators, but, as one of your correspondents lately remarked, neither the days and nights, nor yet the habits of the people are so vastly different in the United States and Europe as to make it a universal fact that accumulators are *not* adapted to central station work in America, whereas they *are* so adapted as well as adopted in Europe.

But all their outrageous claims, mismanagement, stock jobbing, competition in prices, etc., have been gone through in England, France, Germany, Austria, etc. It is the old story repeated. What has taken place there will most assuredly take place here. When sufficient people have been bitten and taken in, by believing wild statements; when the subject is a little more understood by the public in general; when companies are started upon sound business principles with competent management and plenty of working capital and when such companies will give substantial guarantees *which they can carry out and be responsible for*, and when purchasers of storage batteries are fully convinced that the cheapest is not the best; that for given work to be performed there is required a given weight of battery in order to ensure the cost of maintenance being within given limits,—when all this has taken place, as it inevitably will, we shall see the accumulator stations in America, on just as large, and in all probability much larger, a scale than any existing, or even dreamt of, in Europe.

I can hear some one whispering, "How about the patent question? Has this not had a great deal to do with checking progress, hampering finances, swallowing up funds and making things generally unpleasant?" I could perhaps say a good deal more than I care to on this subject but I will simply ask, Is the position in America so widely different in this respect from that of any European country? I can from my own personal knowledge say, that if decided statements as regards unassailable positions, broad claims, threats for payments, threats for compensation and royalties, etc., in fact, a general and universal system of attempting to induce the public to believe that each and every man who owns a battery is the one and only man who can or ever will be able to supply batteries,—if, I say, this has anything to do with and carries any weight, I can only add that I have heard as much of this in Europe as in America. Still they exist, all and every one of them. It is true some have been swallowed up or merged into others but still the fact remains that there is more than one accumulator company doing business in each of the various European countries, and in many instances in the same city. Each has been stating that its competitors will soon stop, but somehow they do not stop. It is also true that there have been some very important decisions in the United States Courts lately as regards storage battery patents, but whether this is going to result in the wholesale monopoly that some people imagine, remains to be seen. If confident assertions by various manufacturers and experts are proofs, there is likely to be a very lively competition in the accumulator business in the near future.

Having studied the question very carefully I am forced to admit I see little fear of the public being afflicted with an almighty monopoly in storage battery manufacture. We may see a little more litigation, a little snapping and barking, but I confidently anticipate seeing before long a thoroughly healthy competition in this business. As a matter of fact, there is room for all, and has been for a long time, and I doubt whether the "pull devil, pull baker" system would have gone as far as it has, were it not for the opportunity the various decisions in the Courts gave to various holders of stock of making some pretty quick turns.

How much better it would have been if a few honest dividends had been earned first and the matter of litigation postponed until the real and true value of any special type of battery had been first proved by actual practical work. If after satisfactory proof any special company considered their position sufficiently sound and ultimate prospects worth the expense, then would be the time to endeavor to stop infringers. I think it will be found that in Europe the companies doing the best business have never taken the stand of the aggressors in court. If assailed, they have answered. If assailed again, again they answered. And yet they survive. This fact alone appears to me to prove not only the folly of carrying litigation too far but also that accumulators are a success and capable of surviving many a hard knock.

It must be confessed that Americans with their usual spirit of go and enterprise tackled the most difficult part of the problem first. It was a case of trying to run before they could walk, in facing the problem of storage battery traction before having acquired more experience in the application to lighting on an extensive scale. At the same time there is more sound work being done in this line in America than some might suppose, though not on such a large scale as in Europe, it is true. It is a remarkable fact how very quiet some of the companies doing such extensive and prosperous work in Europe have been on the subject. I can quite understand how it is possible that "American Electrical Engineer" might very easily have missed seeing some of the large plants. I remember an instance of one of the largest existing accumulator plants of which I had never seen any accounts or publications and which I discovered by accident. Upon doing so I inquired of various people who, one would think, ought to have known something of it since they lived within but few hours' journey by rail, and to my surprise they had never heard of it. The fact is that when a substantial company is doing a good, honest and profitable business, where the stockholders look upon their holdings as investments, they are not so anxious to "noise abroad" the fact.

At the present day Europeans have learnt and Americans are quickly learning that the best batteries, and the only ones to be relied upon, are those which have a record of showing years of successful and profitable work. These are to be found at the present day and when they come to America it will be with all the advantage of experience acquired and practical details already worked out. I anticipate before very long to see some very large central station accumulator plants in America in which it will not be a case of having to wait before proving that success is possible, as this has already been done. And if Americans cannot do in this line just as well, if not better, what English, French, Germans and Austrians and every other nation has, then I shall "forevermore hold my peace" on the subject of using storage batteries in central stations in America.

DEVELOPMENT IN ELECTRIC METAL WORKING.[1]

BY FREDERICK P. ROYCE.

THE author described the principle of the electric welding by the Thomson, or incandescent, and the De Meritens, or arc system, and gave a brief historical sketch of the art of electric metal working since its first commercial application in 1888. The comparative cost of the electric and forge methods for carriage manufactories was then taken up.

The two important elements of electric welding are, he said, the labor at the welder and the power to drive the dynamo. The man who attends to the engine in all factories can easily look after the dynamo also, and only one man is required for ordinary work on the welder, with possibly a boy to assist him. In heavier work, such as axles, two men, one to weld and the other to reduce the burr under the hammer, can readily turn out 150 sets of one inch axles in a day, while 700 to 800 light tires per day can be welded by one man and a helper at low wages. Grinding and rolling were formerly tried to reduce the burr, but both proved unsatisfactory, and now hammering is found to be the cheapest and most effective method. A light power hammer is ordinarily used, though hydraulic presses have proved satisfactory in some classes of work.

The removal of ordinary oxides and particles of foreign matter has also been found unnecessary, though where heavy red oxides or serious accumulations of other substances exist, the metal should be cleaned. Pickling is resorted to where large quantities of metal are to be welded.

---

[1] Abstract of a paper read at the Buffalo Convention of the Carriage Builders' National Association.

The actual horse-power required is 25 h. p. for 45 seconds in the case of a round axle one inch in diameter, or 30 h. p. for 48 seconds for an axle one inch square. From this the cost of welding can be calculated where the price of fuel and labor are known.

The cost of the fuel used under boilers to produce electric current is almost always practically the same as that of the fuel used in forges for the same amount of work.

AN IDEAL CENTRAL POWER STATION.[1]—I.

BY C. J. FIELD, AND THE ENGINEERING STAFF OF THE FIELD ENGINEERING COMPANY.

It was with some reluctance that we accepted the title of this paper, realizing all that the words imply and the difficulty of fulfilling their requirements. We therefore have tried to carry out the idea as fully as possible by taking as a design a type of station which seems to indicate more fully than anything else the latest and prospective development of the best practice in central power stations.

We will, therefore, take the subject up and divide it into several different heads or divisions, and try in general to indicate, by the plans and specifications illustrated herewith, what we believe to be an ideal central power station, and will treat it by giving a brief general outline of the several points and close it by attaching to the paper what may be termed a sort of general specification covering the important points—as building, engines, boilers, generators and piping.

UNIT OF POWER.

The unit of power to be selected for the central power station is one of the first and most important elements to be considered after deciding on the capacity of the station. We have selected for this ideal station 6,000 h. p. as the total capacity. The question immediately arises, how many units of power shall it be divided into? We have found the following as a good rule to follow in deciding on the size of units, and that is, the number of units in any power station shall be the fewest consistent with safe and economical operation of that station. This shall be our foundation stone to build upon, and should be followed in the broadest possible sense. Experience has too often proved that power stations have been divided into too many units. This has been occasioned largely by two reasons: First, uncertainty of the development of the capacity of the station; and, secondly, inability or inexperience of manufacturers in the development and building of large generators.

The business now of building power stations and manufacturing the apparatus has reached such a commercial stage of development that both of these factors are eliminated. We now find capital ready and willing to invest in large power station enterprises, both for railway and general power work; also manufacturers with experience in machinery and ability to develop and build any commercial size of generator required or called for.

The unit of power should be proportionate to the size of the station, and in the size of station we selected we believe a 1,000 h. p. unit to be one which fulfills our requirements in every respect, both for safety and economy in operation. The engines are so built that where a small amount of power may be required for light loads late at night, the engines can be operated with economy on reduced capacity, even down to a few hundred horse power. This removes the necessity for one or two small units as has been customary to install in some stations of this class of work. They, as a rule, fill the space which could be taken by a larger size generator. A larger number of units proportionately than here laid out means additional expense in handling and caring for the machinery, also additional building space and real estate. The problem is now to concentrate all power into as few units as practicable.

DIRECT CONNECTION OR BELTING.

The problem is still in the minds of many people whether to use generators directly coupled to engines, or belted as in the earlier type of station. Formerly we had no choice in the matter. Generators, except in a few cases, were not built in this country for direct connection work in a commercial sense. We could only belt to the engine directly or through counter shaft. We do not propose to go into any extended controversy or argument on the three styles of connections, but only point out a few facts to be considered in this connection before deciding.

In a power station of the size herein indicated and located, as would generally be the case, in or about a large city, entailing considerable expense for real estate, and more expense for the building, the problem which at first reaches the engineer's mind is how to concentrate this power within as small a space as practicable without crowding, and also to economically operate the plant.

Looking at it from this point of view, the relative space required is, roughly, as two to one; in other words, a belted plant would require about five square feet of floor surface per horse power as against two and one-half square feet with direct connection plant. This means a saving of one-half the cost of real estate in building and also concentration of the power for handling. On the other hand, we have not secured flexibility of connection between the engine and generator, which we have in the belted plant, and the relief to the engine which is afforded by belt against the shocks of short circuits, etc. These are facts which should be more fully considered than they have been in the designing and building of a proper type of engine for direct connection. Ample fly-wheel capacity is one of the most important requisites for such an engine and ability to withstand direct shocks of short circuits and overloading of the generators. When these problems have been fully met, both theoretically and practically, we have no doubt that the development of the direct connection station will be rapidly extended. At present we are just beginning to enter what might be termed the era of direct connection work commercially, having as a basis for experience small practice in this country in special cases and a more extensive practice in Europe in this line.

POWER STATION BUILDING.

For power station building there are shown in Figs. 1, 2 and 3 general features and details of construction of a building adapted for this style and capacity of station.

The power station building is a factory for producing a commercial commodity and should be treated in that sense, the essential requirements being solidity of construction and protection against fire or any other accident to the machinery contained therein. The design of these buildings is too often placed in the hands of local architects, inexperienced and unacquainted with the requirements of such a building, and we find as a result many power stations in which the machinery has to be placed to fit the building, instead of, as it should be, the machinery laid out and the power station built to cover and properly protect it; being built, therefore, from an engineering point of view instead of an architectural one.

Without attempting to go into details or producing a regular building specification, we have tried, under the head of "Suggestions for Building Specifications," to cover the main features required in such a building.

BUILDING SPECIFICATIONS.

Excavation.—Excavate the entire space under the engine room to a depth of 10 feet, so as to get clear head room of 8 feet in basement. Excavate for all side, cross and gable walls, all foundations, and also central space between boilers to form a basement under the boiler room for ash and coal handling apparatus, flue and pipes.

Foundations.—If ground is good, lay base of concrete (four broken stone, two sharp sand, one hydraulic cement) and make footing courses of brick work or coursed rubble masonry of good, firm building stone, laid in cement mortar of three parts sand to one part cement. In case piling is necessary, test piles should be driven on different parts of the property in order to determine the bearing capacity of the pile under the conditions present, noting the amount the pile sinks under the last blows of the "monkey." Allow a factor of safety of from 4 to 15, depending on the conditions present. Piles should be of hemlock or spruce, perfectly straight and round, a 40-foot pile having not less than a 12-inch butt—the piles, after being driven, to have heads sawed off below mean low water to a uniform level; all piles in water to be capped with granite foundation stone, while those with heads in earth to be capped with a grillage of 12 x 12 spruce and 3-inch plank timber, and the whole filled with concrete well rammed. Lay foundation proper on this grillage.

Walls.—All walls should be of brick work from 16 to 20 inches thick, with pilaster at each roof truss, having at least 8 inches projection and 24 inches face. Carry these to a height of at least 25 feet, so as to allow clear head room of at least 20 feet below the traveling crane in power house. All brick should be burned and should have clean, sharp edges, no salmon or light-colored bricks being allowed. All brick work should be laid in cement mortar. The cement should be Dyckerhoff's or English Portland. All bricks in the face of the wall should be selected. All joints should be pointed. Pilasters on side walls of engine room should be built out by offsets and capped with stone binder for carrying rails of traveling crane. Set side ventilators in walls near ground line.

Roof.—The roof should be iron truss, riveted type, furnished with iron louvre, with side ventilator that can be operated from the floor. The top of louvre should be furnished with heavy hammered glass. The roof should be covered with Norway pine plank, splined and then covered with black slate of good quality laid with not more than five inches to the weather. All flashing around walls and all gutters to be of 16-ounce copper. The whole to make a weatherproof job.

Engine Floor.—The engine floor should be of two layers of plank, the first of yellow or Norway pine splined with hard wood, this floor to be covered with about one-eighth inch of plaster and with a second floor of seven-eighths inch second quality maple laid at right angles to the first. The first plank to be not less than eight or more than 12 inches and securely bolted by hook bolts at every beam to the iron I beams. The second floor should not be over four inches in width and should be blind nailed. All plank should be neatly fitted about all foundations and hand planed and smoothed and finished with two coats of boiled oil put on warm.

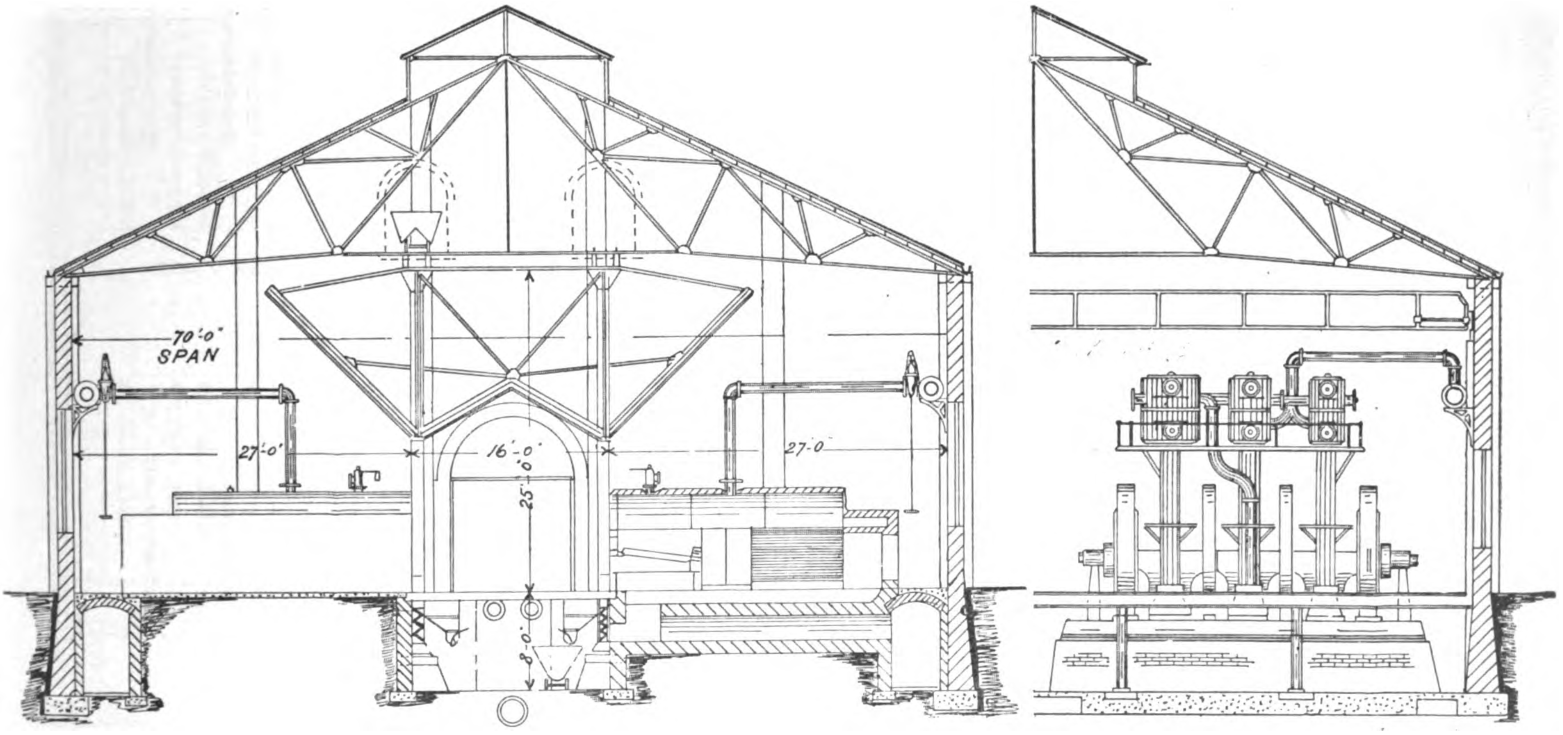
---

[1] Read before the Chicago Electric Club, December, 19, 1892.

Engine and Boiler Room, Basement Floor.—This floor should be made of not more than six inches concrete, well rammed and graded to drain, and finished by means of fine stuff floated smooth by means of a hand trowel.

The boiler room floor between boilers should be made of steel I beams covered by means of cast iron plates of suitable pattern. All other parts of the fire room should be finished by means of concrete cement same as basement.

Doors and Windows.—All floors or main doors should be of some wood ceiling and made, say, 2½ inches thick and finished with large wrought iron hinges (oxidized hinges and knobs). All doors in cross or partition walls should be made of beaded white pine ceiling laid diagonally and securely nailed, covered with a layer of asbestos board and then entirely covered with black sheet iron fastened by means of round-headed nails. These doors should be sliding with friction rollers, track, etc. All windows should have box frames and all sashes have four lights of American glass, best quality, well bradded and back puttied, fitted with noiseless pulleys, cast iron weights, brass chains and sash locks.



SECTION OF BOILER AND ENGINE ROOMS, FIELD IDEAL STATION.

Painting.—All woodwork should have not less than three coats of first-class lead paint ground in oil; this includes under side of roof, windows, doors, etc. All iron should receive two coats of metallic paint, one before erection and one after the structure is completed.

ENGINES.

Engine manufacturers and designers to-day are devoting their best time and attention to the development of a type of engine best adapted for electrical power work. We find, therefore, more progress being made this year and still more promise for the year to come than has been made in a number of years on this work. The old high speed engine has done well and the Corliss engine too. Present work and requirements seem to tend to a type of engine combining, it might be said, the good features of both, filling a middle ground and adapting itself more fully to the demands and requirements of large central station work with direct connection. Engines meeting these requirements are now being built and manufactured by such firms as the Lake Erie Engineering Works, Dickson Manufacturing Company, Cramp & Sons' Ship and Engine Building Company, Pennsylvania Iron Works Company, McIntosh & Seymour, E. P. Allis and other builders. We have tried to indicate the requirements of such an engine in the following specifications:

ENGINE SPECIFICATIONS.

Duty.—Electric railway and power work. All parts extra heavy.

Type.—Vertical, three crank, triple condensing.

Power.—Ability to develop for short periods of time a power of at least fifty per cent. above its rated capacity without dropping off in speed of revolution.

Regulation.—Regulation effected by means of a shaft governor acting on the valves of high pressure cylinder alone. Governor designed to cut off all lead of steam valves when practically all load is thrown off the engine. The momentary variation of speed of revolution (*i. e.*, the variation that would take place in three to five seconds) not to exceed 2½ per cent. when one-half of the rated load of the engine is thrown suddenly on or off; indicated by means of a tachometer belted direct to the engine shaft.

Economy.—Economy with condenser under average economical load, to be not more than fourteen (14) pounds of steam per indicated horse power per hour with 150 pounds initial steam pressure and 26-inch vacuum. This assumes that the steam is not to exceed 2½ per cent. of moisture and the first cylinder steam jacketed with full boiler pressure.

Valves.—To have four valves to each cylinder. The steam and exhaust valves to be independent, with exhaust valves moved by separate gear. Valves on high pressure cylinder to be either of the piston type or flat valve, balanced, with pressure plate. Valves on intermediate pressure and low pressure cylinders to be of flat type, either four ported, partially balanced grid-iron or Corliss type.

Clearances.—Clearances not to exceed eight per cent. in the high pressure cylinder and three per cent. in the intermediate and low pressure cylinders. Cylinders to be protected by non-conducting covering, such as magnesia or asbestos, and steel or cast iron jackets for finish. Cylinders in receivers to be protected by means of relief valves.

Frames.—To be castiron girder-type " *A* " frame.

Shaft.—Of best forged steel with built-up cranks and counterbalanced in one piece.

Bearings.—All main bearing surfaces such as shaft bearings, slides, etc., should be water jacketed.

Gallery.—Engine to be furnished with one or more galleries from which it can be operated as well as from the floor, and offering easy and safe means of access for lubrication and inspection.

Lubrication—Engine to be provided with either oil or grease lubricating apparatus, such that it can be lubricated as thoroughly when in motion as when at rest. Each cylinder to be provided with sight feed lubricators as well as oil pumps, and the entire engine, if oil is used for lubrication, to be fitted with sight feed lubricators. In the case of grease lubrication, provision is to be made to allow any part to be lubricated individually, as any system of grease distribution from a common centre involves the possibility of stoppage of tubes with dirt or foreign substances.

Fly or Belt Wheels—The engine should be provided with intermediate wheels between the cylinders where possible, so as to bring the shaft as near the condition of uniform load as possible. Allow 48 pounds per indicated horse power in the case of electric lighting and 70 pounds in electric railway and power work for weight of fly wheels. Rim of wheels on a basis of 5,000 feet velocity of the rim per minute. Piston speed 650 feet per minute.

Rotative Speed—A mean figure between a high, or what is commonly understood by high, and low speed; say 120 revolutions per minute on a 750 h. p. triple.

Remarks—The power the engine should develop when connected direct to an electric generator should be determined by the capacity of the generator first, and also its capacity for overload. The engine should have an ultimate capacity approximating that of the generator.

Experience has proved that an engine of large power can be regulated closely as regards speed of regulation, by means of a shaft governor acting directly on a properly designed valve and gear on the high pressure cylinder alone of a triple expansion engine. The governor should have a "gravity balance" in case the steam valve on the high pressure cylinder is placed in such a position that it is free to move vertically, as is generally the case in this type of engine. The governor should also have a centrifugal or "running balance" when the engine is in motion. As mentioned in specifications, the governor should be designed to cut off all lead of the steam valves operated by the governor, so that when practically all load is thrown off the engine, the governor will admit absolutely no steam to the high pressure cylinder, thus compelling the engine to decrease in speed by having only the remaining speed in the first and second cylinders to draw on, instead of the amount that would be admitted by the lead of the high pressure cylinder valves, as usually done to-day.

PLAN OF ENGINE AND BOILER ROOMS, FIELD IDEAL STATION.

The specifications for valves in the engine described follows logically when the regulation of the engine is obtained by means of a shaft governor, acting directly on the high pressure steam valves without the intervention of any intermediate gearing to assist the centrifugal force of the governor, thus depriving it of its sensitiveness with changes of speed. The piston type of valve is open to the objection of leakage, but inasmuch as any leakage would be expanded in the next two cylinders of a triple, the simplicity of the valve and its action under high pressure steam tends to balance this argument. It is essential to have the valve balanced on account of the high steam pressures used in this cylinder. The valves on the intermediate and low pressure cylinders, as already specified, would give a practically perfect steam distribution when moved by the eccentrics, and the engine can then be adjusted to the service required, be it condensing or non-condensing.

One of the most vital points of an engine for electric service is that of main bearings. They should have a surface velocity of not exceeding 350 feet per minute, with a mean bearing pressure per square inch of projected area of journal of not more than eighty pounds. This is considerably within the safe limit of cool performance and easy operation. If the bearings are designed in this way, it would admit of the use of grease on all the main wearing surface, which in a large type of engine for this class of work we think advisable.

In regard to the location of fly or belt wheels, we said in the specification that the engine should be provided only with intermediate wheels between the cylinders, so as to bring the shaft within the condition of practically a uniformly loaded beam. This will prevent excessive wear on any one main bearing of the shaft, and in that way allow it to become other than a straight line.

In regard to rotative speed it is a mutual condition between the engine and generator, and is too often determined by financial considerations. The faster speeds permit less cylinder condensation in the engine, but require a greater amount of care in the engine-room. The tendency to change among large engines of the type for which we are furnishing specifications is toward the medium rotative speed.

CHOKING COILS.

THE London *Electrical Review* says: There is eddy current loss of power in all the conducting masses of a choking coil. Hence a choking coil is really a transformer with one primary coil and many secondaries and much magnetic leakage. In a transformer with many coils, whether or not they have magnetic leakage, it may be shown that any given group of secondaries of a given number of turns and resistances may be replaced by one secondary without affecting the currents in the other coils; and we may take a choking coil to be a transformer with a primary coil of N turns, and resistance R ohms, with C amperes flowing at any instant, the potential difference at its terminals being V, and a secondary coil closed on itself of n turns, resistance r ohms, and current c amperes. The Proceedings of the Physical Society for October contains a valuable Note by Prof. John Perry, D.Sc., F.R.S., with an indication that we may shortly expect further contributions from him upon this interesting subject of choking coils. The treatment in this preliminary note is of a mathematical nature; equations being deduced which it will be useful to compare with those which are employed in practical transformer calculations. The Professor towards the end of his paper throws out the suggestion that in a choking coil we have, perhaps, found what has long been looked for—a method of increasing frequency by magnetic means.

THE STATUE OF LIBERTY.[1]

BY MAJOR D. P. HEAP, U. S. A.

WHEN the Statue of "Liberty Enlightening the World" was erected on Bedloe's Island, New York Harbor, it was found that no provision had been made to show a light, except possibly through the windows forming the diadem.

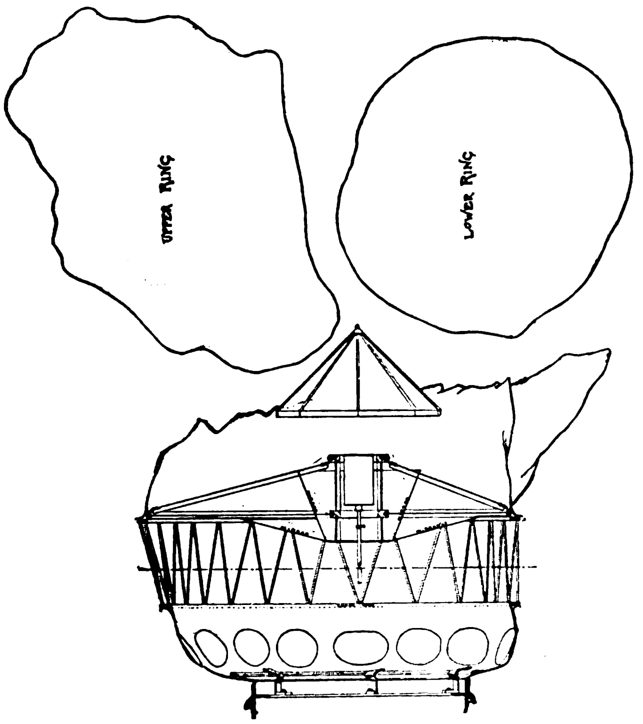
The statue consists of an iron skeleton covered with a copper skin, and stands on a granite pedestal in the centre of Fort Wood.

In the daytime it is a most commanding figure, as it is of colossal size, the combined height of pedestal and statue being three hundred and five feet.

At night it would be invisible unless illuminated by artificial means. The very name of the statue almost imperatively demanded that it should exhibit a light, and, as the right hand carries a torch from which flares an immense copper flame, the most natural thing to do was to make the flame luminous.

Various methods were proposed. One was to place electric lights on the balcony surrounding the flame, which by reflectors would throw their light on the flame, while the direct light would be screened from the eye of the observer.

This might have answered fairly well had the flame been gilded; but a serious objection was that these outside lamps would be exposed to all weathers.



NEW TORCH OF THE STATUE OF LIBERTY.

On Oct. 11, 1882, Lieut. John Millis, Corps of Engineers, U. S. A., proposed a plan contemplating exhibiting a powerful electric light from the torch to be visible around the entire horizon, and such an arrangement of lamps and reflectors at the salients of the fort as to throw light directly on the statue and pedestal, besides the necessary illumination of the interior of the statue and pedestal and the engine and boiler-rooms.

In order that the light placed inside the torch could be seen, it was necessary to provide openings; so two rows of circular windows, like the port-lights of a vessel, were made in the copper flame. This plan was approved, and was so promptly carried into effect that everything was in readiness for the inauguration ceremonies, which took place on November 1, 1886. Mr. Bartholi visited the island on that night, and expressed himself as entirely satisfied with the effect of the illumination. He appreciated the difficulty of making the statue itself visible by reflected light, owing to its dark color, and had certain other ideas in addition in regard to its illumination.

After quoting letters from Mr. Bartholdi, in which he suggests, among other things, placing a supplementary light in the head of the statue, Major Heap continues:

Experiment has shown that the project of placing a light in the head does not have the effect anticipated by Mr. Bartholdi: the appearance is simply that of another light below the one in the torch.

The effect of the side-lamps is to illuminate quite satisfactorily the pedestal, which is of a light-colored granite, and to bring out the details of the statue when the observer is close to it.

If the statue were painted white it would be seen very clearly, and I believe the effect would be very striking, especially at night, and in addition it would check the corrosive action of the copper, which has already taken place, as is shown by the green streaks on the pedestal.

I was anxious that the method of lighting should be improved, and at the same time to carry out as far as practicable the ideas of the artist.

I submitted my views to the Light-House Board. They were approved; and in consequence the following notice to mariners was issued:

> Notice is hereby given that, on or about October 21, 1892, the following changes will be made in the lights and illumination of the Statue of Liberty Enlightening the World, inside Fort Wood, Bedloes Island, New York Bay, New York.
>
> In addition to the light now shown from the torch there will be a vertical beam of red and yellow light seen only by reflection from the haze or dust in the air.
>
> The face and bust of the statue will be illuminated by a powerful search light from one of the salients of the fort.
>
> The coronet will be decorated with red, white, and blue incandescent electric lights.
>
> The pedestal will continue to be illuminated as heretofore by arc lamps within the salients and not visible outside the fort.

As will be seen by the notice to mariners, the day for the first exhibition of the light was that set apart by the President as a national holiday. The flame originally contained eight arc lamps of about 2,000 c. p. each, and these could be seen only through the circular windows previously mentioned. Of course a very large proportion of the light is wasted, and the observer can see only that which streams through that window opposite to which he happens to be. These eight lamps are now replaced with one self-focussing lamp of 6,000 c. p., and for the circular windows is substituted a glazed belt of plate glass eighteen inches high.

Inside the flame are mirrors made of aluminum reflecting a portion of the light horizontally and the rest of it in a vertical beam through a skylight glazed with red, white, and yellow glass, the different colors giving it somewhat the effect of a flame.

The aluminum mirrors are corrugated, and the light reflected from their numerous faces seems to be of a diameter as large as the copper flame, and no longer looks like a bright point or star.

The making and fitting of the frame to hold the glass forming the glazed belt was the most troublesome and difficult part of the whole plan. It was done by first making patterns of the flame where the upper and lower rings were to go. These rings were then made in four pieces and fastened securely outside the flame to the iron frame inside by means of bolts passing through the copper.

After this was done, brass sash-bars were screwed diagonally to the rings, the copper was then cut away between the rings, and the glass panes put in.

The accompanying diagram will show how irregular in shape these rings had to be, and how difficult it was to fit them.

The lighting of the coronet or diadem was considerably simpler. Fifty incandescent lamps of 50 c. p. each are used, and the globes surrounding them have the national colors. There are twelve red lights in the centre, then six white ones on each side and thirteen blue ones over each temple. The effect is that of a crown of jewels composed of rubies, diamonds and sapphires.

NO SATISFACTORY BID FOR THE NEW YORK UNDERGROUND.

THE franchise for the proposed elaborate underground rapid transit system in New York city was put up for sale on Dec. 29, at the City Hall but only two bids were made, both coming from the same person, Mr. W. N. Amory, who offered $500 and $1,000, with ⅛ of 1 per cent. on the gross receipts of operation. The bid was not accepted. It is now expected that the Manhattan Elevated Company will make an alternative proposition, whether the franchise should or should not be put up again, on the underground plan. The road was to be run by electricity, but there is consolation in the fact that its non-construction will only necessitate further resort to the use of trolley cars. It is also likely that the elevated railway extensions will have to be operated electrically.

IMPROVEMENTS IN THE NEW YORK POLICE TELEGRAPH.

THE Board of Estimate and Apportionment has given $47,000 to the Police Telegraph Department, the greater part of which sum is to be used to make a complete change in the telegraphing system. A year ago this department asked for $72,000 for this purpose, but got only $25,000. The appropriation now made completes the amount originally asked for, and the change will be effected at once. M. R. Brennan, at present assistant superintendant of the Police Telegraph Department, but who will become the superintendent-in-charge after January 1, states that the system which is to be put in use is practically that of the Stock Quotation Telegraph Company.

Mr. Brennan will have Mr. E. H. Murphy as his assistant superintendent. The respective salaries are $3,000 and $2,000 per annum.

---

[1] Abstract of an article in *Lippincott's* for December, 1892.

LETTERS TO THE EDITOR.

THE COMPOUND AND THE VARIABLE SHUNT MACHINE.

In your Dec. 21 issue, I note a letter from Mr. J. Stanford Brown in regard to compound wound machines. He opens his letter with this statement: "Let us have a little light on the subject of the variable shunt on the series field." It strikes me that, to use his own expression, he has "let very little light" on the subject by his letter. I do not wish to pose as a champion of the Thomson-Houston, or any other machine, but as an electrician, it seems very strange to me that anyone having the familiarity with the Thomson-Houston machine which Mr. J. S. Brown appears to have, could write such a letter on the subject under discussion, for he seems to overlook or ignore the usual object of shunting a series coil.

According to my way of thinking, it is a clear proof of a well designed machine if the so-called variable shunt can be removed from the series coil without "appreciably bad results," for its object is, not to waste a large number of watts, but to correct a very slight possible error in the ampere turns of the series coil,—an error not owing to fault of design necessarily, but rather, in the main, to the conditions which tend to make dynamos, particularly where cast iron enters into their construction, vary slightly in their electrical conditions.

This variation in well designed machines, should not exceed more than from 1 to 1½ per cent., and under any circumstances, not over 2. Now it is perfectly evident that a variation of 2 per cent. in the E. M. F. of the dynamo is, under ordinary circumstances, not going to cause "appreciably bad results." On the other hand, if the machine is sold and guaranteed for a certain E. M. F. the makers certainly want to make it right, even as close as within 1½ per cent.

Of course the remarks I make refer particularly to constant potential, incandescent dynamos and not to special machines which, for some good reason, are over-compounded. It is very evident to any electrician that shunting the series coil of a properly designed dynamo *will* vary the E. M. F. given out by the machine under part or full load and that the E. M. F. will rise or fall according as the resistance of the shunt is high or low, in proportion to the resistance of the series coil. If Mr. Brown found no variation on removing his so-called variable shunt, it certainly showed that the machine with which he was experimenting was unquestionably well designed, without having loss of energy wasted in watts or more pounds of copper in the series coil than was necessary to do the actual work required.

Mr. Brown evidently confuses the types of dynamos under discussion, having performed his experiments on standard machines, designed for constant E. M. F. and forgetting that it is often a great advantage in special cases to have a machine so designed that the E. M. F. can be maintained or varied at will, as the load is increased. This last condition is where the variable shunt to the series coil gets in its work. In the machine tested by Mr. Brown, the shunt, evidently, was not intended to be *variable*, but was adjusted once for all, and was supposed to be left to remain so.

I trust that I have made myself clear, and thrown a "little more light" on the subject under discussion.

J. F. Denison.

New Haven, Conn., Dec. 24, 1892.

THE EFFICIENCY OF ALTERNATING CURRENT PLANTS.

In your issue of Dec. 14, W. H. C. propounds a question upon station design and management which is not peculiar to his own plant. He finds a discrepancy between the station load, and the commercial value of the service given.

His first complaint, that the dynamo was supposed to supply five amperes for each 100 lights, is probably the result of misleading statements of an agent. It is possible to obtain this result, if lamps only are connected to the dynamo, without loss in the circuits, but the statement does not cover commercial conditions, including primary and secondary circuits and converters, each of which is a source of loss.

His assumption that 750 lamps on the secondary circuit, can be operated with 75 I. H. P., is hardly possible in practice under his conditions. He says that 97 converters supply 1,300 lights, an average converter capacity of less than 15 lights, and it is most probable that this size of converter or smaller is in the majority. Taking the above figures I think he will find the engine will indicate 80 H. P. at least, and most probably more, when 750 lights are "on." Calculating the efficiency of the plant on the basis of 50-watt lamps, it gives about 68 per cent., or a loss of 37 per cent. between the engine cylinder and the lamps. This loss may be divided about as follows: Engine and belt, 14 per cent.; dynamo and exciter, 15 per cent.; distribution, 8 per cent.

A large part of the loss which W. H. C. cannot locate is probably due to the use of so many small converters. These are known to be of lower efficiency than large ones, and besides this he has a large amount of iron upon the circuit which dissipates current as heat, and consequently this current which is recorded at the station has no commercial value. This loss becomes more serious to a plant with a long period of light load, and a short one of heavy load, as it does not vary with the load.

There is another point affecting the commercial value of a plant, which W. H. C. does not touch, but it may not be out of place to refer to it, and that is, the voltage used. I prefer to use 2,000 volts primary, and 100 volts secondary, and in most cases these conditions will improve the commercial value of a plant, taking only one-quarter the amount of copper to operate at the same loss; or the copper may remain the same and the loss reduced, the efficiency of all the apparatus remaining practically the same. Some people object that we cannot insulate 2,000 volts, but this I do not admit, as I have installed several plants of this type, all of which are successful. Even admitting this objection, there is no objection to 100-volt secondaries, and the consequent saving of copper. It is true that with 50-volt secondaries and lamps, the electrical efficiency is slightly higher, 13 per cent. as a maximum under the best conditions, but having regard to the large saving in copper and the first cost of installation, and, therefore, the smaller receipts required to produce a dividend, I think the balance is decidedly in favor of the higher voltage in most cases. Another point concerning 50-volt wiring is that generally the fittings are ill suited to carry the larger current necessary, and there is more heating of parts, especially fuse boxes, where fuse wire is used.

I have recently seen an aggravated case of W. H. C.'s complaint, where no larger converter than 15 lights had been ordered, and only a few of these. In this plant I have seen three and four converters bunched to supply a building.

Nemo.

THAT UNREMUNERATIVE ALTERNATING PLANT.

I wish to thank your contributors C. M. Green, A. W. Meston, and "N. W." for the information contained in their letters printed in The Electrical Engineer of December 28, as well as the correspondents whose private letters I have received through you. By an oversight in my former letter, the actual number of transformers, which is 77, was printed 97. These are as follows: 24 of 10-light: 31 of 20-light; 17 of 25-light; and 5 of 40-light, making an aggregate lamp capacity of 1,485. The lamps are 52-volts. In accordance with a suggestion of one correspondent, I tried the experiment of running the plant in the day-time with no load, and got an indication on the ammeter of over 12 amperes. Taken in connection with a computation similar to that given by Mr. Green, this led me to suspect a special leak. I set the dynamo running and disconnected one transformer after another, and finally found a defective one, the removal of which caused the reading to drop to about 3½ amperes. This was evidently the main source of the trouble. A comparison of the readings of a 40-light meter, which I placed in the 1,000-volt circuit with the station ammeter, indicates that "N. W." is correct in his statement that the power is liable to be overestimated when computed from the ammeter readings. The load which has been taken off from our dynamo does not compare with the load which has been taken off my mind.

W. H. C.

December 29, 1892.

PERSONAL.

MR. W. FORMAN COLLINS.

It is with mingled feelings of regret and pleasure that The Electrical Engineer announces the severance of its connection with Mr. W. Forman Collins, who for more than two years past has been its Western Editor and Manager. There are few electrical engineers of the same age his equal in ability and experience, and he has shown a judgment and a capacity for hard work that will help to carry him far on the road to success. He is still very young, but in the favoring air of Chicago has ripened quickly, winning his position by downright merit. He will now join the forces of the *Western Electrician* under such desirable conditions that the Engineer can only congratulate him and wish him God speed. His new duties connected with the active direction and management of our prosperous Western contemporary will bring him heavier personal responsibilities than heretofore, but he will be found in every way equal to the emergency; and he will in his larger sphere of usefulness and activity, broaden and develop in all the good qualities that have already taken him so quickly to the front of Western journalism.

Mr. H. T. Edgar, who has been connected with the New York Engineering Department of the General Electric Co. has resigned his position, and on January 1, will become manager of the Georgia Electric Co., of Atlanta, Ga. He will have charge of one of the largest and best plants in the South.

Mr. John A. Cross, consulting mechanical and electrical engineer of this city, has accepted the position of manager of the Geneva, N. Y., electric lighting station, and will shortly enter upon his duties.

OBITUARY.

CAPTAIN ALBERT GALLUP.

We regret to record the death of Capt. Albert Gallup, formerly Park Commissioner in this city, and late in command of the Signal and Telegraph Corps of the First Brigade, National Guard State of New York. He took charge of the Corps a few years ago and had made it into a scientific military organization of very high efficiency. Its excellence was shown at Buffalo during the strikes last summer, when he established a military telegraph service, which was of the greatest service and importance, and for which Capt. Gallup was complimented by the authorities. The corps consists of telegraphers, electricians and engineers. Mr. Edward B. Ives, E.E., was his first lieutenant.

LEGAL NOTES.

INCANDESCENT LAMP LITIGATION.

THE WESTINGHOUSE COMPANY ENJOINED UNDER THE EDISON PATENT.

The hearing on the application of the Edison Electric Light Co. for an injunction restraining the Westinghouse Company from manufacturing incandescent lamps infringing the second claim of the Edison patent, took place before Judges Acheson and Bunnington of the United States Circuit Court at Pittsburgh, December 27. The defendant company filed a general denial of the bill, which claims that the Westinghouse Company is continuing to manufacture and sell infringing lamps.

The court decided to follow the form of the decree of the Circuit Court of New York in the Sawyer-Man case, and an order was so made.

SOCIETY AND CLUB NOTES.

CONNECTICUT ELECTRIC LIGHT ASSOCIATION.

The third annual meeting of the Connecticut Electric Lighting Association, comprising 14 companies, was held at Waterbury, Ct., Wednesday afternoon, Dec. 21. The objects of the association are to promote a better acquaintance and for the discussion of improved methods of electric lighting. These officers were chosen: President, James E. English of the New Haven Electric Lighting Company; first vice-president, James A. Hadley of the Meriden Electric Company; second vice-president, James P. Stow, manager of the Middletown Electric Company; treasurer, John C. English of the Bridgeport Electric Company; secretary, A. M. Young of Waterbury. These officers, with L. C. Whitney of New Britain and Fred Fuessenich of Torrington form the executive committee.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 20, 1892.

Accumulators:—

Storage Battery, G. A. Washburn, Cleveland, O., 488,233 Filed Dec. 10, 1889

Employs perforated metallic electrodes separated by an interposed porous diaphragm and insoluble active material permeated with an electrolytic solution.

Alarms and Signals :—

Railway Signal, E. Schaefer, Lynchburg, Va., 488,225. Filed Aug. 26, 1891.

An automatic electric signal for steam railways.

Signal Repeater, T. H. Patenall, Rahway, N. J., 488,285. Filed Jan. 2, 1892.

Consists of the introduction of an audible signal in connection with the visional repeating signal to warn the operator in case the signal fails to complete its stroke.

Fire Alarm Apparatus, A. G. Davis, Baltimore, Md. 488,388. Filed May 27, 1892.

A mechanism which will indicate by single strokes of a gong the number of the signal box sending the alarm.

Means for Operating Station Indicators, R. B. Ayres, New York, 488,415. Filed Sept. 1, 1892.

Consists of electrical contacts supported by the trolley and a movable spring-restored arm, the depression of which automatically closes the contact.

Distribution :—

Electrical Switchboard, J. W. Lyon, Brooklyn, N. Y., 488,532. Filed June 11, 1889.

Claim 1 follows :

An electrical switchboard composed of cards, each consisting of an insulating material moulded about a series of pairs of contact plates forming a series of sockets.

Electrical Distribution Box, W. H. Hart, Brooklyn, N. Y., 488,198. Filed March 22, 1890.

Employs removable sectional bridging pipes connecting the ends of the ducts entering the opposite sides of the box.

System of Distribution for Polyphase Alternating Currents, C. S. Bradley, Avon, N. Y., 488,307. Filed July 29, 1892.

Has the several wires distributed in pairs among a number of lamp circuits, two or more adjacent circuits including all wires of the polyphase system and motor circuits connected with the wires of the several lamp circuits so as to include all of the polyphase currents in the motor system.

Dynamos and Motors :—

Dynamo Regulator, C. J. Bogue, New York, N. Y., 488,261. Filed Feb. 18, 1892.

Invention consists of pole pieces movable circumferentially relatively to the armature.

Electric Motor, C. S. Bradley, Yonkers, N. Y., 488,305. Filed June 23, 1890.

An alternate current motor whose parts rotate in opposite directions, each provided with a differential phase winding such that a relative shifting of the magnetic poles will be effected upon connection with a circuit supplying differential phase currents.

Alternating Current Motor, C. S. Bradley, Avon, N. Y., 488,306. Filed March 15, 1892.

Claim 1 follows :—

An alternating current motor provided with a self starting and a synchronous winding on its armature, the two being arranged in shunt relation.

Lamps and Appurtenances:—

Lamp Socket and Terminal Therefor, J. Hutchinson, New York, 488,205. Filed Feb. 8, 1892.

Employs an insulating base carrying terminals composed of two pieces adapted to grasp a part of the base and a screw for the purpose of clamping them thereto.

Incandescent Electric Lamp Base, F. C. Rockwell, Hartford, Conn., 488,222. Filed Dec. 26, 1891.

Consists of a bottom formed of a single piece secured to the globe and bearing conducting pieces, and a shell formed of a single piece having two longitudinal chambers with one end closed and the other secured to the bottom with wire perforations through the closed ends.

Process of Uniting Broken Pieces of Arc Light Carbons, N. P. Stevens, Concord, N. H., 488,256. Filed July 1, 1892.

Device for Raising or Lowering Suspended Electric Lights, F. P. Welsh, Omaha, Neb., 488,298. Filed June 14, 1892.

Electric Arc Lamp, A. De Puydt, Liege, Belgium, 488,829. Filed Feb. 17, 1892.

Employs a solenoid in a circuit about the carbons carrying a stationary core and a movable core, the latter suspended from two blade springs and carrying contacts controlling the circuit including the field regulating magnet.

Metal Working :—

Electric Forge, G. D. Burton, Boston, and E. E. Angell, Somerville, Mass., 488,466. Filed Oct. 6, 1891.

A forge for the purpose of uniformly heating metal bars from end to end.

Electric Metal Heating Apparatus, G. D. Burton, Boston, and E. E. Angell, Somerville, Mass., 488,467. Filed Aug. 8, 1892.

Provides a non-heating governor for controlling within certain limits the converted current.

Electric Metal Working Apparatus, G. D. Burton, Boston, and E. E. Angell, Somerville, Mass., 488,468. Filed Aug. 31, 1892.

Provides means for conveniently utilizing one main circuit for different arcs, and automatically regulating the current to conform to the number of such arcs in use.

Electric Metal Heating Apparatus, G. D. Burton, Boston, and E. E. Angell, Somerville, Mass., 488,469. Filed Sept. 22, 1892.

Has for its objects to secure a proper distribution to the working circuits and to avoid sudden shocks or changes of load.

Process of Reducing Franklinite Ores, G. G. Convers, Salisbury, Pa., 488,470. Filed Feb. 29, 1892.

Process consists of rendering the franklinite magnetic, separating it by magnets from the willemite and zincite, and reducing the two last to spelter.

Process of Treating Franklinite and Willemite, G. G. Convers, Salisbury, Pa., 488,471. Filed July 25, 1892.

Similar to 488,470.

Miscellaneous:—

Phonograph, T. A. Edison, Llewellyn Park, N. J., 488,189. Filed May 29, 1888.

Machinery for Setting Up Type, J. Hooker, Beccles, England, 488,265. Filed Nov 23, 1891.

An electric type-setting machine.

Coin Controlled Phonograph, H. Hoeschen, Omaha, Neb., 488,278. Filed Oct. 6, 1890.

Induction Apparatus, C. Willms, Baltimore, Md., 488,299. Filed May 7, 1892.

Employs an automatic circuit breaker, a number of induction coils independently operated and controlled by the circuit breaker.

Phonograph, G. Bettini, New York, 488,379. Filed Jan. 27, 1892.

Phonograph, G. Bettini, New York, 488,380. Filed Mar. 14, 1892.

Phonograph, G. Bettini, New York, 488,381. Filed Mar. 14, 1892.

Safety Attachment for Elevators, L. W. Butler, Brooklyn, N. Y., 488,424. Filed Apr. 8, 1892.

Consists of a pivoted and counterbalanced keeper adapted to engage the rope when the door is opened. and an electrical device for moving the keeper in one direction controlled by the opening and closing of the door.

Musical Instrument, R. W. Pain, New York, 488,482. Filed Dec. 4, 1890.

An electrical keyboard for pianos, organs, etc.

Electrically operated stringed musical instrument, W. H. Gilman, Boston, Mass., 488,520. Filed Mar. 9, 1892.

Railways and Appliances :—

Trolley Stand for Electric Cars, E. M. Bentley, Boston, Mass, 488,179. Filed July 20, 1892.

Comprises an upright cylinder containing a rotatable drum carrying a pivoted trolley pole and a spring plunger sliding in the drum.

Closed Conduit for Electric Railways, L. O. Dion, Natick, Mass., 488,351. Filed Nov. 9, 1891.

Employs a fixed trolley track composed of insulated conducting sections on the roadbed, a vertically movable conducting wire located below and normally out of contact with the track, put having a series of loops and a series of magnets pivoted to fixed supports below the track and provided between their poles with supports of insulating material engaging with the loops of the wire for the purpose of bringing the latter into contact with the track during the passage of the car.

Car Starter, W. Weaver, Westport, 488,462. Filed Oct. 28, 1891.

Employs a rotary motor upon each car, all connected to receive current from the same source, and means upon the locomotive for controlling the current.

Telephones and Apparatus :—

Telephone, P. Rabbidge, Sydney, New South Wales, 486,367. Filed Mar. 3, 1892.

A system of telephony designed for short distances and especially applicable for use in large buildings.

Guard for Telephones, E. B. Chase, Philadelphia. Pa, 488,385. Filed July 30, 1892.

Telephone System, C. C. Jennings, Chicago, Ill., 488,502. Filed Oct. 23, 1888.

Claim 1 follows :

In a telephone system the combination with a series of stations connected with each other by a series of broken double circuits, each of which is closed through one of the two stations connected thereby, a battery and fixed telephone at each of said stations, and electromagnet bells included in the telephone loop circuit of a portable telephone unaccompanied by a battery, adapted and arranged to close any one of said broken circuits at any point intermediate to said stations.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

MR. FREMONT WILSON.

We would invite the attention of electric lighting companies, contractors, architects and others, who are constantly in need of the services of an expert on interior electric lighting and fire insurance matters to the card elsewhere in this issue of Mr. Fremont Wilson, who is already well known in electric lighting circles, and who has in the past four years acquired an enviable reputation as an electric light insurance inspector. He has the confidence of the New York Board of Fire Underwriters, and is also engaged as special inspector for several of the largest companies in this country. He has lately severed all connection with electric lighting companies, and now acts entirely in the capacity of consulting expert to those desiring practical and accurate information on interior work, which he guarantees to pass the inspection of the Underwriters.

He was at one time connected with the Western Union Telegraph Company, but left his position there and worked under Mr. J. H. Vail, chief engineer of the Edison Company, for five years. He was also at one time the sole assistant and right hand man of Mr. F. J. Sprague; and it was under Mr. Wilson's supervision that the original steam and electric plant was installed in this city for the Julien Traction Company. Upon leaving the Julien Company Mr. Wilson became a contractor for interior electric lighting in this city, but determined to give up this branch of the business and enter a field then entirely new in this city, namely that of an insurance expert for electric lighting companies. Mr. Wilson was fortunate enough to be recommended to the local Westinghouse interests in this city as a man of high standing, and became associated with them. He at once commenced an aggressive campaign against poor interior wiring. He is a firm believer of special methods for interior wiring which have been discussed in this journal before, and which are now being adopted in the installing of interior incandescent wires at the World's Fair. During the past three years he has devoted the greater portion of his time to alternating current installations in this city, and the finest, most complete, and safest theatre installations in this country have been installed under his supervision.

His reports on insurance matters are accepted as correct by the leading Boards of Underwriters, and he is authorized to make surveys subject to their authority throughout the entire country. At the time the Subway Commission in this city was first formed, Mr. Wilson was tendered the position of electrician for the Board of Control, but declined its acceptance. A year ago his name was mentioned in connection with a position as chief electrician for the National Board of Fire Underwriters by some of the leading insurance people of this city.

THE WURTS NON-ARCING LIGHTNING ARRESTER.

Elswhere in this issue will be found a most interesting account by Mr. Alex. J. Wurts, on the remarkable action of his non-arcing lightning arrester. In regard to the practical application of this metal to the construction of a non-arcing lightning arrester much can be said in a very few words, and in the simple announcement that out of more than 2,000 non-arcing metal arresters which have been in actual service during the past season on 1,000, 2,000 and 3,000 volt alternating current circuits, not one of them has failed. Such a record as this is truly phenomenal.

To those particularly interested in this subject, the following letters addressed to the Westinghouse Company will probably be more interesting, or at least carry more weight than the mere description of laboratory tests; and Mr. Wagner's letter is worth more than a passing glance in that it illustrates well the satisfactory results obtained by a liberal use of line arresters.

Mr. R. A. Snyder, electrician of the Saratoga Gas and Electric Light Company, of Saratoga, N. Y., writes :—

Gentlemen :—In regard to lightning arresters the "Wurts Arrester" is the best that I have ever seen. My experience with it has been all that could be desired. Since having them on our switchboard we have had three of the most severe thunder showers that I have ever seen and we got our share of the lightning, but the Wurts non-arcing lightning arrester took care of its part of the work to such an extent that it carried 12 or 15 discharges to ground during each shower with scarcely a vibration on the instruments or a strain on the belts, also without blacking arrester to speak of, while an arrester of another make burned out and held arc to ground until we could shut the circuit down.

After my experiences with the Wurts non-arcing arrester, I shall never be satisfied with any other.

Mr. W. H. Blood, Jr., of the Franklin Electric Company, of Kansas City, writes as follows :—

Gentlemen :—Answering your favor of Nov. 2 in regard to our experience with the non-arcing metal lightning arrester would say that we have used several, the worst case being where they were on a 2,000-volt circuit which is connected with a compound machine and although they have passed through many severe lightning storms they were always able to carry off the discharges. They went through some of the severest storms that have ever occurred in this part of the country and many dynamos in the neighborhood were burned out, while those protected by these arresters were unaffected. We do not see how anything could work better than these.

Mr. Herbert A. Wagner, superintendent of the Missouri Electric Light and Power Co., of St. Louis, writes as follows:—

Gentlemen :—I do not wonder that you have difficulty in persuading customers of the practicability of your non-arcing lightning arresters, as at first sight it seems incredible that such a device could work. We have, however, had about 200 of them on our lines for several months, and during all the severe lightning storms of the past spring and summer, we experienced no trouble of any kind on our lines or in our station We have never had a short circuit on our lines during a storm, which would indicate that the arresters promptly broke the arcs as soon as they were formed; neither have we had any arresters burned out or in any way disabled. From my experience with these arresters, I consider them superior to any device which has ever been made before for the purpose, and more simple and effective than I ever imagined a lightning arrester could ever be made. How to prevent the occasional destruction of our converters and switchboard devices by the severe lightning storms which we frequently have here, has been a very great problem for the last two years. From our experience during the past summer, I now think we have the problem solved by the use of a large number of your non-arcing lightning arresters placed at frequent intervals along the lines. We also have a lightning arrester on each circuit where it enters the building, but these are very rarely called into service, as those on the line seem to be sufficient to take care of all discharges. I would be most pleased to recommend your arresters very highly to any one you may refer to me.

F. A. Cheney, general manager of The Elmira Illuminating Company, Elmira, N. Y., writes :—

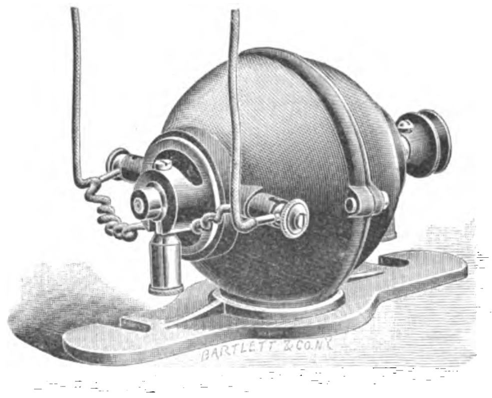
Gentlemen :—In reply to your letter of Nov. 10, regarding lightning arresters, we would say that we have two of the non-arcing arresters in use, and during the past summer these arresters were in operation during six severe thunder showers. Upon one occasion, the lines were struck in three different places ; but notwithstanding this, the arresters took care of the current without the machine tenders knowing anything about it. We found, upon examination, where the current had crossed from bar to bar, leaving scarcely a perceptible mark. We have known positively of nine discharges passing through one of them. To all appearances they are in just the same condition as when erected.

Mr. W. Hoopes, superintendent of the Bala & Merion Electric Company, Cynwyd, Pa., writes :—

Gentlemen :—Your favor of the 11th inst., is at hand, and we would say that we have been using the non-arcing type lightning arrester for several months and consider it successful. Previous to its adoption, we lost one or more transformers during every electrical storm, but since we have distributed the non-arcing arresters liberally over our line, we have not lost a single transformer. We have had some very heavy electrical storms during the past season, and on three occasions, trees have been shattered within a short distance of our lines; each of these occasions was accompanied by a heavy discharge across our station arresters, but no damage was done, so that we have both practical and visual evidence of the value of this sort of protection.

NEW LUNDELL BATTERY MOTOR.

In response to a demand for a small slow speed motor which is adapted for sewing machines and light work of that character, the Interior Conduit & Insulation Company have brought out a small Lundell motor which we illustrate herewith.



BARTLETT & CO. N.Y.

New Lundell Battery Motor.

These motors are wound for both 110 and 4 volt battery circuits and their extremely slow speed,—1,200 revolutions per minute,—their efficiency and torque is said to be remarkable for motors of their size and capacity. They are mounted firmly on a base that may be secured to the floor or any substantial support, and the screw slots in the base provide a ready means for quickly tightening the belt. These motors run absolutely noiseless, are fitted with self-oiling and self-aligning bearings and are neatly finished in black japanning with red and gold striping.

These new motors complete the list of Lundell motors recently placed upon the market by the Interior Conduit & Insulation Company, from $\frac{1}{16}$ to 5 h. p. capacity. The above small motors are used exclusively by the Automaton Piano Company, for operating the mechanism of their automatic piano.

The electrical engineer of a western construction company in sending us some information writes: "You will find my name on your books, and I don't think it will be taken off as long as the money gives me such fine returns. I would not be without your paper on my desk."

A NEW GENERAL ELECTRIC SWITCHBOARD.

ONE of the handsomest and largest switchboards in the world, has just been completed at the Schenectady Works of the General Electric Company for the first station of the Edison Electric Light and Power Company of San Francisco, and is shown in Fig. 1 of the accompanying illustration. It is constructed of slabs of highly polished white Italian marble mounted on an iron frame, and is 56 feet 8 inches in length. The board provides for the distribution of 2,200 kilowatts, or 14,666 amperes at 150 volts, from twelve generators of the General Electric Company's multipolar type coupled directly to triple expansion engines. Ten of these dynamos are of 200 kilowatt; two are of 100 kilowatt capacity, and all are arranged on the three wire system. The main and auxiliary busbars run the entire length of the switchboard and are set in a rack in the rear. They are so arranged that they can be cut in two at the centre by means of heavy switches on the face of the board. This allows the operation of the station under four different potentials at the same time. Provision is made for twenty-four feeders, each equipped with two ampere meters and three switches. Each switch has two blades, one for the main and one for the auxiliary bus, the positive and negative switches of each set being provided with safety catches.

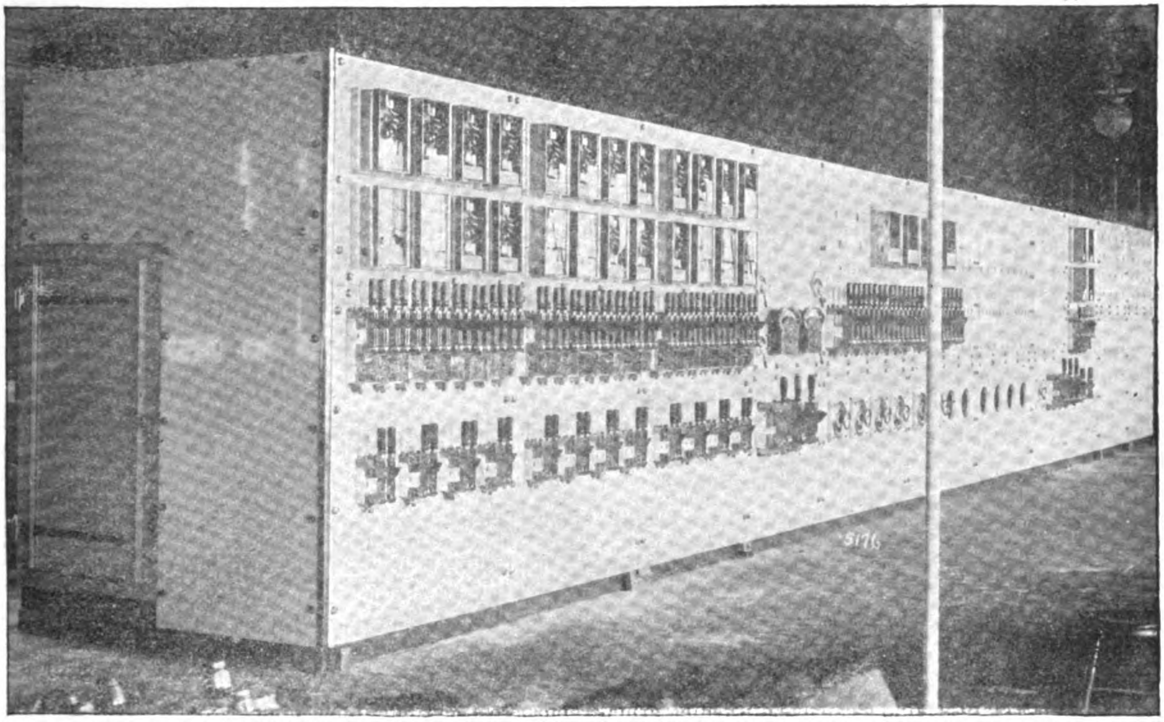


FIG. 1.—SWITCHBOARD FOR THE EDISON ELECTRIC LIGHT AND POWER CO., SAN FRANCISCO, CAL.

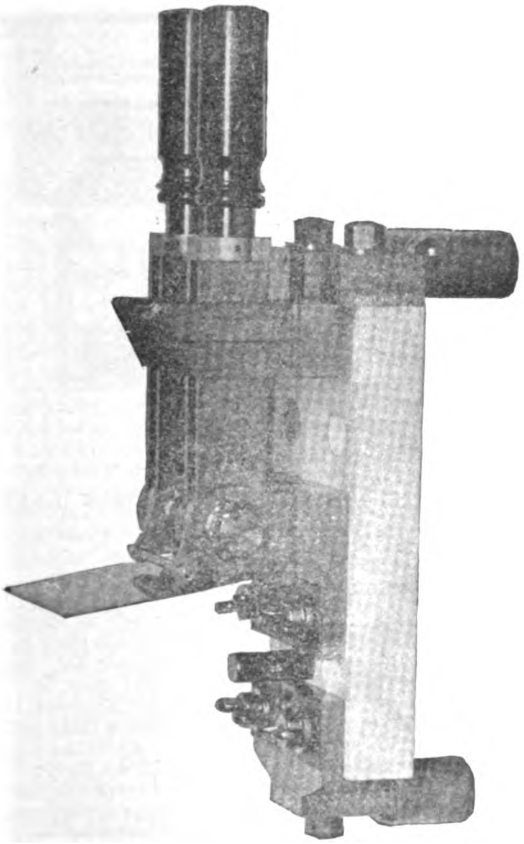

FIG. 2.—IMPROVED STATION SWITCH.

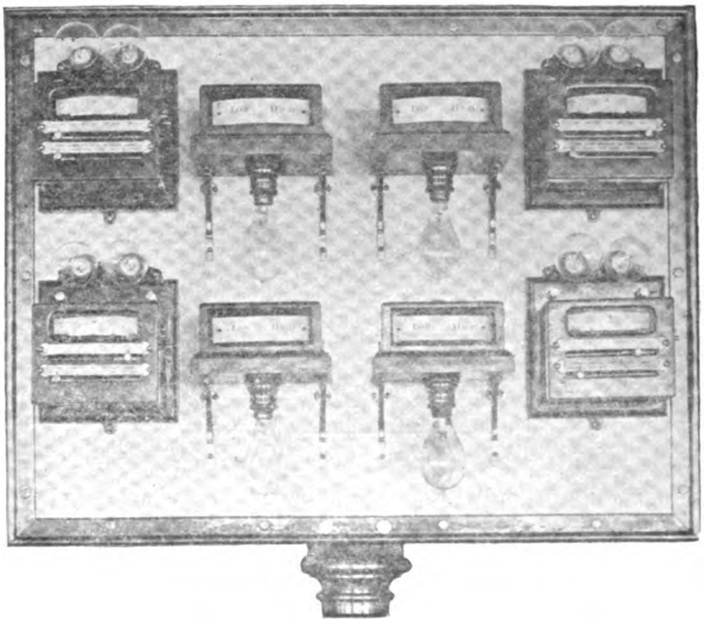

FIG. 3.—PRESSURE INDICATORS AND GALVANOMETER.

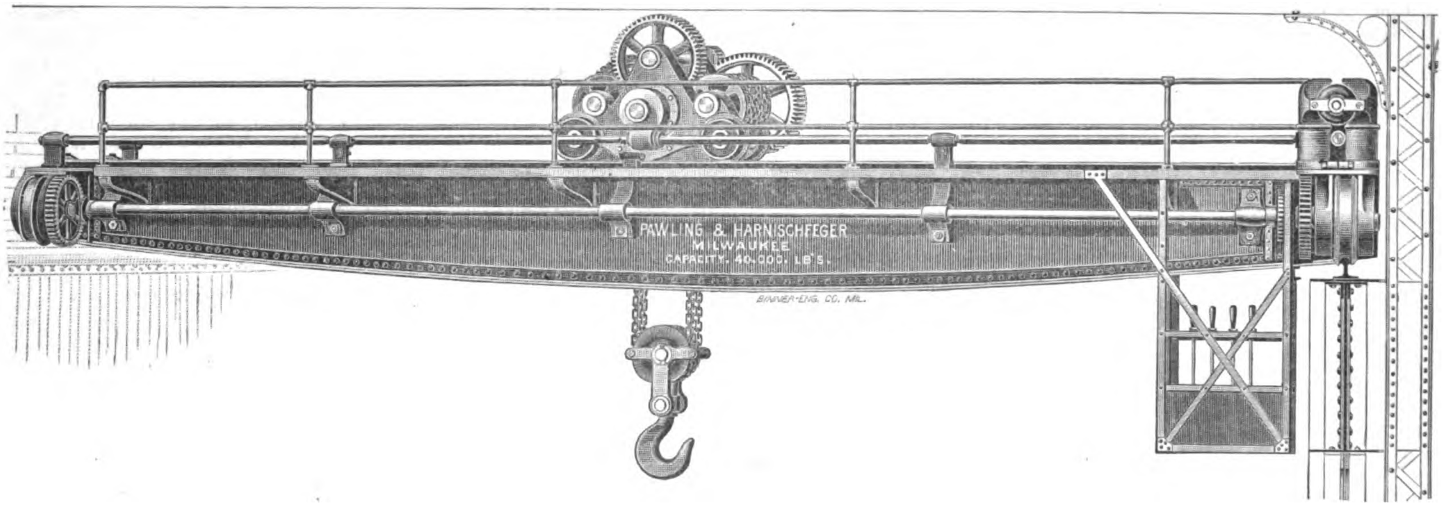
A novel feature in these last named switches, Fig. 2, is the mica covering for the fuse, which is hinged and can thus be readily raised where necessary for the insertion or adjustment of the fuse. A special thirty-point indicator switch is mounted on the board by means of which it is possible to read in the station the voltage at all the feeding points in the outside system. Each dynamo is provided with an ampere meter, a dynamo field regulator and two switches, each double-bladed, so that the dynamo may be thrown upon either the main or auxiliary bus bar. The ampere motors are mounted on bases of marble similar to that of the board, and have highly finished brass covers with fronts of bevelled heavy plate glass. The regulators are also fitted with white marble tops. Beside the apparatus already mentioned, the board is equipped with the necessary pressure and galvanometer switches. Two ornamental pillars supporting small auxiliary boards, are to be erected at either end of the board. Upon these will be placed the dynamo galvanometers and pressure indicators, Fig. 3. All connections are ma de at the back of the switchboard. Those between the instruments and the bus bars are through flexible copper cable of 1,500,000 circ. mills cross section.

The board is built up of 26 marble slabs, each of about 25 square feet of surface, and weighing in the aggregate over seven and a half tons. The weight of the main switchboard complete and fitted for the present requirements of the station, is 37,000 lbs. 5,000 lbs. of copper connecting cables, 6,000 lbs. of copper bus bar, and 10,000 lbs. of high conductivity metal were used in its construction. Each dynamo switch of 1,500 ampere capacity weighs 150 lbs., each double-blade feeder switch 100 lbs., and the large bus bar switch 200 lbs.

Fig. 1 shows the switchboard as it stood in the factory a short time before completion. When erected in its place in the station at San Francisco, it will be further adorned by the addition of an ornamental cornice and base board.

THE PAWLING & HARNISCHFEGER ELECTRIC CRANES.

Messrs. Pawling & Harnischfeger, of Milwaukee, Wis., who make a specialty of heavy machine tools, are now constructing for the Siemens & Halske Electric Co. of America, three large lathes which will be placed in the large works now being erected in Chicago. One of these lathes will be capable of turning armatures sixteen feet in diameter, and the other two will have ten foot swing.



PAWLING & HARNISCHFEGER
MILWAUKEE
CAPACITY. 40,000. LB'S.
BINNER-ENG. CO. MIL.

Electric Crane, Siemens & Halske Shops, Chicago.

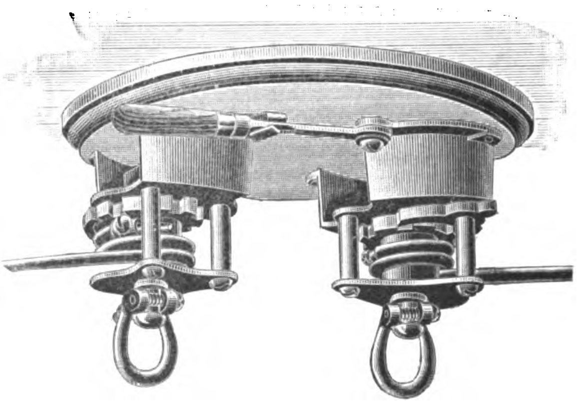
This firm also build electric cranes adapted for foundry use, traveling cranes, one type of which, designed to lift 20 tons, is shown in the accompanying engraving.

Messrs. Pawling & Harnischfeger have now under way a 15-ton electric crane for the Weisel & Vilter Manufacturing Co., and a 6-ton crane for Greenslade Bros., of Milwaukee.

PFLUGER'S LINEMAN'S DELIGHT.

In lining up a building for an arc circuit, the wire should be taut, straight and without sag. To accomplish this, insulators must be screwed to the ceiling at different intervals between ceiling boards, to keep the wire from sagging. These insulators not only disfigure and ruin the ceiling, but are in many instances the cause for grounds in the circuit.

To obtain a perfectly straight and taut line wire, the lineman has considerable trouble and has to use different tools such as come-alongs, tackles, pulleys, etc. The proper results can be obtained more cheaply and readily by using the ceiling board called "The Lineman's Delight." A glance will show the working of it. Place the ceiling boards in their proper positions, where lamps are required and cut off pieces of wire reaching from one ceiling board to the following one, being careful not to cut them off too short. Then fasten both ends of the wire in the revolving binding posts of the two different ceiling boards and wind those binding posts up with a wrench till the wire is straight and taut. The dogs engaging the ratchet will prevent the unwinding of the wire.



Pfluger's "Lineman's Delight."

The lamps are hung in the usual way to the ceiling board. Each ceiling board is provided with a switch to take the lamps out of the circuit when it becomes necessary. The advantages of the ceiling board are very easily seen; first, in obtaining a perfectly straight and taut circuit without any insulators; second, in saving a great deal of time in the construction, and therefore considerable expense; third, all kinds of wire, no matter how crooked, can be used; fourth, the wire can be removed instantly for the purpose of cleaning the ceiling, without any damage to the wire and board; fifth, any person can handle it. The ceiling board is secured by letters patent. It was invented and is manufactured by Chas. A. Pfluger, 313–317 S. Canal St. and 1762 N. Halsted St., Chicago, Ill.

RIES ISOLATED PLANTS.

The Ries Electric Specialty Company are at present installing quite a number of isolated plants, in which they employ a low tension alternating current dynamo, feeding the lamps directly without the use of converters. This plan they find highly satisfactory, as the converter losses are entirely avoided and the system permits the use of their regulating socket, thus affording the consumer the advantages of a safe and controllable light. In stations where converters must be used, Mr. Ries believes it would be far better to use a small number of large converters, each capable of feeding a number of houses from a common secondary circuit, than to use a large number of small converter units, as is now the general practice. Of course such large units could only be advantageously used where the houses requiring the light are situated closely together. The Ries Electric Specialty Company, have never found any trouble, however, where the isolated plants referred to have been installed.

MR. H. T. PORTER.

AN annoying mistake was made in the advertising columns of THE ELECTRICAL ENGINEER of December 28. Instructions were received from the Buckeye Engine Company to insert the name of H. T. Porter as the New York representative of that Company. This insertion, however, was made in the advertisement immediately under that of the Buckeye Engine Company—the card of the John T. Noye Manufacturing Company, which made it appear that Mr. Porter was to take charge of the New York office of the Noye Company, Mr. Copeland's address being omitted. The mistake was purely a mechanical one, and the many friends of Mr. C. H. W. Copeland will be glad to learn that he still continues in charge of the New York office of the John T. Noye Manufacturing Company at his old stand, 186 Liberty street.

TAKING A WHOLE BUILDING NOW.

F. P. LITTLE & Co , of Buffalo, will shortly remove from 141 to 135 East Seneca street, where they will occupy the whole building. The growth of their business is so large and steady as to require the additional facilities at once.

NEW ENGLAND NOTES

CUMNER, CRAIG & COMPANY, of Boston, is the name of a new firm recently started in the general electrical engineering and supply business, with headquarters at No. 509 John Hancock Building, Boston. Mr. Arthur B. Cumner has been for the past year connected with the Holtzer-Cabot Electric Company, and is a student of the Institute of Technology. He has a wide acquaintance among influential men in the city of Boston. Mr. J. Hally Craig has had years of experience in the electrical business both in this country and in England, and has been for the past two years connected with the Holtzer-Cabot Electric Company in various capacities. Mr. Craig is well known to electrical men in New England and elsewhere, and the new firm will doubtless soon become prominent in this vicinity.

THE BROWN ELECTRIC COMPANY, of Boston, has completed its organization, and will be all ready to commence business in its new and well appointed store on the corner of Summer and Federal streets. Mr. Maybin W. Brown, who is already well known to the electrical trade, will take the general managership of the company, and his numerous friends will be pleased to see him once more at the head of a good company. The Brown Electric Company will handle a general line of electric light, railway and power supplies, and will have exclusive territorial agencies of many well known and popular electrical goods. The location of the store is a good one, and the company are looking forward to a good business on the start of the New Year.

THE DAVIS ELECTRICAL WORKS, of Springfield, besides doing a successful business in the manufacture of incandescent lamps, have already achieved a marked degree of success in their comparatively new field of repairing burned out incandescent lamps. This company have a splendidly equipped factory in Springfield, thoroughly adapted for the work. They will take burned out lamps, open the bulbs, put in new filaments, seal them up and return them to the consumer in as good a condition as, if not better than, when new. Every consumer of incandescent lights should investigate this plan of repairs, as it is claimed that considerable saving can be made.

THE MASSACHUSETTS CHEMICAL COMPANY are in receipt of many of the strongest kind of testimonials in favor of their Insullac for armature and other electrical insulation. It seems to have filled a felt want, and as it can be used on armatures without baking, it saves a large amount of time, labor and expense. One of their most recent testimonials from the West End Street Railway Company, of Boston, who are using it exclusively for their motor armatures, is well worth reading, and will be found printed in full on page 15 of the advertising matter in this issue.

THE BOSTON ELECTRIC LIGHT COMPANY, have completed their plans for a new station in South Boston. The station will have a capacity at present for 1,000 h. p., though the general plan allows for an increase up to 2,000 h. p. The station is being built primarily for the accomodation of South Boston, though circuits will be run to Matapan and Roxbury districts, and will include arc, incandescent and power apparatus. All modern improvements will be adopted, such as mechanical stokers, coal conveying apparatus, slate switchboards, traveling cranes: and everything done to make this a model station in every respect.

MR. H. H. BROOKS, of the American Circular Loom Company has just returned from a two months trip to the Pacific coast in the interests of his company. The outlook for a large business in their specialties of wire and conduit is extremely good, and Mr. Brooks is already devoting his attention to the increase of their facilities for manufacture.

MR. C. O. BAKER, of Newark, was in Boston last week, presumably to sell platinum. Report has it, however, that he was seen, in company with a number of other well-known electrical gentlemen, in the vicinity of the Sheriff's office, and afterwards capably filling the position of an expert appraiser of certain electrical goods. Mr. Baker has reason to be proud of himself in his new rôle of electrical expert and appraiser. It is really a pity that he has such large interests in the platinum industry.

THE GIANT ELECTRIC MOTOR COMPANY, of Portland, Me., have recently closed a contract with the Manchester House, of Manchester, N. H., for an isolated electric lighting plant, and also recently closed a contract with the town of Phillips, Me., for the town electric lighting plant. The Giant Company have several other plants under consideration, and are at present making arrangements for doing the heaviest kind of electrical work, and in largely increasing their manufacturing facilities.

L. DION, of Natick, Mass., has disposed of his invention of a closed conduit system for propelling electric street cars, to a Boston syndicate, of which Mr. Oliver Ames, of Boston, is president, and Col. Levi R. Greene is general manager. The drawings for a working model are being pushed to completion, and it is proposed to demonstrate the value of the invention on a short section of track, as soon as the model is built and arrangements can be made.

THE CAMPBELL ELECTRICAL SUPPLY COMPANY, of Boston, are following up their previous announcement of the manufacture of "Century" wires and cables, with a neat price list, which gives details of their various manufactures in wires, cables, tapes, insulating paints, and belt dressing. They also call attention to their anti-induction telephone wire, and to the "National Shielded" wire, which is made for places where excessive abrasion is met with.

MR. HENRY F. KELLOGG has been appointed manager of the new municipal electric light plant for the town of Wellesley, Mass., which has recently been put in operation. Mr. Kellogg will still retain, however, his business connection with the Whitney Electrical Instrument Company, of Boston.

PETTINGELL, ANDREWS & CO., 190-202 Summer street, Boston, have issued a very neat calendar for 1893, with an engraved study after Rosa Bonheur at the top. It is intended to advertise their electric railway and electric light supplies, and will accomplish its purpose very effectually.

THE WALWORTH MANUFACTURING COMPANY, of Boston, are in receipt of orders from the Thomson-Houston International Company for two car loads of their well known street railway poles for Rio Janiero, one car load for Mexico, and one car load for the West Indies.

PHILADELPHIA NOTES.

THE PENNSYLVANIA ELECTRIC ENGINEERING COMPANY has contracted to place in the Commonwealth Hotel, Harrisburg, two multipolar National incandescent dynamos, one of 700 the other of 350 lights. They are also placing 55 1,200 c. p. arc lamps, one National dynamo and five miles of construction work for the Steelton Light & Power Company, Steelton, Pa.

THE PARTRICK & CARTER COMPANY will soon bring out a simplified "Return Call and Fire Alarm System" which will be low in cost and thoroughly efficient in its workings. They will also begin the delivery of their new automatic annunciator early in January. Orders are already booked for them far in excess of their anticipation.

MR. T. L. TOWNSEND, of the Partrick & Carter Company, has just returned from a three months' trip through the South. He is a quiet young man but his order books are eloquence itself.

WESTERN NOTES.

THE RACINE HARDWARE MFG. CO., of Racine, Wis., have been awarded the contract for building twenty-five electric launches for the World's Columbian Exposition. These boats are 34 feet long by 6 feet beam and are to be fitted up in the latest improved manner, with decking and interior finish of mahogany, canopy top and all modern appliances. These boats are for use on the lagoons, to carry the World's Fair visitors, and are to be completed by May next.

THE LUNKENHEIMER Co , of Cincinnati, have doubled their capital to $500,000, so as to meet the demand for the celebrated Lunkenheimer brass and iron specialties. The business will now be carried on under the above name, with E. H. Lunkenheimer, as president; C. F. Lunkenheimer, as vice president, and D. T. Williams as secretary

WESTERN NOTES.

Mr. Leslie W. Collins, who for some time past has been the New York representative of **The Electrical Engineer**, has been transferred to Chicago, where he has already assumed the duties of Western Editor and Manager, with large and commodious offices in the Rookery. Mr. Collins is so well known and popular in the West that he needs no introduction.

World's Fair Notes.—The mechanical and electrical engineering section of the construction department, which is in charge of Mr. Frederick Sargent, have removed from their old quarters in the Construction Building in the Fair grounds at Jackson Park to a new building built especially for them in the rear of Machinery Hall, where they will remain during the entire period of the Exposition. The new offices are very handsomely and conveniently fitted up, private rooms being prepared for each of the staff. The incandescent lighting in this building is being furnished from one of the old-time Edison dynamos of the "L" type, which is quite a curiosity in its way but does excellent work. This, together with a 50 light Standard dynamo built by the Standard Electric Co., of Chicago, forms a small additional temporary plant which is located in the Machinery Hall annex, these two machines being driven by a Ball & Wood engine. As soon as the Westinghouse Co. are ready to furnish current, they will take over the incandescent lighting in this building.

The New York Insulated Wire Co. are making good progress with the wiring of the World's Fair buildings. All the State buildings and the Administration Building are practically completed and work has now been commenced on the Women's Building. The work in the Administration Building is being pushed with the utmost despatch in order to enable the offices of the Director-General and heads of departments now in the Rand-Mc Nally Building to be moved there, where they will go immediately the Westinghouse Co. have their lights running there for them. They will probably move in about this time. This will bring all the departments of the Exposition on the grounds at Jackson Park in the most favorable position for rapidly completing the work at the Fair. The Worthington Co. are busy on the immense pump station which they are building in the grounds.

The Railway Equipment Company are handling a voluminous business in the Ahearn electric heating devices for the manufacture of which they some time ago equipped a very complete factory. The orders have come in so rapidly from all parts of the country that they have had hard work to keep up with them, but with increased facilities hope to be able to do so very shortly. Mr. W. R. Mason, the president of the company, reports great activity in the electric railway supplies manufactured and handled by his company. The new line of overhead devices recently placed on the market are having a very large sale.

Taylor, Goodhue & Ames, Monadnock Building, Chicago, are doing a brisk trade and getting hold of an exceedingly fine line of new and valuable specialties. The "Diamond" converter, the agency for which they recently secured is proving a rapid seller and its good features are being duly appreciated. The Standard Electric Company are very busy turning out their arc machines and lamps, they have recently secured several large contracts for their deservedly popular system.

Mr. Albert Blanchard, 427 Rookery, Chicago, has furnished quite a number of power plants with the complete combustion down-draft boilers for which he is agent in the west. Mr. Blanchard states that they are a positive panacea. He contracts to build complete power plants for electric lighting, railway or other work and his extended experience in this line insures the erection of an economical and reliable plant.

The Electric Appliance Company report large sales of their new Acme wire guards. They are placing large numbers of them with eastern and western jobbers as well as supplying them to large users all over the country. They report that the new Whitney instruments for alternating currents will be ready for the market very shortly as well as a line of cheap switchboard instruments.

The Mosher Electric Company, 137 Ontario street, Chicago, have received a large number of orders for their arc lamps for direct and alternating incandescent circuits. They are turning them out as rapidly as possible and have increased their facilities considerably to take care of the growing business. They state that their lamps are giving excellent satisfaction and that users are well pleased with them.

The Enterprise Electric Company are now settled in their new quarters, 307 Dearborn street, and are ready to take care of any amount of business with their increased floor space and facilities. All lines of trade are good, especially in National India Rubber wire. They expect to put in the market some new and meritorious specialties the first of the year.

Mr. Leo Daft, who is so widely known as one of the early pioneers in electrical engineering, he being one of the first to advocate and introduce electrical transmission of power in this country, spent several days in Chicago last week, buying machinery. Mr. Daft then went east where he will visit the principal large cities.

The Post-Boynton Strong Company, 413 Home Insurance Building, make a specialty of the manufacture of battery zincs. They are casting a large amount of metal for this purpose right along, and they guarantee their zinc to be of the highest obtainable purity.

Wm. Hood & Co., managers of the Chicago office of the Electric Manufacturing Co., Oconto, Wis., are filling orders for Brilliant lamps which continue to flow in upon them. They make many strong claims for their lamps and their factory is kept busy.

Mr. A. M. Walter, who has a large acquaintance in electrical circles in Chicago and the west is spending a short vacation here. Mr. Walter is now connected with the General Electric Company in their factory at Lynn.

Mr. F. Bathurst, of the Schenectady Works of the General Electric Company, was among the visitors to the World's Fair city last week.

NEW YORK NOTES.

Goubert Feed Water Heaters. Among recent sales of the Goubert Manufacturing Company, 32 Cortlandt street, New York, —sole makers of the Goubert feed water heater—we notice the following: Negaunee and Ishpeming Street Railway and Electric Company, Negaunee, Mich., 350 h. p.; Urbana and Champaign Electric and Street Railway Company, Champaign, Ill.. 600 h. p.; Mutual Light and Power Company, Montgomery, Ala., 700 h. p., Edison Electric Illuminating Company, of New York, 2,000 h. p.; Edison Electric Illuminating Company, of Brooklyn, N. Y., 1,000 h. p.; West Side Street Railroad Company, Elmira, N. Y., 400 h. p.

Mr. J. Stanford Brown, E.E., has resigned his position as resident engineer of the Camden Horse Railroad Company, Camden, N. J., to take effect at the end of December. This move will not sever his present cordial relations with the company as he is retained by them as consulting and supervising engineer. With the new year Mr. Brown becomes consulting and constructing engineer to the Neftel & Marsh Company of 136 Liberty St., New York, and will thereafter again make his home in this city.

Mr. William Wright has resigned from the Wright Universal Electric Company, of 26 Whitehall street, this city.

CANADIAN NOTES.

Mr. Charles F. Medbury, formerly with the Thomson-Houston Company, Boston, Mass., has been appointed agent of the Canadian General Electric Company for the Montreal district.

The Royal Electric Company of Montreal has been awarded by the Montreal City Council the contract for lighting that city for a period of ten years from the expiration on January 1st, 1894, of the present contract of this company with the city, at the following yearly rates:

1st. term of	5 years.....	$124.10 per light.....	.34 cents per night
2d. "	" 3 "	120 45 " "	.33 " " "
3d. "	" 2 " ...	116.80 " "	.32 " " "

There are 2,000 c. p. arc lights burning all night, for which the price by the unexpired contract is $146. There are now in use for lighting the city 915 arc lights and 360 incandescent lights of 32 c. p. each, besides some 700 gas lights.

The Automatic Telephone and Electric Company, of Canada, has been organized with a capital of $250,000, and has purchased the Canadian patents of Mr. A. B. Strowger for his automatic telephone exchange system, which dispenses with the central operator. The object of the company, whose head office is at Montreal, is to introduce this system throughout Canada, and also to manufacture the apparatus as well as fit up and equip telephone exchanges. At a recent meeting, Mr. J. P. Dawes was elected president, Mr. H. M. Linnell, formerly with the Edison Company, managing director, and Mr. J. A. Culverwell, general agent.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

Electrical Engineer.

VOL. XV. JANUARY 11, 1893. No. 245.

LAMINATED OR DIVIDED IRON AND OTHER METALLIC MASSES IN ELECTROMAGNETIC APPARATUS.—II.

BY

Thos. D. Lockwood

Charles Grafton Page.
(From *Scribner's Magazine.*)

THE three names most prominent in connection with the earliest instances of adoption of divided iron cores are those of Sturgeon, Bachhoffner and Page. So far as I can ascertain, William Sturgeon was the first to publish an account of the benefits to be derived from dividing the iron of an induction coil core. His announcement was made in a paper read before the Electrical Society of London, August 5, 1837, which paper is published in *Sturgeon's Annals*, (Vol. i. pp. 470–484.)

In Sturgeon's experiments, he made an electromagnet with a core formed first, of a cylindrical roll of sheet tin; and second, of a bundle of iron wires. In this connection he remarks that a Mr. Payne had tried the magnetic effects of a bundle of iron wire in an electromagnetic helix. This, it is evident, concerns merely the core of an electromagnet, and the effect upon its attractive power of dividing the same.

These experiments, however, led Sturgeon, as recorded in the same paper, to try divided cores in his induction coil, and he goes on to tell us how first he tried a solid iron core with advantage, but that he found the advantage to disappear as he increased the speed of his circuit breaker, and that he then successively tried iron tubes, cylindrical rolls of sheet tin, a bundle of thin iron wires, and bundles of narrow strips of tin plates (true laminations); with the result that the sparks were much brighter and the shocks much greater; and this with a much higher speed of the circuit breaker. He then discusses the philosophy of these phenomena, and ascribes them to magnetic inertia.

Sturgeon adds a footnote to this paper, to the effect that about a fortnight before the reading of the paper, he had lent Bachhoffner one of his coils, and that he, without knowing anything of Sturgeon's experiments, had independently discovered that a bundle of iron wires in the axis of the helix caused it to give a better shock than when a solid bar was employed; and on page 496 of the same volume is found a letter from Bachhoffner describing the mechanism he employed, and accentuating the statement that *the iron wires of his* core were insulated. We find (*Annals*, Vol. ii, p. 73) that the same gentleman read a paper before the Electrical Society of London, Oct. 23, 1837, which remarked that in a former paper he had stated that the insertion of a bundle of wires in the axis of the coil increased its power twofold; he would now say twenty fold.

In a letter dated Feb. 10, 1838, (*Sturgeon's Annals*, Vol. ii, p. 203), one J. C. Nesbit, describes an induction coil built upon the lines laid down by Sturgeon, and says that he has "a bundle of very thin iron wire in the axis of the bobbin."

Only a few days later, Prof. G. H. Bachhoffner, again has a paper, (*Annals*, Vol. ii, p. 207), written apparently in confutation of a paper read by Dr. Golding Bird, in which reference appears to have been made to the merits of a divided core, without giving credit to Bachhoffner for such a core. In this paper Bachhoffner substantially asserts himself to be the originator of the idea. He refers to a statement made by Golding Bird that the effects of induced currents were "considerably augmented when the bundle of insulated iron wires was employed in lieu of the bar of iron," and states (p. 213) that he (Bachhoffner) has "invariably employed the bundle of insulated iron wires." He also points out that to surround the wires by a scroll of tinned iron practically converts them into a bar, and is of no use.

These gentlemen all appear to have experimented first, and reasoned later. Professor Charles Grafton Page to whom we must now refer, seems to have reasoned the matter out first, and then to have proved the correctness of his reasonings by experimentation. He records his work in *Silliman's Journal* (Vol. xxxiv, No. 1, p. 167, July, 1838), and (Vol. xxxv, 1839), the latter paper being dated at Washington, Nov. 13, 1838.

In his "History of Induction," published in Washington, 1867, which I have closely examined, he refers to these papers, which also appear in abstract form in *Sturgeon's Annals*, (Vol. iii, pp. 389–393, and pp. 478–486). None reading these papers can fail to be impressed with the idea, that the part borne by Page in the investigations which produced the modern induction coil, was of the highest consequence. He calls his induction coil, a compound magnet. He tells us that he removed the bar of iron from the coil, and in its place introduced a bundle of annealed iron wire, which magnified the sparks and shocks surprisingly. He then successively substituted a bundle of smaller wires, and a bundle made of *seven pieces of hoop iron*, which latter he found to produce very powerful effects. In discussing these phenomena, he says; "When the battery is withdrawn, there is not magnetism enough retained to affect a very delicate needle. From this perfect neutralization of power arises in great measure the intensity of the secondary current. The neutrality is partly due to the reduced size of the bars, but chiefly to the action of their similar poles upon each other, when the exciting cause is withdrawn."

He notes in his second memoir that steel, when divided, answers very well for cores, and accounts for this also, by the above theory of polar re-action; and finally considers the action of closed circuits in the metal associated with coils, such as tubes between the two coils or between coils and cores, showing their dulling effect; and points out that in view of such action, metal bobbins, or bobbins having metal cheeks, should not be used. Much of Page's work is recounted by himself in his little book "The History of Induction," published in Washington in 1867.

Here, so far as divided cores are concerned, Page claims for himself independent invention, but nothing more; and states that the discovery with him "was the result of a process of inductive reasoning" as related by him in *Silliman's Journal* (Vol. xxxiv, No. 1, p. 167, for July, 1838). He also refers (p. 29) to the same article of Golding Bird, which excited the ire of Bachhoffner, as having appeared in the January number of the London and Edinburgh *Phil. Mag.* 1838, (Vol. xii, p. 18); and referring to the circuit breaker there described, mentions that Bird states in his article that he thought it was his own, but that on the arrival of the October number of *Silliman's Journal* for 1837, he had found himself anticipated and that the merit of "originality" belonged to Dr. Page.

Before dismissing Page, we must refer to the fact that he, being employed in the Patent Office, could not when he was ready so to do, take a patent for such features of the induction coil as he considered were justly his own invention; but that in 1868, by special act of Congress he was permitted to take out a patent, which was granted April 14, 1868, (No. 76654), and which was re-issued with additional claims, October 10, 1871 (No. 4588). This was the celebrated Page patent which was sustained by Judge Blatchford in 1879. In its specification, the iron core made of a bundle of plates or wires is shown and described, and its effect stated; Fig. 1 of this paper is a copy of the patent office drawing of this core, and shows four forms which we may call A, B, C and D.

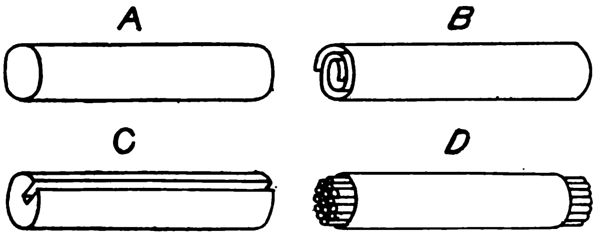

Fig. 1.

Prof. Page in his specification says the core "is composed of a bundle of soft iron wires, separated from the primary coil by a layer of some insulating material. If the wires are clean and bright, it is best to varnish them." He says further on: "Instead of a bundle of iron wires placed in the axis of the coil, the magnet may consist of thin plates, as shown in Fig. 1 A, and the plates may be made to adhere by varnish between them; or a piece of thin sheet iron rolled up into a scroll, as shown in Fig. 1 B, may be used, the surface of the iron being covered with varnish. Or a bar of iron divided by a longitudinal furrow or groove down to its axis as shown in Fig. 1 C may be used. The bundle of wires is, however, the preferable form, as shown in Fig. 1 D, the bundle or fasciculus, as it is sometimes called, being bound or wrapped with some non-conducting material."

I do not see that Page in his patent describes anything in advance of what he might justly found upon his early communications to *Silliman's Journal*, and it is most interesting to note that at this time he had fully recognized the identity in principle between cores made of wires, cores made of plates, and solid but grooved cores; and that he also had recognized the necessity of insulating the individual elements of a divided core from one another.

From a consideration of the record, it appears to me that Sturgeon was first in the idea of dividing the iron of cores, and first also in publication; that Bachhoffner was a close second, both in performance and publication, and also the first to observe the utility of insulating the wires; and that Page was third in performance and publication, second in noticing the importance of insulation, and an easy first in his reasonings upon the subject; and independent and original in every point.

In the Southern States during 1892, no fewer than 102 electric light companies were formed.

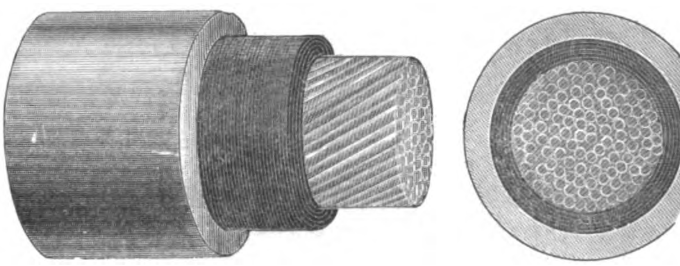
NEW YORK'S ELECTRICAL SUBWAYS.—II.

BY

Wm Maver Jr.

VII.—CABLES EMPLOYED IN THE SUBWAYS.

The cables employed by the Telephone company are chiefly of the lead encased fibrous type—namely the Paterson; also a paper cable.[1] The telegraph companies also use cables of the fibrous type, The Standard Underground, Paterson, etc., but they also employ many rubber compound cables, such as the Kerite, Okonite, Safety, etc.

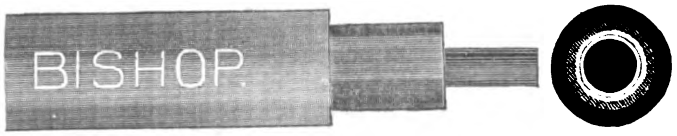


Eigs. 7 and 8.—Standard Underground Cable.

The cables used in the electric light service, exclusive of the "Edison," are of two general types, namely fibrous and rubber compounds; both of which are lead covered. Fibrous cables are, of course, lead encased to exclude moisture. Rubber cables were primarily lead encased to prevent the ill effects of gases, acids, etc., upon them. They would most likely now, if for no other reason, be lead encased to prevent the deterioration which it is well known occurs when vulcanized rubber is freely exposed.

The size of the electric light conductors employed in the subways varies with the requirements, from No. 000,000 to No. 10 B. & S. The thickness of the insulating wall of the cables varies with the type of cable employed and also with the electrical pressure which the insulation is expected to withstand, being as a rule somewhat thicker in the case of fibrous cables than in that of the rubber compound cables.

Of the fibrous cables in operation in the subways in the electric light service, by far the largest amount has been manufactured by The Standard Underground Cable Company,—approximately 290 miles. There are a few miles of a paper cable known as the Norwich, employed in this service. In this cable the paper is laid over the conductor in strips, spirally, to a thickness of about .175 inch; the paper having previously been saturated with a resinous solution.

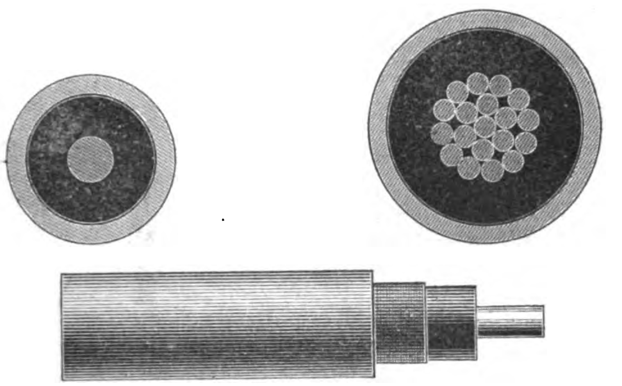


Figs. 9 and 10.—Bishop White Core Cable.

Of the rubber compound cables in the electric light subways the bulk is manufactured by the Safety Insulated Wire and Cable Company, of whose product there are in use about 280 miles. This cable is known as a seamless cable, the rubber compound, while in a plastic state, being pressed on to the conductor while passing through a suitable die. The rubber compound is placed in a chamber which is kept, by suitable means, at a desired temperature. Mechanism within the chamber gives the plastic compound a tendency towards the die. The wire passes, from a reel, through the chamber, and in passing out is held accurately in the centre of the die, which insures an even distribution of the compound around the wire. The wire is then drawn slowly over a long table to a large reel, after which it is placed in the vulcanizing chamber.

---

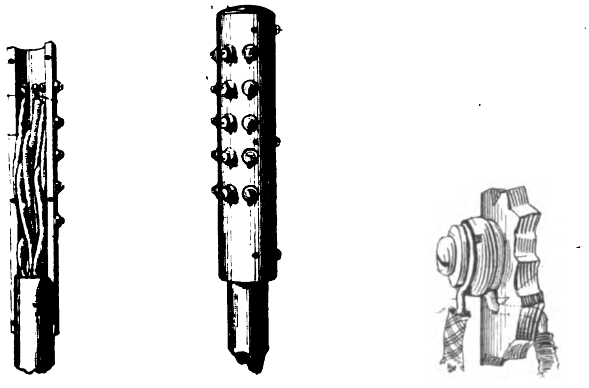
[1] See "Recent Improvements in Telephone Engineering, by H. L. Webb," in The Electrical Engineer, Sept. 7, 1892.



Figs. 11, 12 and 13.

There are also in use in the electric light subways about 25 miles of the well-known white core rubber cable manufactured by the Bishop Gutta Percha Company; also about 20 miles of Cobb cable and a few miles each of Okonite and Simplex rubber cable.

Several of the above mentioned cables are shown in section and cross-section in the accompanying figures. Figs. 7 and 8 represent an electric light cable (stranded conductor), cross-section and lengthwise, of the Standard Underground Cable Company's manufacture. The lead casing, the insulating material, and the conductor are clearly defined. Figs. 9 and 10 illustrate a section and cross-section of the Bishop white core cable, solid conductor. Figs. 10 and 11 represent cross-sections of the Safety seamless cable. Figs. 11 and 12 show the exact size of the conductor, (solid and stranded) and the thickness of the insulating wall and lead casing of a No. 2 B. & S. and No. 0000 B. & S. conductor, respectively. Fig. 13 represents a section of the same cable. In Figs. 11, 12, 13 also the tape which is wound over the insulation is indicated. This taping is found serviceable in protecting the rubber insulation from injury when the lead covering is being put on and when the latter is being removed in joint making.

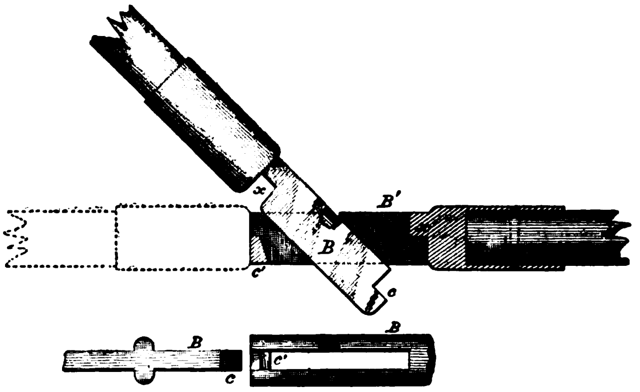


Figs. 14, 15 and 16.

It is known that fibrous cables depend upon their lead covering for the maintenance of insulation. Extra care is therefore essential that the terminals of such cables shall be well protected from moisture. Where these cables enter street lamps, vaults, etc., the ends are often covered with rubber strips to exclude moisture. In other cases a short piece of rubber insulated wire, carefully jointed to the fibrous cable, is used to continue the circuit to lamps. The Standard Underground Cable Company has recently introduced a simple device which has been found to give excellent results, while leaving the terminals of the cable quite accessible. It consists of a hard rubber tube separable into two parts, longitudinally, and having along one of its sides, apertures of a size suitable to receive any desired wire, Figs. 14 and 15. If the cable has several conductors the terminal of each is put through one of those holes and is then made fast to a binding post on the outside of the tube, Fig. 16. The other half of the tube is placed in position and the tube is then filled with an insulating compound impervious to moisture. The terminals of the conductors may then be freely exposed without fear of injury to the cable.

VIII.—CONDITION OF THE CABLES.

The general condition of the cables in the subways in the city is very satisfactory. Especially is this true of the high potential electric lighting circuits. There is as yet no indication of deterioration of the lead covered cables, the fibrous insulation retaining its original appearance, and the elasticity of the rubber cables being as pronounced as when the cables were first laid, in many instances from three to four years ago. It now seems safe to say that, barring mechanical or electrical injury, the life of these cables will be equal to that of their lead covering. As the percentage of mechanical injuries to the cables is small, and ruptures of the insulation due to the normal or momentarily abnormal pressures, or to lightning, have been very few, and there having been but one instance of deterioration of the lead covering, the life of the cables may be considered as practically unlimited. The only instance of deterioration of the lead covering of the cables of which the writer has knowledge was found to be due to the presence of ammoniacal salts in a cement lined conduit. It is assumed that the salts seeped through the conduits.



Figs. 17 and 18.

The lead covering of the cables is alloyed with 3 per cent. of tin to prevent injury from the cause just stated. In the cables more recently laid, a thin coating of tin is placed over the lead in addition to the alloy, as a further protection.

The high potential electric light circuits are tested weekly to ascertain the electrical condition of the insulation of the cables. The tests are, as a rule, made inclusive of lamps, converters, etc., but when an indication of trouble appears the cable proper is tested separately. The rules of the subways require the high potential circuits to show an insulation resistance of about 150 megohms per mile, but no difficulty has been found in maintaining it at an average of 500 megohms per mile.

The number of "burn-outs" or grounds on the high potential conductors during the past four years has been comparatively few, and with scarcely an exception those that have occurred have been due to defective joints or to mechanical injury. During the past year the total number of burn-outs was 12, and of grounds 13. With but one exception, the cause of which was unknown, these defects occurred in joints or were due to mechanical injury. In the case of one electric light company, operating over 100 miles of cables, there was not one burn-out or ground during the past year. In the case of another company, operating over 275 miles of cables, there have been but one burn-out and two grounds, due to mechanical injury and a defective joint. In addition to the foregoing, a number of defective joints not amounting to grounds were disclosed and located by the regular electrical tests.

As far as known, there has not been an instance of injury to the underground electric light cables of this city due to lightning. Lightning arresters are used at the entrance of the cables into the subways on a few circuits. The results seem to indicate that such arresters are not necessary.

IX.—HEAT IN THE SUBWAYS.

The presence of excessive heat along the route of the subways, due to defective piping of steam heating companies, threatened to be a source of damage to the cables in the subways, but this has been overcome by improving the construction of the steam pipes at some of the worst places and by changing their route in others; so that now, where in some places the temperature of the subways reached 200° F., it is but little above the normal. Prior to these changes, however, it was found that rubber compound cables could successfully meet the requirements of the subway rules as to insulation resistance, even at the temperature noted. (See THE ELECTRICAL ENGINEER, Aug. 12, 1891, on the "Effects of High Temperatures on India Rubber Insulation.")

The need for the employment of high grade cables, impervious to moisture, in the subways, has been more than once demonstrated when certain manholes and ducts have been temporarily flooded by leaks from adjacent water mains, or from natural springs.

X.—RODDING THE DUCTS.

The apparatus now employed in rodding the ducts preliminary to drawing in cables consists of the well-known screw and socket rod, so long used in chimney sweeping, and a newer device, more of the nature of a coupler, shown in Figs. 17 and 18, and known as the "Hart" coupler. It consists of a flat piece of brass B, attached to one end of a rod, arranged to fit into a slotted piece of brass B^1 on the end of another rod. Each rod, of course, is supplied with a strip and a slot at its respective ends. In coupling up, the flat strip B is held at an angle and slipped into the slot B^1. The rod is then dropped to a horizontal position, when the catch c on B^1 is caught against the inside end of B^1 at x^1 and the reverse catch c^1, or B^1, catches under the remote end of B, at x^1, thus holding the rods together. While this joint or coupling is quite loose, there is no likelihood of the rods coming apart in the duct since the diameter of the ducts does not permit a sufficient movement of the rods to allow the catch c to slip away from x. This device permits of much faster work than the screw and socket rods.

In rodding the distributing ducts, the surface boxes between manholes are opened to allow of manually guiding the rod through the boxes.

The original methods of drawing cables in and out of the ducts have been adhered to, namely, by hand, when the size or the number of cables will permit, or otherwise, by means of a windlass; a rope being, of course, properly attached to the cable in each case.

It has been found quite practicable to draw cables out of ducts when necessary, and to draw additional cables into ducts over other cables. As many as eight No. 4 B & S lead covered cables have been drawn into a three-inch duct. The four-inch duct will contain ten such cables.

SCOTT'S SLIDING SCALE ELECTRIC METER.

BY

W. B. Sisling.

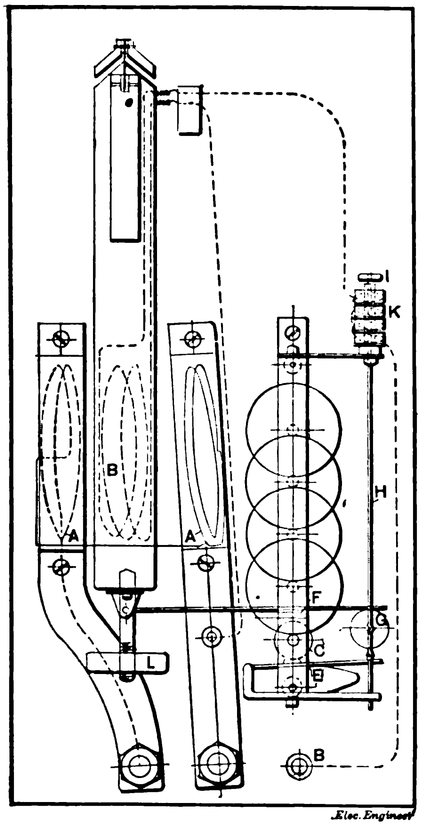
THE problem of the hour amongst electric supply companies in England may be represented by the question, "How can we regulate our charges in such a way as to increase our profit by enlarging our load factor?" The sliding scale based upon the ratio between the lamp-hours registered by the meter and the total number of lamps supplied therefrom (or fixed and connected ready to be switched on if required) has been thoroughly tried in Liverpool with a three-fold range of prices, and an interesting letter from the Liverpool Company's engineer, Mr. A. Bromley Holmes, which appeared recently in the London electrical papers, states that the method had to be abandoned, as it was found that the customers had some difficulty in understanding the scale, that the direct tendency of the arrangement was to limit the lamps fitted by a consumer to the smallest number he could possibly do with, and that the sliding scale was an obstacle to the introduction of the light into churches and other buildings not often used, but which might, nevertheless, be used during a time when the supply plant was not fully worked, as, for instance, on Sundays.

To overcome some of these objections, Prof. Kennedy has suggested the use of an instrument which would record the maximum current carried at any time during the quarter by the meter in connection with which it is used. This would have to be re-set quarterly by the inspector in the same way as a maximum and minimum thermometer. The sliding scale would then be based upon the ratio between the readings of the meter and of the maximum current recorder, and would thus place no restriction upon the number of lamps fitted up by the consumer but only upon the number used simultaneously. Thus far it would probably be quite satisfactory. But sundry small difficulties would have to be overcome.

The starting of a shunt motor, or the blowing of a fuse, might seriously increase the indications of the instrument, and therefore the price per kilowatt-hour for the whole quarter's supply. This difficulty might probably be overcome by using the heating effect of the current to operate the indicator, so that it would not register a momentarily increased current. Further, as the inspector would have to re-set the indicator, the company would have to rely entirely upon his integrity in resisting the bribes of any customers who might feel less anxious to act honestly than to wipe out the record of a dinner party rate of consumption.

Supposing, however, that these and similar small difficulties are overcome, does either this sliding scale arrangement, or the somewhat similar one suggested by Dr. Hopkinson, and referred to in the editorial in the ENGINEER of Nov. 30, tend uniformly to produce a large load factor? I think not, for both systems discourage occasional consumers at all times, whereas it would be to the supply company's interest to encourage them during the times of light load. The right way is, therefore, to cheapen the supply to all customers, occasional or otherwise, during the times of light load, and it seems to me that the problem is solved by the arrangement described below.

The accompanying engraving shows a diagrammatic view of the Scott electricity meter made by Messrs. Laurence, Scott & Co., Ltd., Norwich, England. As originally designed, a self-winding clock was included in each meter, which made it a somewhat complicated and expensive instrument, as the workmanship in an automatic apparatus of this kind must be very good. By doing away with the clock in each meter and arranging one clockwork apparatus in a central position to control the timing of a whole lot of meters, a very simple and practical system is made, which, notwithstanding that a special meter wire has to be laid with the supply mains, works out cheaper in most cases than the ordinary system of meters. The great advantage of the system, however, is that it enables the rates of charge for supply to be made different at different times of the day; this will be referred to further on.



THE SCOTT SLIDING SCALE ELECTRIC METER.

The meter itself is very simple, as will be seen from the diagram which shows all the working parts. Here A A are the fixed series coils of strip copper through which the current to the lamps flows. B represents the movable shunt coil whose resistance is about 1,500 ohms ; B is the terminal to connect to the special meter wire. C is the friction roller geared to the indicating train. E is a brake to prevent the friction roller C from being turned round otherwise than by the proper action of the meter. F is the friction pad which, when lowered onto C will communicate to that roller, and thus to the train, any movement of the suspended coil B. G is the roller on a vertical carrier H which is lowered when the armature I of the little magnet K is attracted. L is the adjusting weight.

The meter wires in connection with the terminal B are periodically connected up to the lighting mains by clockwork at the central position, or by a relay operated therefrom, so that a shunt current is periodically sent through the suspended coil B and through the little magnet coil K, pulling down the pad F into gear with the friction roller C, and thus communicating the forward movement or "deflection" of the suspended coil B to the roller C, this movement being exactly proportional to the current flowing in A A when the difference of potential at the terminals of the shunt coil is constant. When the shunt circuit is broken by the central clockwork apparatus, the friction pad is lifted off the roller C before B commences its backward movement, so that the indicating train is only moved in one direction, and the successive forward movements of B are integrated on it.

The meter works on the most accurate principle that is known, and very careful experiments have been made to find out whether there can be any error from the way in which the principle is applied. It has been found that these meters, as shown in the engraving, have an accurate range of over 100 fold, and this could be very much exceeded if there were any necessity for it. The meter is generally arranged to give accurate readings in Board of Trade Units when the shunt circuit is completed every 90 seconds. The shunt current remains on for about 12 seconds.

The central clockwork is arranged to make contacts with six separate circuits of meter wires one after the other, and as the resistance of the shunt circuit of each meter is about 1,500 ohms, 45 meters on each of the six circuits, or 270 meters altogether, can be worked with a total shunt current of 3 amperes. $^7/_{20}$ or $^7/_{18}$ cable is therefore amply large for the main meter wires, one branch wire of $^3/_{22}$ being taken from one of these meter mains to each meter on the customer's premises. For long distances and large numbers of meters a relay can easily be arranged in a junction box which will connect the next length of meter wire to the mains sychronously with the first length. The simplicity and consequent cheapness of this meter will more than balance the cost of the special meter wires in cases where the kind of mains employed permits of these being used.

If, instead of sending a shunt current into the meter once every 90 seconds, this interval is increased to 180 seconds, the meters will indicate only half the current used; the clockwork at the central position can be arranged so that the alteration can be easily affected, and if the alteration from a period of 180 seconds to a period of 90 seconds is made, say, an hour before sunset by the almanac all the year round, and back again at some fixed time during the evening, it is evident that during the whole of the ordinary working hours in the summer, and the greater part of them during the winter, the current will be supplied at half price, making the cost of power from electric motors compare favorably with that from gas engines. During these hours this will pay the supply companies, as most of their plant would otherwise be standing idle.

It may be objected that this "power" load will overlap the "lighting." load, but during this time the current will be paid for at the lighting rate, and there will be many instances where consumers will arrange so that they do not use power at these hours in order to avoid paying the higher rate. It will also encourage the use of *electric power during the summer time only*, as there are many manufacturers who have steam power that they would gladly stop during the summer months, but which they prefer to run in the winter, as they utilize the waste heat for warming their premises.

The periodic shunt currents can easily be made to record themselves on suitably arranged paper on which the time of day is also recorded, so that the record can be examined and filed for reference.

"THE POLE LINES ON OUR BLOCK."

ONE block in Burlington, Iowa, on Jefferson street, the one between Eighth street and Central avenue, now rejoices in 37 telephone, electric railway and electric light poles. They are of assorted sizes, colors and ages.

ON THE EXACT ADJUSTMENT OF STANDARDS OF RESISTANCE AND THE DETERMINATION OF TEMPERATURE COEFFICIENTS.—III.

BY

Elmer G. Willyoung

SINCE the two preceding parts of this paper were written, considerable additional work of the character which has been discussed has been done under my direction, with the previously described, and kindred forms of, apparatus. The results have been even more gratifying than those which have been given.

In connection with the work another new design of the apparatus has been produced which may seem to some to offer points of further advantage. The new design is shown in perspective in Fig. 9. As will be noted, the bridge and commutator are here combined in one piece so that the apparatus is complete in itself. The arrangement is, upon the whole, exactly the same as that shown in Fig. 3, the principal differences between the two being in compactness and simplicity of construction. The two commutators of Fig. 3 are so arranged that but *one* movement is required to effect the commutation, instead of two. This commutator, moving upon the rod C, really consists of two parts, one fitting upon the other. By using the upper head the whole platform is moved and the coils X and S (Fig. 1) are interchanged. By moving the lower head only, the *battery* alone is commuted thus enabling us *perfectly* to eliminate all thermal effects. This is a very important matter as the E. M. F.'s used are all so small that thermal potentials may prove greater than those employed, as was earlier pointed out. *The ability to commute the battery only is, consequently, of vital importance if good results are to be attained.* The pattern shown in Fig. 3 accomplished this by four movements (Fig. 5) as was shown; the new design, therefore, enables us to save two movements.

The two accessory coils S, Fig. 3, are here mounted in much the same way, but their terminals simply drop into mercury cups instead of being gripped by binding posts. The two coils under comparison are placed at the sides as before; by means of the binding posts a coil may be placed in multiple with the standard in determining the resistance of the bridge wire by the second method. (See Part I, p. 592, Vol. XIV.)

The bridge wire is permanently a part of the apparatus; it is 20 cms. long. The slider is provided with a vernier by means of which the wire may be read to $\frac{1}{20}$ mm. A very fine adjustment of the slider may be obtained by means of the screw nut attached to the rod upon which the slider usually moves but to which it may be rigidly clamped if desired. In order to have as low a resistance bridge wire as may be necessary, shunts are used, as in the cylindrical bridge, Figs. 6 and 7. The shunt is a wire of suitable size mounted upon a rubber strip and covered by a little zinc box A; two copper terminals, to which the shunt is attached, drop into two mercury cups so as to shunt the bridge wire. Different shunts may be used for different ranges of work. Each shunt may have stamped upon it the value of resistance of unit bridge wire division obtained by its use. This mode of varying the resistance of the bridge wire is much superior to the employment of a number of wires which may either be bodily changed or with which may be used an adjustable slider which may be placed so as to run above any particular wire desired. The greatest advantage lies in the fact that using shunts it becomes worth while to work down the bridge wire until it is perfectly uniform in resistance; a shunt will then merely lower its total resistance. If the wires are bodily changed either this large amount of labor must be applied to each one or else a different calibration curve must be used for each wire. Another objection would be the difficulty of always getting the same contact resistances at the ends of the wire; if made with mercury they would be variable owing to the instability produced by the contacts of the slider.

The apparatus is very simple to make, all the copper work being ordinary market-copper bars ½ inch square and bent into the required shape, the cups being drilled in the bars themselves. It is also very compact, measuring but 11 by 10½ inches over all.

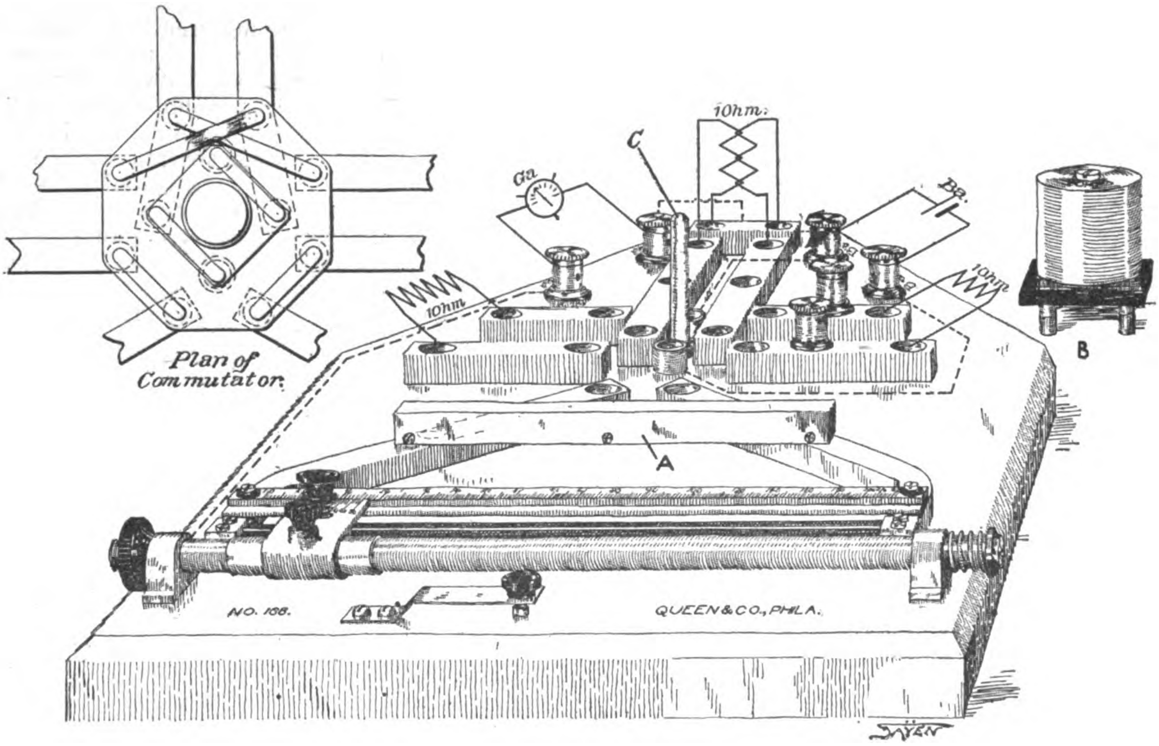


FIG. 9.—IMPROVED BRIDGE FOR COMPARING STANDARDS OF RESISTANCE.

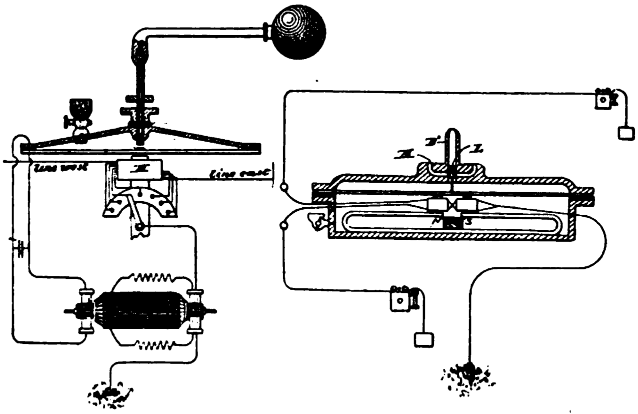
THE FIELD TELEPHONE REPEATER.

In order to increase the distance to which telephonic communications may be transmitted commercially, Mr. Stephen D. Field, the well known electrician, has conceived the idea of establishing communication between several distant points by damping the vibration at one point, and intensifying them at another. The principles of Mr. Field's device will be readily understood by reference to the accompanying diagrams, in which Fig. 1 shows the apparatus arranged at a relay station, while Fig. 2 shows a modification of the vibration producing mechanism at the same station.

As will be seen in Fig. 1, the telephone diaphragm is mounted upon, but insulated from a box, through the top of which extends an air tight tube connected with some device for exhausting the air from the chamber formed by the diaphragm and box, and having its mouth in close relation to the face of the diaphragm. On the upper side of the box is a cup filled with some filtering substance, and provided with a cock for admitting air to the box. Opposite the diaphragm is a polarized magnet with a coil, the terminals of which are connected to the line. The diaphragm and the frame of the box form the terminals of a local circuit including the primary coil of an inductive apparatus, a secondary coil of which is connected with the switch shown, and with the several communicating lines in multiple. The inductive apparatus consists of a shunt-wound dynamo whose armature has a low and a high voltage winding, the former connected with the local circuit, and the latter with the switch and earth, or return. The field magnet shunt is connected with the brushes through which the line currents are led.



Figs. 1 and 2.—Field Telephone Repeater.

Thus, when a partial vacuum is produced in the box the diaphragm will be forced inwardly by air pressure and will stop the opening of the tube which will remain in this condition until sufficient air leaks through the stop cock, when the diaphragm will withdraw by its own resiliency. A further exhaustion will then occur and the opening in the tube will again be closed. This cycle of operations occurs with extreme rapidity. With each opening and closing of the contacts formed at the mouth of the tube the resistance of the local circuit is changed and the dynamo is thrown from a condition of no load to full load; thus vibrations or undulations are thrown upon the lines, of such extreme rapidity as to be above the recording ability of electro-magnetic apparatus. The dynamo is so wound that the local circuit will carry a current having an E. M. F. of about one volt. Between the sides of this circuit is placed a condenser by which the sparking at the contact point may be reduced. Co-operating with the switch are a series of contacts by which more or less of the coil H may be given to the several lines.

For telephonic communication the usual transmitting apparatus may be employed, as indicated in Fig. 2. When signals are thrown upon the line from the distant stations, a disturbance of the balance of the two circuits occurs at the intermediate station and the normal vibration of the diaphragm is interfered with, and this, combined with the reaction between the two sections of the coil H, throws intensified vibrations upon the other line. The rate of vibration of the diaphragm is governed by the amount of air permitted to enter through the stop cock. In this way vibrations are repeated from one circuit into another with great rapidity and a very slight fluctuation at a terminal station is made to produce a very considerable change at the intermediate station.

INSULATED ELECTRIC CONDUCTORS.—XV.

BY

James Bowstead

The substances which can be used for insulating paints are quite numerous. In fact, nearly all kinds of insulating material may be thus used. To state it broadly, any insulating material which will form a *chemical* solution with a solvent containing no water, whether the solvent be simple or compound, and the solid ingredients of which do not separate during the evaporation or other change of the solvent when the solution is exposed to the atmosphere, will form paint of more or less value. But the number of such compositions which will meet the requirements of a first-class insulating paint is comparatively small. Referring to the above broad statement, the writer would state that there are many solid compounds which when dissolved in a volatile solvent form what *appear* to be chemical solutions, yet, when a layer of the mixture is exposed to the air, the solids will separate. This frequently happens when such paints contain paraffine wax as an ingredient. Again, there are many solutions which are chemically one so long as they remain hot, but the ingredients of which separate as soon as the solutions cool. Such materials should never be used for dielectrics.

There is an important fact relating to solid insulating material which is not generally known, and which should be remembered by manufacturers of insulated wires, namely, that most solids and perfect combinations of solids when applied by means of suitable solvents form bodies which are more compact, which adhere better, and which have a higher melting point than when applied while in a melted state. To illustrate: Take asphaltum four parts and rosin one part, and melt together. While the compound is in a liquid state apply, by means of a brush, a portion of it upon a tin plate, say, so as to form a thin layer. Then take another portion of the compound after it has cooled, make a varnish by dissolving it in naphtha, and apply to the same tin plate. The varnish may be used either warm or cold. After it has hardened it will be found, upon examination, that the compound which was applied in solution is harder to detach from the plate, is more tenacious, and requires a higher temperature to soften it than that which was applied hot. There has been no change in the material itself, and the difference in the properties of the two bodies is mainly owing to the fact that in one case the intermolecular spaces have been enlarged by heat, and in the other they have not, and the molecules therefore remain closer together both during and after the process of hardening. The above statement will apply to the majority of insulating compounds which have very low melting points; but the application of such compounds by means of solvents is not always advisable or necessary.

While treating of substances which can be used in the fabrication of insulating paints only such properties possessed by the substances as render them suitable for this particular purpose will be herein briefly enumerated. Other properties which the same substances possess and which adapt them for use in the formation of other kinds of dielectrics will be mentioned in the proper place when considering the production of such dielectrics. To name and describe *all* the substances which could be used in the manufacture of any one class of dielectrics would require too many articles; therefore but a few of the principal ones will be selected for illustration, and these will give the reader a general idea of the materials which may be used to form the various kinds of dielectrics.

Copal. This is one of the best and most permanent resins known. When properly prepared its specific resistance is about that of colophony. On account of its extreme hardness and brittleness it should be combined with material which will render the combination tough and flexible, as desired. Its proper solvent is pure linseed oil; and when it is once dissolved in oil it will combine directly with almost all other substances and compositions which are dissolved in the same oil. There are a few volatile solvents, simple and compound, of copal, but as the quantity dissolved by them is so small the solutions are of no use except for thin varnishes. Copal, in certain proportions, readily unites by heat with most resins and waxes, and when thus combined it can be more easily dissolved in oil than when used alone. To make a perfect solution of copal in oil requires considerable practice and skill, but if the following process is successfully conducted the resulting solution will be a clear and *permanent* one. Take a quantity of copal and separate it into different portions according to color, *i. e.*, place all the clear colored pieces in one pile, the dark pieces in another, and so on through the intermediate grades. *This is necessary* because of the different melting points of the various colored pieces. Then take any one pile and melt it over water, the heat being *above*, and allow the melted copal to drop into the water through perforations in the bottom of the containing vessel. Melt the other piles in the same way, and after all are melted, collect the mass, grind or crush to a coarse powder and dry *thoroughly* in a current of hot air. The copal loses weight during this treatment, but the resulting product is the pure resin which is now ready for use. To dissolve, carefully melt a convenient quantity in any suitable vessel, and have some boiling hot linseed oil ready in another vessel; when the copal is thoroughly melted pour the oil slowly into the melted mass and stir continuously until the copal is dissolved. If the loss of the copal resulting from this treatment is an objection to its use—for the loss sometimes amounts to as much as 25 per cent.—the copal can be dissolved in another way, but the result is not as good at that produced by the first method. To do this, melt the copal and add a large proportion of common resin to it. To this compound may be added other resins and waxes, and, if the copal is of an inferior quality, bituminous matter. While the compound is still liquid boiling linseed oil is added in the manner above stated and the whole boiled for from three to four hours. When sufficiently cool, turpentine may be added to thin the paint, but the less volatile the solvent in insulating paints the better.

The addition of copal solutions to other paints causes the resulting paints, when dry, to become harder, more brittle, more durable, and to have a higher melting point. But it also causes them to dry more slowly.

THE PRENTISS INCANDESCENT LAMP.

In order to afford ready access to the interior of incandesent lamp bulbs for the purpose of renewing broken or burned-out filaments, Mr. T. H. Prentiss, of the Buckeye Electric Co., has designed a method of making a portion of the bulb of a softer glass than the remainder, so that the glass bulb being separated into two parts on a line passing through the section of softer glass by means of any cutting tool, or by cracking, may be reunited by fusing, after the substitution of the new filament. The portion of softer glass forms a section of the bulb below the metal cap, so placed that after separation easy access can be obtained to the points of connection between the filament and the platinum wires.

ROTATION OF THE MAGNETIC FIELD.

BY

Chas. Steinmetz.

A part of space, where magnetic forces are acting, is called a *magnetic field of force*. The magnetic force at any point of the magnetic field is—analytically as well as physically—represented completely, in all its inductive and mechanical effects, by two quantities, the *intensity*, and the *direction* of the magnetic force. In Faraday's geometrical representation of the magnetic field the *density* of the *magnetic lines* corresponds to the *intensity*, the *direction* of the magnetic lines to the direction of magnetic force. Consequently, as long as the two characteristic quantities of the magnetic field, the *intensity* and the *direction* of the magnetic force, are *constant* in any point of space, the magnetic field must be said to be *stationary and constant* at this point of space, and any representation of the magnetic field which does not conform to this, has to be rejected as not giving a correct representation of the phenomenon. While on the other hand, if intensity or direction of magnetic force at any point of space vary in time, the magnetic field at this point is a variable function of time, which may be a periodical function, or not.

Now let us examine the case of a cylindrical, uniform magnet, revolving around its axis, either a permanent magnet, or a cylindrical iron core with a concentric magnetizing helix, in the latter case both, or only the core, or the helix revolving. In any one of these cases, intensity and direction of magnetic force are constant functions of time, that is, stationary, at any point of space, and consequently the assumption of any rotation of the magnetic field is not warranted.

In the case of a horseshoe magnet revolving around one of its legs, the magnetic constants at any point in space are periodical functions of time, and at all points of a circle concentric to the axis of rotation. These functions are identical, but differ in phase progressively; but this does not involve the rotation of the magnetic field any more than the tides of the ocean—which are periodical functions of time, differing in phase in space—mean a rotation of the waters of the ocean around the earth.

THE ELECTRICAL CONGRESS.

Dr. Elisha Gray, chairman of the World's Fair Electrical Congress, has issued a call to his Advisory Council for a meeting in New York on Januray 17, when two reports will be considered and acted upon, as determining the Congress programme—one from the English Committee and the other from the Congress Committee of the American Institute of Electrical Engineers. Both these documents have been put in type and distributed to the members of the Advisory Council in this country in advance of the meeting, so that the work can be actively prosecuted as soon as the Council has closed its session on the 17th.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 208 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XV. NEW YORK, JANUARY 11, 1893. No. 245.

MR. TESLA'S HIGH FREQUENCY WORK.

IT is now nearly a year since Mr. Nikola Tesla, after his brilliant demonstrations here, scored such decided triumphs in the lectures which he delivered abroad at the invitation of various scientific societies; yet the interest which is manifested in his recent work not only by electricians but by many laymen, is such as to make highly welcome the publication of the abstract of Mr. Tesla's lecture, prepared by him for, and just published in, the Transactions of the Royal Institution of England. In this abstract, Mr. Tesla gives a succinct account of the reasonings and experiments which led up to the results obtained by him, and, taken altogether, they present a remarkable array of experimental facts in a field entirely new. Although replete with facts and suggestions, many of them quite new, it must be evident that the paper embodies but a tithe of Mr. Tesla's work in this field, the complete record of which would fill more than one volume of surpassing interest. Those who attend the convention of the National Electric Light Association in St. Louis, next month, will have an opportunity of witnessing some of Mr. Tesla's experiments in a lecture which he has consented to deliver before the Association.

EMANCIPATING THE CANAL MULE.

IN his message to the Legislature, Governor Flower, of New York, remarks that only steam canal-boats capable of towing three to five boats each trip are now able to compete successfully with the railroads in the transportation of freight, and he suggests the inquiry, whether by the application to the canals of the "deadly trolley," it might not be possible to increase the speed of transit from the present average rate of two miles per hour to the maximum which is possible without injury to the banks of the canal, which is about four miles per hour. He points out that abundant water-power for the purpose is available at many points along the line of the canals, which might be utilized at a comparatively small expense. He thinks the electric plant should be owned by the State, and expresses the opinion that the necessary power could be supplied to each boat at a price not exceeding sixty cents per day. We agree with the Governor that the scheme ought to be tried, and we believe it to be perfectly practicable. Doubling the speed would increase the carrying capacity of the present canal fourfold, and would at the same time enormously diminish the cost of conducting transportation. Let the patient canal-mule be emancipated. His brother, the car mule, was freed long ago by the trolley.

SLIDING SCALE ELECTRIC METERS.

THE problem of bringing up the load of a central station to as uniform a character as possible ought to be as much the concern of the station manager as that of increasing the existing maximum. Indeed his efforts in this direction ought to be, if anything, concentrated on securing a uniform load diagram for reasons which are too plain to need further remark. How to encourage the consumption of electric energy during the present light load hours has been the subject of serious consideration, and has with us in America found a ready solution in many cities by the large and increasing number of motors connected to central stations. But in England where the advantages of the electric motor are still slow to be recognized, special inducements have to be offered to consumers to use current during the present light load hours; and the most enticing of these is a reduction of the charges for current during light load hours. How to differentiate current consumed during the periods of light and heavy load, was a problem of no small difficulty. The method suggested in the Scott sliding scale meter described by Mr. Wm. B. Sisling, will therefore prove of interest as offering one solution of a problem which may have to be met by not a few even among our own stations in this country.

LAMINATION IN ELECTRICAL APPARATUS.

IN last week's issue we began a series of articles from the facile pen of Mr. Thomas D. Lockwood, on a subject, the importance of which it is hardly necessary to dwell on, in view of its far reaching character in the construction of electro-magnetic apparatus. This brief sketch, historical and technical, of the lamination of iron in such apparatus, will, we are sure, prove of the utmost value to workers in the field of electrotechnics, and the exhaustive research bestowed upon it by Mr. Lockwood, furnishes a valuable record.

The Index for Volume XIV.

THE index for Volume XIV, accompanying this number, will be found useful on account of its careful subdivision of subject and complete cross references. In its variety of contents enumerated and in the large number of authors it includes, remarkable evidence is given of the wide and growing range of electrical work and investigation.

CENTRAL STATION ECONOMY.

BY

Francis B. Crocker

I DESIRE to express my appreciation of Mr. J. H. Vail's articles on "Increased Commercial Efficiency, and Higher Economy in Central Stations," which appeared in the ENGINEER during November and December. These articles are examples of the valuable contributions which competent and experienced engineers can make to their brethren, and which tend more than any other one thing to improve electrical practice.

I fully agree with Mr. Vail in that while large direct-connected engines and dynamos are, of course, very economical and desirable in themselves, nevertheless there are two other important facts to be considered. The first of these is that the generating plant must be divided into several separate units, since we cannot depend upon a single large unit for fear of a break-down. Consequently, we can only use large units where the load is large, that is, several times as large as any one unit. This refers to the total or maximum load.

The second fact is that large (particularly triple expansion) engines are very inefficient at light load; which is apt to be the case. Consequently we should not employ very large units when there are long periods of light load, which is apt to be the case in electric lighting.

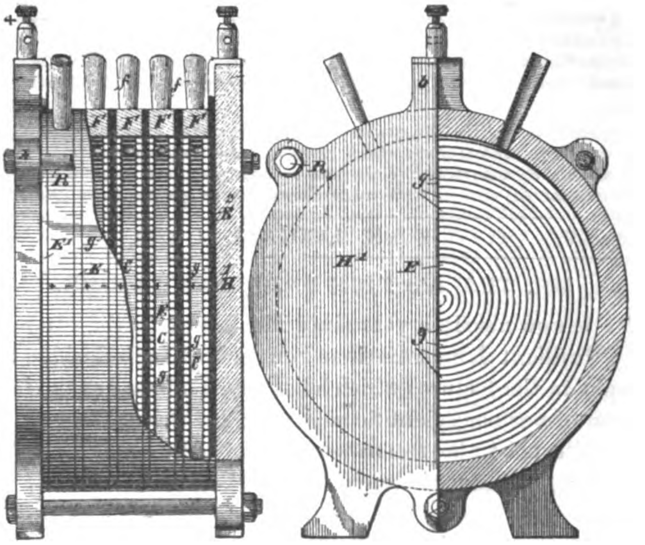
In view of these facts, Mr. Vail states that stations of medium capacity should be equipped with two or more smaller engines for service during the hours of small load. It has always been an inexplicable matter to me why this plan is not more often adopted in electrical generating plants. It is even possible to divide the time into two or more periods, and the size of the units can be made to conform to these periods within reasonable limits. I know of a case where a comparatively small engine and dynamo carry the load during the day and late at night, and a large engine and dynamo are used for the heavy load during the evening. In each case the engines run at about three-quarters load during most of their respective periods, the results being that both convenience and economy are secured. If both units were of the same size, which is the ordinary, stupid plan adopted, then one unit would be underloaded, and therefore inefficient for the day load, and both units would be required for the night load, and they too would be underloaded most of the time.

In connection with discussions of this sort there is one common, but very natural fallacy, and that is, to consider *percentage* of efficiency only and not the actual loss. Taking, for example, Mr. Vail's table of the "Comparative Commercial Efficiency of 2 × 50 K. W. Generators under Various Loads," we find that at 11,900 watts load the commercial efficiency is given at only 47.7 per cent. This *sounds* very low, but if it be remembered that the total indicated horse power in this case is given as only 18.22 and the *total loss* therefore is less than 10 h. p., then it is seen that the actual cost of running the plant at this low efficiency over and above what would be required at perfect (100 per cent.) efficiency is probably about ten cents an hour, which is insignificant compared with the total expenses involved. A difference of five per cent in efficiency at maximum load, which is given as 166.3 IND. H. P. would amount to about as much as the 52.3 per cent. loss at the light load. To take an extreme case: An engine running without any useful load and consuming, say, 10 H. P. in friction would have *zero* efficiency but the actual loss might be much less than in the case of another engine running with a large load at 75 per cent. efficiency. It is a question of the *total cost per annum* of running a station and not what is the *percentage* of efficiency at any particular time. It is, indeed, a fortunate thing that a large *percentage* of loss at light loads is a small matter in actual cost. In the case of electrical *conductors* on the other hand the largest percentage of loss is at the largest loads; consequently the total actual loss is great.

THE WLADIMIROFF ACCUMULATOR.

AN accumulator in which the same electrode forms the positive pole of one cell and the negative pole of the adjacent cell has recently been devised by Mr. Nicholas Wladimiroff, of St. Petersburg.

The battery which is shown in section and inside elevation in the accompanying engravings, consists essentially of two heads or head plates, H, and H', of a series of frames, F, each provided with two feed apertures for the reception of glass feed funnels, *f*, for supplying the acid solution, and a series of electrodes, E, of which there is one between each two frames, whereby the cells, are formed, the initial and terminal electrodes, E' E², of the series being secured between the corresponding frames and the heads, respectively, against which latter they bear, the whole being firmly united by means of tie rods. The electrodes have both of their opposite surfaces of like chemical nature and have a spiral groove formed in their opposite faces, for the better retention of the active material by means of which the latter is formed into a spiral column provided with a continuous or unbroken support, and by which the active surface of the electrode is materially increased.



THE WALADIMIROFF ACCUMULATOR.

IMPROVEMENTS IN ELECTROCUTION.

WARDEN BROWN, of Sing Sing Prison, in a letter to Governor Flower under date of Dec. 19, regarding the execution of McGuire, says: "By a new and modern appliance of electricity applied to the execution of this man, the shock was reduced from 1,800 volts to 150 volts within three seconds, and one contact was sufficient to make life extinct. This modern appliance, which has grown out of experience learned by the electrocution of ten men, does away with all possibility of any burning, scorching, etc."

It is reported that a complete electrocution plant, embodying all the latest improvements, will be shown at the World's Fair, on the instigation of Mr. Gerry.

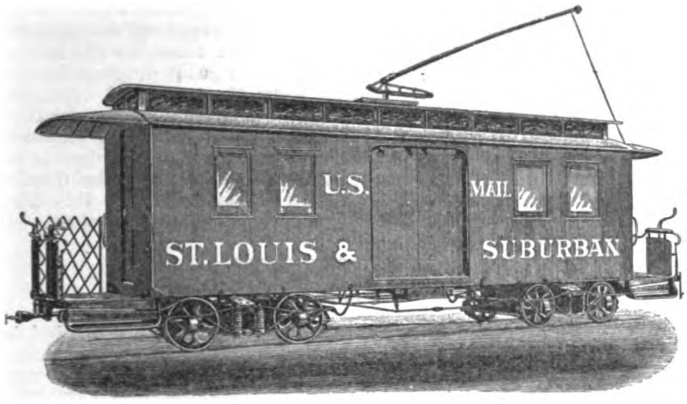
WHITTIER BELIEVED IN ELECTRICITY.

THE inventory of the estate of Mr. John Greenleaf Whittier (amounting in value to $133,730) shows that the greater portion was invested in various railroads and electric stocks, and that the money was so distributed that over 100 different investments were on the list, the amounts being about the same.

ELECTRIC RAILWAY DEPARTMENT.

THE ELECTRIC MAIL CAR IN ST. LOUIS AND OTHER CITIES.

THE proposition to establish an electric conduit trolley system for the dispatch of mails between New York and Brooklyn has attracted public attention to the increased facilities afforded by electric traction for the expedition of the mail service in general. In some cities, the cable cars are utilized for the purpose, and those on the One hundred and Twenty-fifth street line in this city are so labeled. The Elevated trains also carry mails, in a very loose and slipshod fashion. But it is with electric trolley cars that the best opportunities present themselves, and perhaps St. Louis is the most conspicuous example of their use. The cut shown on this page illustrates the special mail cars used on the St. Louis and Suburban Railway Company's lines. Mr. Thos. F. Sneed, the general superintendent, writes us that the car travels over a system embracing 19 miles, making three trips daily. Baggage matter is also handled with the mail matter. The car is constructed on the regular U. S. Postal Car plan, all the arrangements being complete for receiving and distributing mail while *en route*. The aggregate run of the car in making its three round trips is 114 miles, and the time occupied on each trip is 3 hours 12 minutes. The car leaves the post office at 6.25 a. m., for its first trip, and arrives at Cabanne at 7 o'clock. It is met at ten or eleven way stations by the carriers assigned to routes in the adjacent districts and exchanges of mail are made. Returning, the car leaves Cabanne at 9 o'clock, and mail is delivered at the post office at 9:33; and at 9:50 the car starts on another trip. By this means mail is delivered much more promptly in the sections of the city which can be conveniently reached from the St. Louis and Suburban road. The two postal clerks are busy all the time sorting and stamping, and in the process of distribution. The mail for delivery at stations along the car route is at once, after stamping, handed out again at the proper station. It will be seen that by means of this post-office car, letters intended for city delivery will not go through the tedious and dilatory routine of being first taken to the general office, stamped and then sent out again by carrier. City letters can be delivered in half an hour, and all letters can be speeded to their destination with a saving of some hours.



ST. LOUIS ELECTRIC MAIL CAR.

As to the baggage or freight service, Mr. Sneed remarks that it is strictly local, and in no way affiliated with that of any outside company. The street railway charter only permits the carriage of family supplies, excluding coal, and that only west of Vandeventer avenue where the line connects with the "Old Steam Division" right of way. The mail matter, however, is now handled over the entire length of road.

The car itself has regular motor and trolley pole equipment. Inside it is fitted with mail boxes, hooks for pouches, etc. It is 44 feet in length; 7 feet 10 inches wide; 11 feet 4 inches high; length of car body 36 feet; height inside at centre 7 feet 9 inches; opening of side door 4 feet.

It seems worthy of remark here that such a utilization of the trolley and cable tracks in New York should do much to expedite the now disgracefully slow mail service. There is no longer any certainty in the delivery of letters, while newspapers are like bread cast upon the waters—it is many days before they turn up. While the present article was being prepared, its writer received a paper mailed down town 30 hours before; and the same delivery has often taken more than two days. Evidently it would expedite things to abandon mail wagons as far as possible and concentrate postal energies on the street cars. That would be at least one measure of relief in many of our rapidly growing cities. Postmaster Harlow of St. Louis is understood to be well satisfied with the results. There is a further interesting feature of the case, suggesting a possible extension of the idea. While the great strike was on in New Orleans recently the mail authorities were advised to have the street cars defined as mail handlers, inasmuch as letter carriers were obliged to employ them for prompt distribution. The scheme met with favor, and papers are being drawn up covering the matter and are to be forwarded to the Postmaster General. Postmaster Eaton will be asked to consider the advisability of placing letter boxes on all street cars, and thus they will be made to serve Uncle Sam as well as the public, and at the same time be under Government protection. In such an event no such thing as a street-car strike, involving the summary stoppage of the cars, would be practicable. The car lines, in New Orleans are being rapidly converted into trolley systems.

A SWEEPING TROLLEY VICTORY IN PHILADELPHIA.

THE Supreme Court of Pennsylvania rendered a decision on January 3, in the trolley cases, and the judgment was a complete victory for the Philadelphia Traction Company, which is authorised to build an electric trolley railway system over nearly 100 streets in the city. The opinion of the court was delivered by Justice Mitchell.

In brief the court states that the questions submitted for its decision were: First, has the Legislature authorized the railway companies to do the acts complained of; and second, if so, has such authority become operative by the consent of the municipal authorities validly given? Upon the first point the court finds that the act of May 8, 1876, authorizes passenger railway companies in cities of the first-class to substitute other than animal power whenever authorized by city councils, and contrary charter limitations are repealed. The court finds that this act is constitutional, and supplies the authority wanting in the charters of the several companies. Upon the point that the consent should have been given to the Traction Company, the lessee of the several companies to which the authority is actually given, the court holds that the lessee and lessor are, to all intents and purposes, one corporation, and "the circumstances leave no room to doubt that the consent of councils was that the thing should be done by the two corporations acting together as one; and such consent, whether it named one or the other, was meant to be operative as to both. This is the common-sense view of the action and intent of councils, plain to all men."

This decision establishes the validity of the seven ordinances of March 31, 1892, granting the trolley franchise to the Union, Continental, Philadelphia and Gray's Ferry, Catharine and Bainbridge, Thirteenth and Fifteenth Streets, Twenty-second Street and Allegheny Avenue and Empire Passenger Railway Companies. These ordinances were vetoed by Mayor Stuart and passed by councils over his veto. They provide, after enumerating the streets to be occupied: "Said motors to be supplied from overhead wires, supported by iron poles not less than 20 feet high, which the said company is authorized to erect and maintain, and to be placed opposite each other, within the curb lines, and connected with street wires, or at the option of the company to be erected in the middle of the streets with a double bracket thereon suspending the overhead construction. Provided that in the construction and operation of the system of wires and poles herein authorized, the same shall be so constructed and operated as not to interfere with the construction and operation of any elevated railroad heretofore authorized by councils. The same shall be under the supervision of the Director of the Department of Public Safety. Before said company shall exercise any privilege hereunder it shall first pay $50 into the city treasury for the printing of this ordinance."

There are no restrictions, limitations or conditions in any of the ordinances, except as mentioned above. The agreement to pave 40 miles of streets, presented to the mayor and to councils, was never accepted by the authorities, and there is now no legal obligation upon the Traction Company to do this paving. President Widener declares, however, that the company will live up to its agreement.

With regard to this decision, Mr. P. A. B. Widener says that it will add $100,000,000 to the real estate values of Philadelphia in a very short time. About $5,000,000 will be spent in introducing the trolley system and of that about $1,000,000 will go in new paving.

When asked about the first line to be equipped with the trolley, Mr. Widener said that the extension of the Bainbridge and Catharine streets road along Gray's Ferry avenue to the bridge would be constructed as soon as possible in order to accommodate the thousands of working people employed in that locality. The Morris and Tasker streets line, about being completed, will next be connected by way of Long lane with the road to Point Breeze, which, although finished for some time, has not been operated.

The first main line of travel upon which work will be begun as soon as the weather permits is the Thirteenth and Fifteenth streets road. After this it has not yet been decided on what lines work will first be pushed. It is the intention of the Traction Company, however, to equip all the roads comprised in the ordinance as soon as the necessary material and labor can be had.

In addition to these lines it is the purpose of the company, President Widener said, to ask councils for the privilege of using the trolley system on the Ridge avenue road from the depot to Manayunk. It has not yet been determined what motive power shall be used on the lower end of the line.

The trolley system in operation on Bainbridge and Catharine streets, President Widener claimed, was the ideal system of the country, and it will be the same as will be used by the Traction Company on all its lines. Especial attention will be given to the road bed. Solid rails, weighing 92 pounds to the yard, will be used, and only the most approved materials and best workmanship employed.

The different lines could be equipped with the trolley system for much less than $5,000,000, Mr. Widener said, but it is the intention of the company to spare no expense in securing the very best method of electrical street car propulsion.

A complete equipment of about 1,000 new cars will ultimately be provided, both for summer and winter use. They will have four wheels and be about ¼ larger than the new cars on the Bainbridge and Catharine streets line, but it is claimed that they will not have any rocking or jerky motion, because the weight of the motors will keep them steady, and the solid roadbed will obviate any jolting.

Additional boilers, engines and dynamos will be constructed at the power house of the Bainbridge and Catharine streets road to furnish the current for the operation of the Spruce and Pine, its extension to Fairmount Park and Gray's Ferry bridge, and possibly over that structure to connect with the railway on Woodland avenue or Darby road. Besides these, power will be furnished to the Morris and Tasker, Christian and Ellsworth streets lines.

Another power house is to be located in the northern section of the city, which will supply the electrical current for all the traction lines designated in the ordinance and also for the Frankford and Tacony Railway, which was recently authorized by ordinance of councils. When all the Traction Company's lines are operated by the trolley as at present contemplated, 4,000 car horses will be taken off the streets.

A SLEET WHEEL INSTEAD OF TALLOW.

A UTICA, N. Y. paper says: Superintendent W. M. Sturges, of the Belt Line Railroad, has invented and caused to be patented a new device called the "Sturges Sleet Wheel." Heretofore, when it has been found difficult to operate the cars because of sleet and ice gathering on the trolley wires, men equipped with buckets of grease and tallow, and a long pole on one end of which was a bundle of rags, have mounted the cars and greased the wires. This was quite an ingenious remedy, to be sure, but it was effectual only in part. When ice had already formed it would not remove it, but if applied before the ice formed it prevented any great accumulation. Mr. Sturges's device does more than this. It was tried this morning and proved conclusively that it would remove the ice just as quickly as a red hot iron.

The contrivance is a simple one. It is a wheel, just the size of the ordinary trolley wheel, and in just a minute and half the trolley wheel may be removed and this one placed in its stead. The sleet wheel is made of bronze and is divided in the centre of the groove into two parts. The parts are not solid, but are divided in sections like the old fashioned horse car wheels. On each of these sections is a shoulder which comes into direct contact with the trolley wire, and when the wheel revolves the shoulders scrape the ice from the wire as neatly as a knife. The first cars sent out this morning were not equipped with the new wheels, and consequently were stalled when part way to their destinations. The second run of cars on all the lines were so equipped. They not only made the runs on time, but pulled the stalled cars along with them. On the New York Mills line the sleet-wheel car brought a New York Mills and a Whitesboro car back with it and ran into the yard on time. Superintendent Sturges is confident that nothing but deep snow or broken machinery will interfere with traffic this winter.

COMBINED ELECTRIC RAILWAY AND LIGHTING PLANTS.

BY

C. J. Field

I HAVE noted the article by Mr. McCay in THE ELECTRICAL ENGINEER on the operation of combined railway and lighting plants, and have read it with pleasure and profit. For the past few years we have earnestly, on every occasion, been the strongest advocates and friends of the advantage and desirability of the combination of electric lighting and railway plants in the small class of towns. From our own experience, in the ones we have built, we believe there is no better investment or opportunity of profitable re-organization of many of the small railways and lighting plants which are now operating on a very small margin of profit.

The figures presented in the article in question we have seen demonstrated, and even stronger cases than this. We know of railway and lighting plants which separately, were on a non-productive basis, and which, combined into a new and modern equipment with energetic management, have made a large and profitable return on the capitalization.

The only point I would criticise in Mr. McCay's article, in which he seems to have not had the very latest information on the matter, is in the cost of power operating expenses on properly equipped large plants. I do not consider that the old figures published by the West End Company are a guide or precedent in the matter at all. These figures were the result of operating under very poor conditions. We know of several plants which we have built and equipped in which the power operating expenses were 1½ cents per car mile, and even under; but these figures are on plants of much larger capacity than this one, and the obtaining of practically the same figures on a small plant of this kind can only be accomplished in a combined station of this class.

ELECTRIC RAILWAY CROSSINGS.[1]

THE introduction and growing use of street cars propelled by the trolley system has brought before the minds of railway managers the question of safety at crossings where the electric road intersects other passenger lines. It is a question which frequent accidents make pressing, for the danger of collision is much increased under electric propulsion. One of the main arguments used to gain assent to the substitution of trolley for horse power is that real "rapid transit" will be thereby secured. But cars cannot move rapidly through the streets without doubling the peril of accidents, particularly at crossings with other railroads.

Horse cars seems to have been regarded originally, so far as danger is concerned, as only a modified form of wagons and other horse conveyances. Their lines cross each other at the will of the promoters, it being thought apparently that horse cars could stop as easily as wagons, and needed only to be governed by the same rules of the road. But rapid transit alters the case; faster cars demanded and promised as a recompense for the permission to use electric motors, to introduce to a more or less degree exactly the question of safety long debated about steam railroad crossings, and which has by general demand been partly solved through the use of safety appliances. As the use of trolley cars continues to extend through city streets or country roads, safety to the public will surely require, as on steam railroads, that crossings be protected by the best apparatus. Already we have a long list of collisions, attended always with loss of property or injury to persons, and often with loss of life, where a trolley car ran into another electric car at a crossing, where cable and electric cars collided, or where trucks and teams have been struck while crossing at right angles along a public street. This is one more reason why the trolley should not be used in crowded streets like those of New York City, but it is also a reason for greater precaution in any street or road where the electric car has been introduced and where other streets or roads cross the electric tracks. Speed has its advantages and is a rightful aim in its proper place, but clearly it has also its obligations as to protection for the public safety.

An important part of the subject is the crossing of a steam railway by an electric road. The whole matter of steam railway crossings at grade is a complicated one, particularly as to the division of the expense of removal; yet the feeling is growing that the crossing of a steam railway by a wagon road at grade is such a source of danger that sooner or later some way must be found to do away with it. If this is true as regards the ordinary traveled highway, it is doubly true in cases where the electric car at high speed crosses the steam tracks. No mere flag-waving can insure safety in such a case. In advance of the removal of the grade crossing through the elevation of the steam or the wagon road, such an electric crossing ought to be protected by the best known automatic appliances, including the modern device of derailing contrivances working automatically in the presence of danger. Since all accounts agree that the trolley system of propulsion when allowed on streets or roads is very successful financially, yielding large returns to the companies beyond the interest on the cost of substituting electricity for animal power, it is proper that those profiting by the new motor should guard the public at their own expense. In short, the trolley companies ought to be compelled to pay for the needed safety apparatus, and provision for the protection of the public ought to be a part of the regular estimate of cost made in changing old lines or building new ones. It is generally recognized that electrical propulsion in some form will undoubtedly be the future power for street and road railways; it is important that now, before the field is entirely turned over to electricity, we should provide adequately for the dangers which rapid transit invites. We cannot have advances in passenger carriage without the accompanying drawbacks, but we can at least insist that wherever the fast car travels, it shall find the public safety everywhere guarded by the best appliances known.

CONSOLIDATION OF ELECTRIC RAILWAY INTERESTS IN BROOKLYN.

THE details of the plan by which the Brooklyn City Railroad Company, with its $12,000,000 of capital and its 83 miles of street railroads, is to be leased to a syndicate to be known as the Long Island Traction Company have been made public in a long statement issued by President Daniel F. Lewis. Prefacing his statement, Mr. Lewis said that many offers for control had been made and declined, but that one had now been submitted which he thought would be of great benefit to the stockholders.

The proposers, whose names he declined to give, have formed a syndicate and are represented by the New York Guarantee and Indemnity Company. They propose to lease the road in bulk, paying the stockholders 10 per cent. a year on their holdings, and depositing $4,000,000 with some trust company as a guarantee. The statement continues:

"The syndicate is to give to the stockholders of the Brooklyn City Railroad Company the right to purchase three shares of the traction company's stock of the par value of $100 each for every 10 shares of the par value of $10 each held by the stockholders of the Brooklyn City Railroad Company at the date of the delivery of the lease, at $15 per share; when the holdings of any stockholder of the city company shall be less than 10 shares he shall be entitled to his proportionate share of traction company stock in scrip.

"The capital stock, to begin with, will be fixed at $30,000,000, and this arrangement will place in the stockholders of the Brooklyn City Railroad Company $\frac{9}{10}$ of the capital of the traction company; the remaining $\frac{1}{10}$ will be allotted to the members of the syndicate, but shall be paid for at the same rate as that paid for by the stockholders of the Brooklyn City Railroad Company. This arrangement will place the control of the traction company by a large majority in the hands of the stockholders of the Brooklyn City Railroad Company.

"The right to subscribe for the $3,000,000 of the capital stock of the Brooklyn City Railroad Company (after the present $3,000,000 about to be issued to the stockholders are taken by them, the issue of which is authorized) is to remain with the stockholders of the Brooklyn City Railroad Company, and will no doubt be issued to them at par during the year 1893.

"The surplus in the treasury of the Brooklyn City Railroad Company at the date of the delivery of the lease will be divided in due time among the stockholders of the Brooklyn City Railroad Company.

"Rights to purchase the stock of the traction company and to subscribe to the unissued stock of the Brooklyn City Railroad Company will be arranged so they may be disposed of by stockholders not wishing to make the purchase or subscription."

THE LEBANON, PA., ELECTRIC RAILWAY.

THE LEBANON AND AMESVILLE ELECTRIC RAILWAY at Lebanon, Pa., is said to be one of the most complete in the country in point both of construction and equipment. The charter was granted in 1890, work was commenced in the spring of 1891 and the first car was run over the first section on August 17, of the same year. The entire road was completed last September. The capital stock, originally $60,000, was afterward raised to $100,000, and during the past summer $100,000 of five per cent. bonds were issued, all of which have since found ready takers.

Encouraged by the success of this road, the Lebanon & Myerstown Electric Railway Company has now been formed with $100,000 capital stock. The charter has been secured, all damages settled and the new road, which will be seven miles long, will be commenced in the early spring.

AN ELEVATED ELECTRIC RAILWAY FOR PARIS.

IT is stated that a syndicate of engineers has applied for the privilege of constructing an elevated road in Paris to be operated by electricity. The project divides the city into two parts by a line running north and south. A new street, 165 feet in width, will be built, which will open into the principal quarters, the Bourse, the Halles Centrales, the Palais du Senat and the Jardin des Plantes. The central part of this route will be reserved for the elevated line, which will have two tracks resting upon four rows of iron columns, 23 feet in height. The projected line will connect with the Metropolitan railway and with the important lines which already exist.

TROLLEY ROADS FOR RURAL NEW YORK.

THE building of electric railroads through Westchester County is occupying the attention of the people in all the towns where they may be put in successful operation. It has been suggested that it would be a good investment for the local capitalists to connect Verplanck's Point, Montrose and Centreville with Peekskill by an electric railroad. There is much travel between these points, and the road would be well patronized. The distance is short and several thousands of population would be reached and benefited. Nothing, it is argued, could be done that would give such a stimulus to business in Peekskill as the connecting by electric cars of the small hamlets in the vicinity of this place, which is soon destined to become a city.

Lake Mohegan, a popular summer resort, now reached only by stages, lies on the east, and Annsville, near the State Camp of Instruction, Oregon, and Lake Oscawana to the north and northeast, are all within reasonable distance and are places important enough to be more in touch with the centre at which they get their supplies.

MISCELLANEOUS.

AN IDEAL CENTRAL POWER STATION.[1]—II.

BY C. J. FIELD, AND THE ENGINEERING STAFF OF THE FIELD ENGINEERING COMPANY.

BOILERS.

After the engines, one of the next most important factors of a power station is a good type of boiler. There may be said to be boilers and boilers, many types of them, but if we look carefully over the field we can in general bring them down, as far as concerns a power station of this kind, to three types or classes: First, the plain horizontal return tubular boiler, which has probably been more largely used in power station and mercantile work than all the other boilers combined, and where there is ample space and a working pressure not exceeding 120 or 125 pounds is required this type of boiler probably more fully meets general requirements than any other. Under the second head comes in the sectional or water tube type of boiler as manufactured by Babcock & Wilcox and many other firms in the same line. This sectional water tube type of boiler has been more extensively used, probably, than any other where high pressures were required, and it has in general cases met the requirements of this practice. We found, however, in some particular parts of our work, especially in power work, where the load is subjected to violent fluctuations, that this sectional type of boiler lacks steam room capacity to stand the violent fluctuations of load. This has caused engineers to look around for some other boiler which would combine the advantages of the horizontal return tubular and of the sectional. Without experimenting too much it seemed, on looking over the field, that the boiler which had been so largely developed for marine practice, as the internally fired marine type of boiler, offers the best solution of the difficulty with some modifications and changes. We therefore classify this as the third style of boiler adapted for this kind of work and have used it in this station. Its advantages in development for high pressures have been demonstrated by long experience, also for economy in space occupied, economy in operation and good steaming capacity. Such a type of boiler is described in the following specifications:

BOILER SPECIFICATIONS.

Type.—Internally fired, direct fire tube marine boiler.

Pressure.—To be tight under 160 pounds working pressure and tested to 210 pounds hydrostatic.

Capacity.—To evaporate three pounds water from 100° and 70 pounds pressure (M. E. unit) per square foot of heating surface. In other words, 10 square feet of heating surface per horse-power.

Economy.—To evaporate nine pounds of water from 120° F. at temperature corresponding to 160 steam pressure per pound of good Scranton anthracite pea coal when developing its rated capacity.

Quality of Steam.—The steam furnished by boiler when developing its rated capacity shall not exceed 2½ per cent. of moisture as determined by calorimeter.

Furnaces.—To be of either the corrugated or Adamson type, having a common combustion chamber.

Riveting.—Longitudinal seams of shell to be butt jointed and double butt strapped and triple riveted each side of butt. Circumferential seams to be double riveted. Flanges and heads to be single riveted. All holes to be drilled when sheets are in position for riveting.

Staying.—Boiler to be stayed in the most approved manner to withstand 160 pounds working pressure. Strains on welded braces must not exceed 6,000 pounds per square inch section. Solid stays must not have strains to exceed 9,000 pounds per square inch of section. All stays, braces and rivets to be of the best double refined iron.

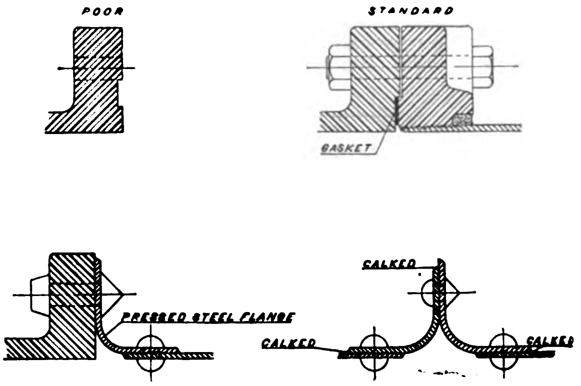
Manholes and Handholes.—Each boiler to have at least four manholes to facilitate cleaning as well as a sufficient number of handholes for the same purpose.

Plates.—All plates to be of the best marine steel of 60,000 pounds tensile strength.

Fronts.—Each boiler to be supplied with neatly designed furnace fronts and cast iron bridge walls.

Fixtures.—Each boiler to be supplied with necessary supporting lugs or saddles, one set of grate bars for each furnace, all necessary dampers, flue and cleaning doors and frames.

Fittings.—Each boiler to be supplied with pop safety valve, steam gauge, water column, gauge cocks and stand pipe, asbestos blow-off cock, stop and swinging check valves and necessary flanges for steam pipe connections riveted to boilers.



FIGS. 5, 6, 7 AND 8.

General Conditions.—Boiler to be set to return the gases to the front underneath the bottom of the boiler. All material and workmanship to be first-class in every respect and certificate of test and inspection furnished.

Remarks.—That the type of boiler here specified has demonstrated its ability to perform its work is unquestioned; not only under the pressure specified and called for in electric service, but even the higher pressures used in the merchant marine to-day; taken in connection with its ability to work under high pressures successfully, it has good average economy. The other point that makes it most fitted for the service mentioned is the small space occupied, together with its enormous capacity or ability to furnish almost any amount of steam when forced, and this, too, of good quality as regards percentage of moisture. This, however, is easily accounted for by the large liberating surface at the water line. The firing of the boiler internally is another advantage offered by this type of boiler, when contrasted with the repairs necessary to furnaces, boiler settings, etc.

PIPING.

Piping is a part of the power station which, in the minds of many people, does not require much attention. We believe, however, that it is one which should receive the most careful and earnest attention of the constructing engineer. The safety, good working and reliability of a power station is dependent on the piping as much as any other factor in its outlay. We have tried to generally outline here, under the head of "piping," a few thoughts and suggestions which are supplemented by some sketches of what has been our practical experience of the requirements in this line.

PIPING SPECIFICATIONS.

This sketch, Figs. 5 and 6, shows a type of joint at flange on pipe to fittings or valves. The flanges are recessed, male and female, for gasket, to prevent the "blowing out" of the same. This effect is considerable if the gasket is thick. The flange is screwed on the pipe and then calked in on the inside. The small recess in the back of the flange around the body of the pipe is to be filled and calked with babbitt or steam metal in case of leakage of screw joint when circumstances will not permit, for the time being, to break the joint and recalk the pipe itself. The threads on the pipe should be cut by the same person, chasing the threads on flanges so as to secure the same taper on both; a very essential condition to a tight job. The screw joint should be made up in plumbago, to be removed, if necessary, at a future time without breaking. The flange should be designed to be equally strong through bolt holes as any other part of the flange. This is easily done by means of bosses about bolts.

There is one thing that should be remembered in the design of cast iron flanges, and that is, that it is hardly possible to get them too heavy for the work. The initial strain due to screwing them on the pipe is so large that the factor of safety that remains is not usually sufficient to withstand the higher steam pressure, together with the increased expansive strains due to the increased temperature at the higher pressure. The weak point in the theory of cast iron flanges is as follows:

Conceive the flange to be made up of laminæ in the form of concentric circles. In case the first lamina is strained beyond its ultimate strength by screwing up, then although no disastrous results will be detected immediately the life of the flange will be very short, and it will fail by cracking, commencing nearest the threads, *i. e.*, at its smallest diameter, and gradually radiating outward. This theory is similar to the one used in the design of hydraulic cylinders, and is equally applicable so far as screwing up the flanges is concerned. From this, one can see that it is possible to screw up a flange too tight; a fact too often overlooked in the anxiety to get a tight job, and usually done when the threaded work is poor.

Gaskets.—Copper corrugated gaskets are all right in the case of mains, where the joints are made up with the ends of the pipe free to move; in fact, they could be omitted altogether in such a case, and the joint made iron to iron; but there is the practical consideration that in case of repairs (and that time is sure to come) the line will be always distorted from its original position; *i. e.*, it will have initial strains, due to some part of it having steam on to run a portion of plant; and when the joint is broken for repairs, it is possible to bring the flanges back in the same relative position they previously occupied, and for this reason alone, I prefer the use of a wire insertion rubber gasket of very thin material, say not over $\frac{1}{16}$ inch thick. This will make up, or rather allow, for this slight inequality of the flange facings, and permit a tight job to be made where a copper gasket or iron to iron would leak.

Another type of connection for high pressure is shown in Figs. 7 and 8. The weak point in these designs is the fact that all calking is done from the outside at the joint, and that it makes a series of small traps for water of condensation. The system would give more trouble after it once commenced to leak than the one mentioned. The use of steel is good practice, and by making such a system with long radius bends of the pipe itself, would give good satisfaction.

Expansion Joints.—The average slip joint will not answer at all for high pressure, for when the packing is adjusted sufficiently tight to prevent leaking, it will also be sufficiently tight to keep the joints from moving to take up the expansion, and if loose enough for this, it will be found to leak.

The corrugated copper expansion joint offers a solution to the difficulty of expansion joints, but when made as most of them are to-day in this country they almost defeat the object they seek to attain. The corrugations in these joints are made literally like the threads of a screw, whereas they should be made without longitudinal pitch, so as to prevent any torsional action tending to make them rigid. Probably the best way to take up the expansion in a high pressure system is by means of long pipe bends of easy radius and with all branches so located, and of sufficient length to take any expansion of the mains by means of their flexibility on account of their small size. Judicious arrangement of this sort can be made without the use of any expansion joints whatever. Under restricted and peculiar conditions copper bends with iron bands can be used with good effect, if commercial considerations are notprohibitive.

Pipe.—Wrought iron or steel lap welded pipe will answer most conditions successfully, even in case of long bends or elbows made from this material. The tests should be rigid to avoid defective seams caused by bending. Extra heavy pipe will not be found necessary.

Fittings.—These should be of the best charcoal iron, true to pattern and of workmanlike finish. The flanges should be ribbed in preference to being thickened up, on account of shrinkage strains in metal.

Valves.—There should be gate valves, operated by an outside screw. The spindle should be of steel, and tinned. The body should be extra heavy and ribbed to prevent any springing, which would cause the valve to leak around the seats when closed. The valve body should be stiffer than other part of the system in order to have all the valves tight. The seats of valves should be bronze or brass, and able to withstand the high temperatures of the high steam pressures, as well as very non-corrodible.

All valves over seven inches diameter of port should have a by-pass valve (a smaller valve about 1½ to 2⅛ inches in diameter) of exactly similar type, so that the pressures can be equalized on both sides of the large valve before it is opened by means of the smaller one. This relieves the excessive strain on the spindles and seats, and should always be used on high pressure work.

Support.—A high pressure steam pipe should always be supported, when possible, from underneath, by means of some solid mass, so that its weight would rest directly upon this support. This method, when it is possible to follow it, will be found to eliminate that vibration so often noticed, and the result of which is leaky joints caused by the racking and straining of the whole piping system. When the suspension method is used there are always one or two points which, if held firmly, will stop the vibration of the whole system. Other positions will cause a general leakage. Experiment will determine these points. Piping should be rigidly secured by proper means.

Bolts.—All bolts should be of double refined iron or low grade steel. Their weakest point is directly under the head, and a good test is to place one in a vise, holding it by the head and bending the shank over by means of blows from a hammer. A good bolt should stand this without showing any cracks whatever at the head. Both head and nut should be hexagonal on account of the limited space in which it is often necessary to use a wrench. The whole system of piping should be blown out thoroughly with steam before the engine connections are made, to prevent any chips or dirt from being carried through to the cylinders.

GENERATORS.

In describing the type of generator required, it is necessary to be more specific as to the class of work it is required to perform, and particularly as regards the voltage, etc., than in our other departments. We will therefore in the main describe, as far as concerns the generator and switchboard, apparatus especially adapted for railway power service.

Generators for electric railway service should be constructed with a view to efficient handling of variable loads and excessive overloads for short periods. They should be mounted on a brick foundation set on a bed of concrete. The top of masonry should be provided with a wooden foundation base; this wooden base to be built up of two layers of timber, with tar paper or some good insulating material between the layers, the first layer bolted by means of foundation bolts direct to masonry, the upper layer being bolted to the lower layer, thus assuring good insulation between the iron foundation frame of generator and the ground. This precaution is taken with a view of protecting the generator from lightning coming in over the line.

Generator Frame in Belted Type.—The foundation frame of the generator should be bolted directly to the wooden cap of the foundation and provided with grooves and sliding arrangement for tightening the belt. The general design of frame and magnets in the latest type of generators of large capacity is a circular casting built up of two or more parts and concentric with the shaft of the machine. The pole-pieces are in many cases made of laminated iron cast direct into this frame; the field wire, both shunt and series, being wound on adjustable spools, which, by suitable flanges and clamps, are bolted direct to the frame when slipped over pole-pieces. The compound field of the machine should provide for sufficient fall in potential due to loss in armature at variable loads, and to maintain a constant E. M. F. at the switchboard. The practice of over-compounding a machine so as to obtain an increased E. M. F. with increased load—in some cases 10 per cent.—is not a good method where a number of generators are in operation, for the following reason:

The machines over-compound in proportion to the load on themselves, and not in proportion to the load on any individual feeder, the result being that if, for instance, two machines are running under condition of full load and have increased E. M. F. 10 per cent. at the switchboard, they may be feeding into two feeders; one feeder which is considerably overloaded, and the other which is very lightly loaded. The result is that the lightly loaded feeder is supplied with a high E. M. F., higher than necessary, and the overloaded feeder is the only one benefited. When a third machine is thrown into this combination the E. M. F. is reduced, as the load is then divided between three machines instead of one, and consequently the overloaded feeder is not assisted to the extent to which it was before.

A better method in large installations is to provide an auxiliary bus which can be connected at any time with any one or more generators, this auxiliary bus to be run at a higher E. M. F., say at 575 volts to 600, and run in connection with it the heavily loaded feeders, or those feeders which are of much greater length than the average of the system. This method reduces the quantity of wire required to run a system and maintain a fairly uniform pressure over the different lines. Arrangements should be made on the switchboard so that any feeder or any generator may be connected to or disconnected from this auxiliary bus, or to or from the main bus, the main bus to be run with an E. M. F. of 500 volts, the same as in ordinary practice. In other words, this divides the switchboard up into two distinct arrangements, electrically separated from each other. This has been tried in practice and has proved very satisfactory.

To return to the construction of the generator, the armature of the machine should be run in self-oiling bearings, made with adjustable globe seats, so as to insure perfect alignment, and provided in the larger sized machine with outboard bearing at the pulley end of the shaft.

The commutator should be of ample width to insure good contact surface between commutator and brushes, for a 500-volt machine. Carbon brushes have proved very satisfactory, and are almost universally used at the present time. The machine should be so constructed that the brushes should not need readjustment for any change of load from zero to 25 per cent. overload. There should be practically no sparking at the points of contact. The generator should be provided with a double pole switch, so as to enable the operator to disconnect the generator entirely from the system when it is required to do repairs, overhaul the machine or shut it down.

The generators should be capable of developing their normal output for a continuous run, and also capable of developing at least 25 per cent. above their normal capacity for short periods without undue heating of any part of the armature, bearings or fields.

There are several methods of connecting the generators with the switchboard.

The three wires from the machine, namely, the positive, negative and equalizing wires are all carried direct to a three pole switch; the equalizing wire is connected to an equalizing bus, and the ground wire to ground bus. The line wire of the machine from the switch is connected to an ampere meter and also to an automatic cut-out, and from there to the main bus. If an auxiliary bus is used the wire, instead of being connected directly to bus, is connected from the automatic cut-out to a transfer switch, which enables the wire to be connected through to auxiliary or the main bus. The main bus is in connection with a main ampere meter, the other terminal of the ampere meter being connected directly to the feeder bus. The feed wires are brought in the station to the switchboard and attached to a single pole switch; from this to an ampere meter, then through an automatic cut-out; then to the feeder bus, each feeder being provided with a lightning arrester. The line wire from the machine above described should be taken from the series field side of the machine, as this series winding affords a very good protectioon from lightning coming in over the line, acting as a very efficient "kicker coil." The ground bus should be connected direct to the rails near the station and also to a suitable ground bus within the station.

To insure an equalization of load between the various generators all the dynamo mains of the same potential should be of equal resistance, provided the machines are of equal capacity, and have a resistance inversely proportionate to their capacity, if of unequal capacity. The usual method followed is to calculate the size of the mains required for the generator farthest from the switchboard; then make the generator mains of the other machines of the same length as this, using the same size wire. In other words, all the positive mains will be of equal resistance, all the negative mains will be of equal resistance, and all the equalizing mains will be equal. It is not necessary to make the equalizing mains of any larger carrying capacity than the others.

Great care should be exercised in making joints between the different instruments and mains, to insure good conductivity, as a poor joint will throw the most careful calculations out. The usual method adopted now for making joints is to use a mechanical clamp having the contact surfaces perfectly clean and of ample surface contact. In operating the switchboard, care should be taken that all instruments required to be used to throw a generator in or out of line should be so arranged that the operator is not required to leave his position at the switch controlling the generator at the board. To obtain this result the voltmeter may be arranged on a carriage which can travel along the length of the board and make automatic connection to any generator as it reaches a position exactly opposite the instruments connected with that generator. By suitable arrangement the voltmeter can be switched, when in position, with the feeder bus, and also with the generator which it is to test, so that without moving the instruments, pressure of the line or pressure of the machine may be taken and the machine brought up to the same electromotive force as that of the line before being connected into service. The automatic regulators on the generator should be adjusted to cut out the generator when the overload of the machine is more than it will safely carry even for short periods. The automatic regulators on the feeders should be adjusted for an excessive overload on that feeder, as in many cases of railway service the feeder is subjected to excessive overloads for very short periods, and it is a source of very great inconvenience to have an automatic regulator continually cutting out the line on overloads of very short duration.

The latest types of switchboards are built up of fire proof material perfectly incombustible. The framework may be built up of iron pipe or of angle iron, and if located near the wall it should be set up at least 20 to 24 inches from the wall, and iron braces from top of frame anchoring into the wall. The general design of this frame is dependent entirely upon the number of instruments and their location on the board, as care must be taken that, with the present method of back connections on the instruments, the cross bars of the frame do not interfere in any way with the bare wire coming through back connections, and should be a safe distance to prevent any danger from grounds. To this iron frame should be securely bolted large slabs of marbleized slate or white marble. Asbestos cloth or other cushioning device should be interposed between the slate and the contact points of the iron frame, so that the slate slabs may be securely fastened without risk of breakage. If slate is used, it should be carefully tested after all holes are drilled, to insure perfect insulation. All instruments to be used on the board should then be connected directly to the slate slabs and not set on independent sub-bases unless absolutely necessary. As before mentioned, all connections on instruments should be made from the back of the board and no wiring exposed from the front. At the same time, all connections and wire should be so located as to be easily accessible for repairs or inspection. Where wires are passed through the floor below the switchboard, the holes should be fitted with a floor insulator of hard rubber made water tight so that the floor beneath the switchboard may be kept perfectly clean, and if any water accumulates, it shall not be able to follow the wire down through the floor.

In addition to the foregoing arrangement of the switchboard, the following plan may be used: Instead of running three wires directly from each generator to a three-hole switch on the switchboard, take the equalizing wire from each machine and run to a common point, using a short bus, or any method of connecting which may be deemed most practical; so that all equalizing wires shall be of equal resistance to this point. Then take the ground main from the generator and run directly to the ground bus. The line main from the generator is then taken directly to the switchboard and connected to a single pole switch. From this switch connections will be made similar to the board already described. This arrangement provides a switchboard in which all wires are of the same polarity, and it insures a very safe method of operating. The only objection to this is that it is impossible to cut out the machine entirely from the switchboard, and it is therefore advisable in using this method to have each generator equipped with a double pole switch attached directly to the generator controlling both lines.

Regarding the grounding of positive or negative wire, a great variety of opinion is expressed by engineers as to the better method; some advising the grounding of positive, and others the neutral wire, the result which it is desired to obtain being a condition which will produce the least electrolytic action at contact points in the ground return, such as bond wires, supplementary, etc.

We have tried to outline in general here the important factors for consideration in an ideal central power station; our desire being more to lead up to a general line of thought or discussion on the matter, and point out some of the most desirable features in relation thereto. If we have accomplished this, our purpose has been fulfilled.

Trusting the matter will meet with your earnest and careful consideration and free discussion, it is very respectfully submitted.

SIR JOHN PENDER AND JAY GOULD.

A WRITER in the Sunday *Recorder* tells the following interesting story about the visit of Sir John Pender to this country in the early eighties.

"There was some talk in financial and other circles at the time of Mr. Pender going into the Western Union directory, and I believe he did go in. Mr. Pender had been away out on the plains, and, the special car in which he traveled having been hauled up at a "siding," the telegraph office of the Western Union Company was entered to get the news. "I was then informed," said Mr. Pender, "of the great victory of our troops in Egypt under Gen. Wolseley. I got news of the success, taking American time as the standard, ahead of the hour when the battle had been fought, and I wired Gen. Wolseley my congratulations to Egypt from the midst of the American wilderness." "The fact," said Mr. Pender, "that, through human agency, that feat was possible of accomplishment, that in my case it had been accomplished, made a deeper impression upon my mind than I can describe to you. It was a miracle of human progress."

The incident naturally suggested the name of Mr. Gould, and to Mr. Pender I put the question, "What is your estimate of Mr. Gould?" The papers had told me that they had met.

"Mr. Gould," said Mr. Pender, "is the ablest, the most sagacious, the most far-seeing man I have ever met."

"Ten minutes after Mr. Pender had spoken these words I saw Mr. Gould walking down Broadway along by Trinity church. Crossing over from the head of Wall street we met near the main entrance of the building. He stopped and I opened the conversation in these words: "Mr. Gould, a few minutes ago I was with the Cable King of the old world, and now I meet the Telegraph King of the new one."

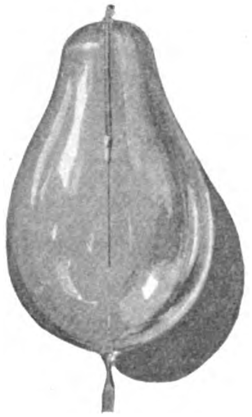
"You mean Mr. Pender," he answered, with the faintest perceptible smile.

"Yes," I replied, "and in the course of an hour's chat with him he spoke about you."

"Mr. Gould became at once interested, and said: "Well, what did he say?" I repeated the words above quoted. He looked in at the tomb of Lawrence of "never give up the ship" fame just inside the church railings. Two o'clock in the afternoon; Broadway was thronged. Looking up suddenly, he saw that fifteen or twenty people had stopped to look at him. His pallid face flushed a little, and he said: "Will you walk down to the office with me?" It was only a few steps away. I then told him about the Wolseley incident, and what Mr. Pender had said of Western Union, which seemed to gratify him very much."

ALTERNATE CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY.[1]—I.

BY NIKOLA TESLA.



AT the first outset this investigation was taken up with the view of studying the effects of rapidly changing electrostatic and electromagnetic stresses. It was thought, from theoretical considerations, that some useful observations would be made in following up this line of experiment by means of properly constructed apparatus; but the anticipations were by far surpassed, for a number of unexpected phenomena were noted, and some novel facts brought to light, which have opened up a new and promising field of research. Some of the results obtained are of special interest on account of their direct bearing upon the problem of producing an efficient illuminant.

The phenomena which are due to the changing character of the stresses are exalted when the time rate of change is increased, hence the study of these phenomena is much facilitated by the employment of apparatus adapted especially for the purpose of carrying on such investigations. With this object in view, several types of alternators were constructed, capable of giving currents of frequencies from 5 to 10,000 and even more. Currents of much higher frequencies used in some of these experiments, were obtained by disruptively discharging condensers.

The construction of the alternators offered at first great difficulties. To obtain these frequencies it was necessary to provide several hundred polar projections, which were necessarily small and offered many drawbacks, and this the more, as exceedingly high peripheral speeds had to be resorted to. In some of the first machines both armature and field had polar projections. These machines produced a curious noise, especially when the armature was started from the state of rest, the field being charged. The most efficient machine was found to be one with a drum armature, the iron body of which consisted of very thin wire annealed with special care. It was, of course, desirable to avoid the employment of iron in the armature, and several machines of this kind, with moving or stationary conductors were constructed, but the results obtained were not quite satisfactory, on account of the great mechanical and other difficulties encountered.

The study of the properties of the high frequency currents obtained from these machines is very interesting, as nearly every experiment discloses something new. Two coils traversed by such a current attract or repel each other with a force which, owing to the imperfection of our sense of touch, seems continuous. An observation, scarcely foreseen, is that a piece of iron, surrounded by a coil through which the current is passing appears to be continuously magnetized. This apparent continuity might be ascribed to the deficiency of the sense of touch, but there is evidence that in currents of such high frequencies one of the impulses preponderates over the other. As might be expected, conductors traversed by such currents are rapidly heated, owing to the increase of the resistance, and the heating effects are relatively much greater in the iron.

The hysteresis losses in iron are so great that an iron core, even if finely subdivided, is heated in an incredibly short time. To give an idea, an ordinary iron wire of $\frac{1}{16}$ inch in diameter inserted within a coil having 250 turns, with a current estimated to be five amperes passing through the coil, becomes within two seconds' time so hot as to scorch wood. Beyond a certain frequency, an iron core, no matter how finely subdivided, exercises a dampening effect, and it was easy to find a point at which the impedance of a coil was not affected by the presence of a core consisting of a bundle of very thin well annealed and varnished iron wires.

---

[1] A lecture delivered before The Royal Institution of Great Britain, Thursday, February 4, 1892. Author's abstract in Transactions.

Experiments with a telephone, a conductor in a strong magnetic field, or with a condenser or arc, seem to afford certain proof that sounds far above the usually accepted limit of hearing would be perceived if produced with sufficient power.

The arc produced by these currents possesses several interesting features. Usually it emits a note the pitch of which corresponds to twice the frequency of the current, but if the frequency be sufficiently high it becomes noiseless, the limit of audition being determined principally by the linear dimensions of the arc. A curious feature of the arc is its persistency, which is due partly to the inability of the gaseous column to cool and increase considerably in resistance, as in the case with low frequencies, and partly to the tendency of such a high frequency machine to maintain a constant current.

In connection with these machines the condenser affords a particularly interesting study. Striking effects are produced by proper adjustments of capacity and self-induction. It is easy to raise the E. M. F. of the machine to many times the original value by simply adjusting the capacity of a condenser connected in the induced circuit. If the condenser be at some distance from the machine, the difference of potential on the terminals of the latter may be only a small fraction of that on the condenser.

But the most interesting experiences are made when the tension of the currents from the machine is raised by means of an induction coil. In consequence of the enormous rate of change obtainable in the primary current, much higher potential differences are obtained than with coils operated in the usual ways, and, owing to the high frequency, the secondary discharge possesses many striking peculiarities. Both the electrodes behave generally alike, though it appears from some observations that one current impulse preponderates over the other, as before mentioned.

The physiological effects of the high tension discharge are found to be so small that the shock of the coil can be supported without any inconvenience, except perhaps a small burn produced by the discharge upon approaching the hand to one of the terminals. The decidedly smaller physiological effects of these currents are thought to be due either to a different distribution through the body or to the tissues acting as condensers. But in the case of an induction coil with great many turns the harmlessness is principally due to the fact that but little energy is available in the external circuit when the same is closed through the experimenter's body, on account of the great impedance of the coil.

In varying the frequency and strength of the currents through the primary of the coil, the character of the secondary discharge is greatly varied, and no less than five distinct forms are observed:—weak, sensitive thread discharge, a powerful flaming discharge, and three forms of brush or streaming discharges. Each of these possesses certain noteworthy features, but the most interesting to study are the latter. Under certain conditions the streams, which are presumably due to the violent agitation of the air molecules, issue freely from all points of the coil, even through a thick insulation. If there is the smallest air space between the primary and secondary, they will form there and surely injure the coil by slowly warming the insulation. As they form even with ordinary frequencies when the potential is excessive, the air-space must be most carefully avoided.

These high frequency streamers differ in aspect and properties from those produced by a static machine. The wind produced by them is small and should altogether cease if still considerably higher frequencies could be obtained. A peculiarity is that they issue as freely from surfaces as from points. Owing to this, a metallic vane, mounted in one of the terminals of the coil so as to rotate freely, and having one of its sides covered with insulation, is spun rapidly around. Such a vane would not rotate with a steady potential, but with a high-frequency coil it will spin, even if it be entirely covered with insulation, provided the insulation on one side be either thicker or of a higher specific inductive capacity. A Crookes electric radiometer is also spun around when connected to one of the terminals of the coil, but only at very high exhaustion or at ordinary pressures.

There is still another and more striking peculiarity of such a high frequency steamer, namely, it is hot. The heat is easily perceptible with frequencies of about 10,000, even if the potential is not excessively high. The heating effect is, of course, due to the molecular impacts and collisions. Could the frequency and potential be pushed far enough, then a brush could be produced resembling in every particular a flame and giving light and heat, yet without a chemical process taking place. The hot brush, when properly produced, resembles a jet of burning gas escaping under great pressure, and it emits an extraordinary strong smell of ozone. The great ozonizing action is ascribed to the fact that the agitation of the molecules of the air is more violent in such a brush than in the ordinary streamer of a static machine.

But the most powerful brush discharges were produced by employing currents of much higher frequencies than it was possible to obtain by means of the alternators. These currents were obtained by disruptively discharging a condenser and setting up oscillations. In this manner currents of a frequency of several hundred thousand were obtained. Currents of this kind produce striking effects. At these frequencies, the impedance of a copper bar is so great that a potential difference of several hundred volts can be maintained between two points of a short and thick bar, and it is possible to keep an ordinary incandescent lamp burning at full candle power by attaching the terminals of the lamp to two points of the bar no more than a few inches apart. When the frequency is extremely high, nodes are found to exist on such a bar, and it is easy to locate them by means of a lamp.

By converting the high-tension discharges of a low-frequency coil in this manner, it was found practicable to keep a few lamps burning on the ordinary circuit in the laboratory, and by bringing the undulation to a low pitch, it was possible to operate small motors. This plan likewise allows of converting high-tension discharges of one direction into low tension unidirectional currents, by adjusting the circuit so that there are no oscillations. In passing the oscillating discharges through the primary of a specially-constructed coil, it is easy to obtain enormous potential differences with only few turns of the secondary.

Great difficulties were at the beginning experienced in producing a successful coil on this plan. It was found necessary to keep all air, or gaseous matter in general, away from the charged surfaces, and oil immersion was resorted to. The wires used were heavily covered with gutta-percha and wound in oil, or the air was pumped out by means of a Sprengel pump.

The general arrangement was the following: An ordinary induction coil, operated from a low-frequency alternator, was used to charge Leyden jars. The jars were made to discharge over a single or multiple gap through the primary of the second coil. To insure the action of the gap, the arc was blown out by a magnet or air-blast. To adjust the potential in the secondary a small oil condenser was used, or polished brass spheres of different sizes were screwed on the terminals and their distance adjusted.

When the conditions were carefully determined to suit each experiment, magnificent effects were obtained.

Two wires, stretched through the room, each being connected to one of the terminals of the coil, emit streams so powerful that the light from them allows distinguishing the objects in the room; the wires become luminous even if covered with thick and most excellent insulation. When two straight wires, or two concentric circles of wire, are connected to the terminals, and set at the proper distance, a uniform luminous sheet is produced between them. It was possible in this way to cover an area of more than one meter square completely with the streams. By attaching to one terminal a large circle of wire and to the other terminal a small sphere, the streams are focused upon the sphere, produce a strongly lighted spot upon the same, and present the appearance of a luminous cone. A very thin wire glued upon a plate of hard rubber of great thickness, on the opposite side of which is fastened a tinfoil coating, is rendered intensely luminous when the coating is connected to the other terminal of the coil. Such an experiment can be performed also with low frequency currents, but much less satisfactorily.

When the terminals of such a coil, even of a very small one, are separated by a rubber or glass plate, the discharge spreads over the plate in the form of streams, threads, or brilliant sparks, and affords a magnificent display, which cannot be equalled by the largest coil operated in the usual ways. By a simple adjustment it is possible to produce with the coil a succession of brilliant sparks, exactly like with a Holtz machine.

Under certain conditions, when the frequency of the oscillation is very great, white phantom-like streams are seen to break forth from the terminals of the coil. The chief interesting feature about them is, that they stream freely against the outstretched hand or other conducting object without producing any sensation, and the hand may be approached very near to the terminal without a spark being induced to jump. This is due presumably to the fact that a considerable portion of the energy is carried away or dissipated in the streamers, and the difference of potential between the terminal and the hand is diminished.

It is found in such experiments, that the frequency of the vibration and the quickness of succession of the sparks between the knobs affect to a marked degree the appearance of the streams. When the frequency is very low, the air gives way in more or less the same manner as by a steady difference of potential, and the streams consist of distinct threads, generally mingled with thin sparks, which probably correspond to the successive discharges occurring between the knobs. But when the frequency is very high, and the arc of the discharge produces a sound which is loud and smooth (which indicates both that oscillation takes place and that the sparks succeed each other with great rapidity), then the luminous streams formed are perfectly uniform. They are generally of a purplish hue, but when the molecular vibration is increased by raising the potential they assume a white color.

The luminous intensity of the streams increases rapidly when the potential is increased; and with frequencies of only a few hundred thousand, could the coil be made to withstand a sufficiently high potential difference, there is no doubt that the space around a wire could be made to emit a strong light, merely by the agitation of the molecules of the air at ordinary pressure.

Such discharges of very high frequency which render luminous the air at ordinary pressure we have very likely occasion to witness in the aurora borealis. From many of these experiments it seems reasonable to infer that sudden cosmic disturbances, such as eruptions on the sun, set the electrostatic charge of the earth in an extremely rapid vibration, and produce the glow by the violent agitation of the air in the upper and even in the lower strata. It is thought that if the frequency were low, or even more so if the charge were not at all vibrating, the lower, dense strata would break down as in a lightning discharge. Indications of such breaking down have been repeatedly observed, but they can be attributed to the fundamental disturbances, which are few in number, for the superimposed vibration would be so rapid as to not allow a disruptive break.

The study of these discharge phenomena has led to the recognition of some important facts. It was found that gaseous matter must be most carefully excluded from any dielectric which is subjected to great, rapidly-changing electrostatic stresses. Since it is difficult to exclude the gas perfectly when solid insulators are used, it is necessary to resort to liquid dielectrics. When a solid dielectric is used, it matters little how thick and how good it is; if air be present streamers form, which gradually heat the dielectric and impair its insulating power, and the discharge finally breaks through. Under ordinary conditions the best insulators are those which possess the highest specific inductive capacity, but such insulators are not the best to employ when working with these high frequency currents, for in most cases the higher specific inductive capacity is rather a disadvantage. The prime quality of the insulating medium for these currents is continuity. For this reason principally it is necessary to employ liquid insulators, such as oils. If two metal plates, connected to the terminals of the coil, are immersed in oil and set a distance apart, the coil may be kept working for any length of time without a break occurring, or without the oil being warmed, but if air bubbles are introduced, they become luminous; the air molecules, by their impact against the oil, heat it, and after some time cause the insulation to give way. If, instead of the oil, a solid plate of the best dielectric, even several times thicker than the oil intervening between the metal plates, is inserted between the latter, the air having free access to the charged surfaces, the dielectric invariably is warmed and breaks down. The employment of the oil is advisable or necessary even with low frequencies, if the potentials are such that streamers form, but only in such cases, as is evident from the theory of the action. If the potentials are so low that streamers do not form, then it is even disadvantageous to employ oil, for it may, principally by confining the heat, be the cause of the breaking down of the insulation. The exclusion of gaseous matter is not only desirable on account of the safety of the apparatus, but also on account of economy, especially in a condenser, in which considerable waste of power may occur merely owing to the presence of air, if the electric density on the charged surfaces is great.

In the course of these investigations a phenomenon of special scientific interest has been observed. It may be ranked among the brush phenomena, in fact it is a kind of brush which forms at, or near, a single terminal in high vacuum. In a bulb with a conducting electrode, even if the latter be of aluminum, the brush has only a very short existence, but it can be preserved for a considerable length of time in a bulb devoid of any conducting electrode. To observe the phenomenon it is found best to employ a large spherical bulb having in its centre a small bulb supported on a tube sealed to the neck of the former. The large bulb being exhausted to a high degree, and the inside of the small bulb being connected to one of the terminals of the coil, under certain conditions there appears a misty haze around the small bulb, which, after passing through some stages, assumes the form of a brush, generally at right angles to the tube supporting the small bulb. When the brush assumes this form it may be brought to a state of extreme sensitiveness to electrostatic and magnetic influence. The bulb hanging straight down, and all objects being remote from it, the approach of the observer within a few paces will cause the brush to fly to the opposite side, and if he walks around the bulb it will always keep on the opposite side. It may begin to spin around the terminal long before it reaches that sensitive stage. When it begins to turn around, principally, but also before, it is affected by a magnet, and at a certain stage it is susceptible to magnetic influence to an astonishing degree. A small permanent magnet, with its poles at a distance of no more than two centimetres, will affect it visibly at a distance of two metres, slowing down or accelerating the rotation according to how it is held relatively to the brush.

When the bulb hangs with the globe down, the rotation is always clockwise. In the southern hemisphere it would occur in the opposite direction and on the (magnetic) equator the brush should not turn at all. The rotation may be reversed by a magnet kept at some distance. The brush rotates best, seemingly, when it is at right angles to the lines of force of the earth. It very likely rotates, when at its maximum speed, in synchronism with the alternations, say 10,000 times a second. The rotation can be slowed down or accelerated by the approach or receding of the observer, or any conducting body, but it cannot be reversed by putting the bulb in any position. Very curious experiments may be performed with the brush when in its most sensitive state. For instance, the brush resting in one position, the experimenter may, by selecting a proper position, approach the hand at a certain considerable distance to the bulb, and he may cause the brush to pass off by merely stiffening the muscles of the arm, the mere change of configuration of the arm and imperceptible displacement being sufficient to disturb the delicate balance. When it begins to rotate slowly, and the hands are held at a proper distance, it is impossible to make the slightest motion without producing a visible effect upon the brush. A metal plate connected to the other terminal of the coil affects it at a great distance, slowing down the rotation often to one turn a second.

It is hoped that this phenomenon will prove a valuable aid in the investigation of the nature of the forces acting in an electrostatic or magnetic field. If there is any motion which is measurable going on in the space, such a brush would be apt to reveal it. It is, so to speak, a beam of light, frictionless, devoid of inertia. On account of its marvellous sensitiveness to electrostatic or magnetic disturbances it may be the means of sending signals through submarine cables with any speed, and even of transmitting intelligence at a distance without wires.

LETTERS TO THE EDITOR.

THE DRIFTLESS BALLISTIC GALVANOMETER.

In a communication appearing in your issue of Dec. 21, 1892, under the above heading, Messrs. Nalder Bros. & Co. have made the statement with reference to an instrument described by me in an article in The Electrical Engineer, of Nov. 16, that "the whole general plan is a barefaced copy of our ballistic galvanometer described," etc. Language so much more exact than courteous demands equally exact reply. The statement made is utterly and entirely false; inspection of the two illustrations and descriptions can not lead to any other conclusion, Messrs. Nalder Bros. & Co.'s opinion to the contrary notwithstanding. I can only assume from the fact that Messrs. Nalder Bros. & Co. themselves invite such comparison that they have trusted to the almost universal preference of people to accept a statement on faith rather than take the trouble to verify it, since I am sure that they are not so inexperienced in instrument construction as to call two instruments *alike* because each has a base and three leveling screws.

Far from being alarmed by this "deadly parallel," nothing would afford me greater satisfaction than to have these two illustrations printed side by side, as Messrs. Nalder Bros. & Co. suggest. Having some faith in my own performances I find that I am usually only too willing to make comparisons and I shall certainly not refuse the present opportunity so kindly offered.

Comparing the two engravings, then, in the first place, each instrument has a round base, two coils, a metal case and a system consisting of four bell magnets. In the Nalder instrument the case is exactly the same as the case shown on page 287 of Ayrton's *Practical Electricity* as applied to a Thomson galvanometer even to the symmetrical placing of the two binding posts which pass through the case to make contact with the coil terminals. This same case may be seen again on page 18 of Paterson & Cooper's 1890 catalogue of "Electrical Measuring Instruments;" also in Elliott Bros.' catalogues for ten years back on the "round brass pattern" of Thomson galvanometer. This case, as made by Nalder Bros., has to be bodily lifted up and off in order that the coils may be gotten at; it is also necessary to unscrew both binding posts each time the system is to be reached. As the case carries part of the controlling system the control of the needle will be altered each time the case is disturbed. It is, hence, impossible to adjust nicely the instrument, since if the case is off we cannot get a suitable "control," and if on, we cannot get to the system.

The case of my instrument is made in two halves, the front half swinging forward so as to expose the coils; but one binding post must be taken out to accomplish this and the "control" is not altered in the least. The coils are mounted, in my instrument, on two corrugated rubber pillars instead of four plain ones; taking account of the corrugation the insulation resistance of my instrument is four times that of the Nalder. The coil frames of the Nalder are made differently from mine; though they swing away from one another they are not interchangeable as mine are. Also in my instrument it is possible to connect the two coils in any desired way either in series, multiple or differentially; or either coil may be used singly. Thus a 1,000 ohm galvanometer may be converted, besides, into a 500 or a 250 ohm instrument or a 250 ohm differential. In the Nalder the coils can only be used in series.

The magnetic system is very like the Nalder system; it is, however, one of the usual forms of Thomson system with bell magnets substituted for flat ones; moreover it is exactly like several made by Queen & Co., several years since for the United States Government, save that in the latter a sphere was used instead of two bell magnets in the centre and that the improved "non-drifting" device was not attached. If there is any creditable originality in the use of four bell magnets related to one another as I have them in my instument I cheerfully yield it all to Messrs. Nalder Bros. & Co. with an apology for ever having unconsciously endeavored to retain it; had I been aware that they considered their reputation to rest upon so slender a basis I should certainly have been more particular about these small points.

To continue and to be brief: The little magnet upon the case and the "tail magnet" seen upon the Nalder galvanometer are *not* seen in mine. I gave them a trial and gave them up because they would not either theoretically or practically perform their function. This fact might tend to render one charge of giving credit to any one before first ascertaining their wishes, since, if I remember aright, Messrs. Nalder Bros. & Co. kindly ascribed this improvement (?) to Dr. Mullineux Walmsley who, however, repudiated it a few weeks later in a letter to the London *Electrician*, April 17th, 1891, page 740. The control in my galvanometer is effected by an entirely different plan used, I believe, for the first time; by means of this plan a period of 1½ minutes can be easily attained without the slightest "drift." This is really the one great noteworthy feature of the instrument. The various other important differences between my instrument and the Nalder, such as the fact that the former has a divided torsion head where the latter has not; that the coils of the former are graded while those of the latter are not, etc., have so little to do with the general plan that it is not necessary to speak of them in detail.

The gratuitous slur upon the firm with which I am connected is hardly worth referring to; this manner of manifesting a loss of temper seems to be an attribute of some men as well as of children. I can imagine, too, how painful it must be to some people to bring themselves to a realization of the fact that anyone else knows anything. Some allowance must be made, also, for the natural disappointment of our British friends that the infant enterprise of American instrument making has been learning to do some pretty vigorous creeping during the last year.

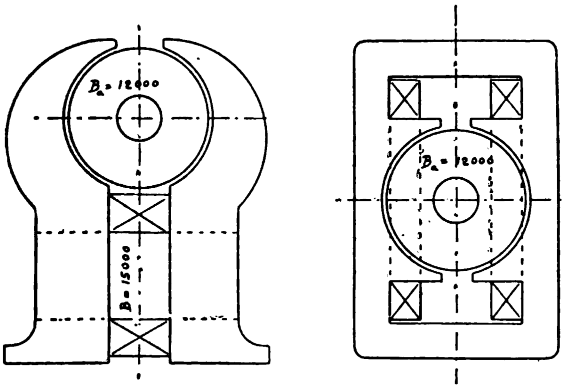
PHILADELPHIA, PA.

ELMER G. WILLYOUNG.

THE DESIGN OF THE LUNDELL MOTOR.

MY attention having been called to a letter published in THE ENGINEER of Dec. 28, 1892, headed: "The Design of the Lundell Motor," I deem it my duty to respond.

The writer of said article, a Mr. Dahl, whatever his aim may be, is evidently not aware of the fact that the mere length of wire per turn in the field coil of a dynamo or motor is not always the most important consideration. Without going into any elaborate demonstrations I will simply, for the sake of argument, call attention to two different types of motors, as shown in Figs. 1 and 2. The machine shown in Fig. 1. would be the best type of the two, according to the idea of Mr. Dahl. The induction through the field coil of this machine can be pushed as high as 15,000 lines per sq. cm. and the length of wire per turn would be quite small indeed. In the type shown in Fig. 2 the field coil surrounds part of the armature as well as a considerable air-space at both ends. With an induction of 6,000 lines per sq. cm. across the air-gap it would hardly be possible that the mean induction through the field coil could be more than 5,000 lines per sq. cm.



FIGS. 1 AND 2.

From this we see that the areas enclosed by the field coils of these two machines are as 1 to 3; or, in other words, that the length of wire per turn in the machine Fig. 2 is $\sqrt{3} = 1.73$ times that of the machine Fig. 1 (provided the coils were made of the same shape). It is unneccessary for me to show the reason why the greater length of wire per turn in machine Fig. 2 is more than compensated for by other more important gains. All electricians know this type too well and will readily acknowledge its superiority. Thus it will easily be understood that the length of wire per turn in the field coils of a dynamo or motor does not always play such an important rôle as Mr. Dahl seems to imagine.

In the motor designed by me and shown in Fig. 3, the length of wire per turn in the field coil is practically the same as in the machine Fig. 2. The construction is, however, simplified, and the resistance of the magnetic circuit made so small that the *number* of turns in field coil are reduced to a minimum, thereby making the watts expended in field less than in any other motor of the same capacity and speed.

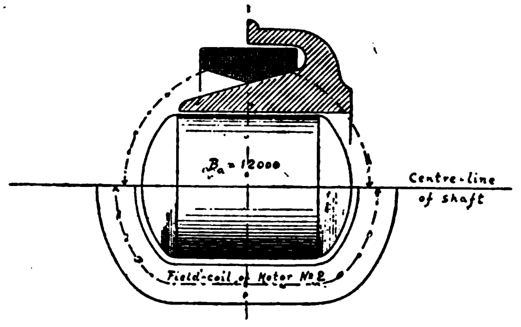


FIG. 3.

If it be true that Mr. Dahl, in 1888, constructed a motor of the type he says he had to abandon, I wish to express it as my view that the motor must have been constructed without proper knowledge of the art.

A poor design will spoil anything.

NEW YORK, Dec. 30, 1892.

ROBT. LUNDELL.

SOCIETY AND CLUB NOTES.

PREPARATIONS FOR THE ST. LOUIS ELECTRIC LIGHT CONVENTION.

SECRETARY G. F. PORTER is busily engaged making plans for the Convention of the National Electric Light Association, at the Southern Hotel, St. Louis, the last week in February. Several valuable papers have been secured including ones of greatest interest by Messrs. Blaxter, of Pittsburgh, and Sterling, of Denver; while the greatest interest is manifested by members and leading citizens in the lecture that Mr. Nikola Tesla has kindly consented to deliver, accompanied by experiments, on his high-frequency work in light and power. Mr. Porter hopes to be able to announce the full programme in a few days, after a consultation with President Ayer.

With regard to the Electric Club recently organized at St. Louis, primarily to receive and entertain the Association it may be mentioned that they have perfected their organization, received their charter and fitted up one or two very delightfully located rooms in the Equitable Building, Sixth and Locust streets, on the second floor. One room has been furnished for a general lounging, reading and reception room, in a very elegant manner, and will compare favorably with anything of the kind in the country. The room is 60 by 40 on the corner, so that it is exceptionally well ventilated and lighted. The room is steam-heated and lighted with incandescent lights. The second room will be furnished in a short time as a billiard and smoking room.

At the opening of the new year, this club has completed its organization with 90 members, which number will undoubtedly very materially increase in the near future. The electrical men of St. Louis will have no occasion to feel ashamed of the quarters to which they can introduce their colleagues from abroad during the Convention of the National Electric Light Association next February.

THE NEW YORK ELECTRICAL SOCIETY.

THE 150th meeting of the Society will take place on Jan. 11, 1893, at 8 p. m., at Columbia College, Madison avenue and Forty-ninth street.

MR. AUGUSTUS NOLL, General Superintendent of the New York Electric Equipment Company will give "A PRACTICAL TALK ON THE INSTALLATION OF ISOLATED ELECTRIC LIGHTING PLANTS," of which the following is a brief synopsis.

1. Determination of Size of Unit for Dynamo and Engine. 2. The Location of Dynamo and Engine. 3. The Construction and

Connection of Switchboards. 4. Different Systems of Wiring: (a) Feeder System: (b) Feeder and Main to Central Points; (c) The Crib System. 5. General Remarks on Wiring, Location of Lamps, Switches, etc. 6. Special Installations: Theatres, Breweries, Public Institutions, etc.

The lecturer will also illustrate the method of calculating the size of conductors required, by working out an actual example.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 73d meeting will be held at the headquarters of the institute, 12 West 31st street, Tuesday, January 17th, at 8 p. m. The paper to be presented is entitled: "Electrical Recording Meters," by Mr. Caryl D. Haskins, manager of the meter department, General Electric Co., Boston, Mass. Beginning with this meeting, the new arrangement for the publication of papers goes into effect, by which advance copies usually printed for the use of those in attendance will be made the regular mail edition of the transactions, and it is the intention that they shall reach the membership on or before the date of the meeting. Owing to the frequent delay of printed matter in the New York Post Office, those who may wish to participate in the discussion are advised to have a copy mailed at first class rate, which will be done upon application to the secretary. Members attending are requested to bring their copies with them. Gentlemen who are not identified with the institute are cordially invited to attend. The council will meet in the secretary's office at 5 o'clock.

THE PROPOSED STREET RAILWAY SUPPLY ASSOCIATION.

As chairman of the meeting held during the Cleveland, Ohio, convention, Mr. J. E. Lockwood has issued a circular giving the result of the negotiations that went on at that time, when it was decided that a supply men's association had not been shown to be necessary.

THE MAGNETIC CLUB.

The above club will hold its annual business meeting at Room 60, No. 195 Broadway, on Thursday, January 12, at 5.30 p. m., to elect officers and four members of the Governing Committee.

THE NEW LONDON, CONN., ELECTRIC CLUB.

The New London Electric Club at its last meeting listened to a paper on "Volta and His Contributions to Electrical Science." After a short discussion E. W. Burch, who has served the club faithfully as its president ever since its organization, tendered his resignation. J. R. Troland, the treasurer, was immediately promoted to the presidency, and W. D. Harris was elected to fill the vacancy.

BUFFALO ELECTRICAL SOCIETY.

On Monday, Dec. 19, Mr. Frank Kitton read a paper before this society on "Magnetism," which was listened to by a largely attended meeting. The lecturer illustrated his remarks by numerous experiments. After the discussion which followed, seven new members were elected. The librarian reported the addition to the library of ten new books.

ELECTRICAL SECTION BROOKLYN INSTITUTE.

On January 13, Mr. Albon Man is to lecture before the section on the interesting subject: "What is Electricity: Is it Force or Only Matter?" This should provoke a lively discussion. On January 20, Mr. E. H. Lyon will lecture on "The Long Distance Telephone," with the help of lantern photographs and a collection of apparatus. During the evening a band playing in Chicago will be heard in the hall, by means of the telephone.

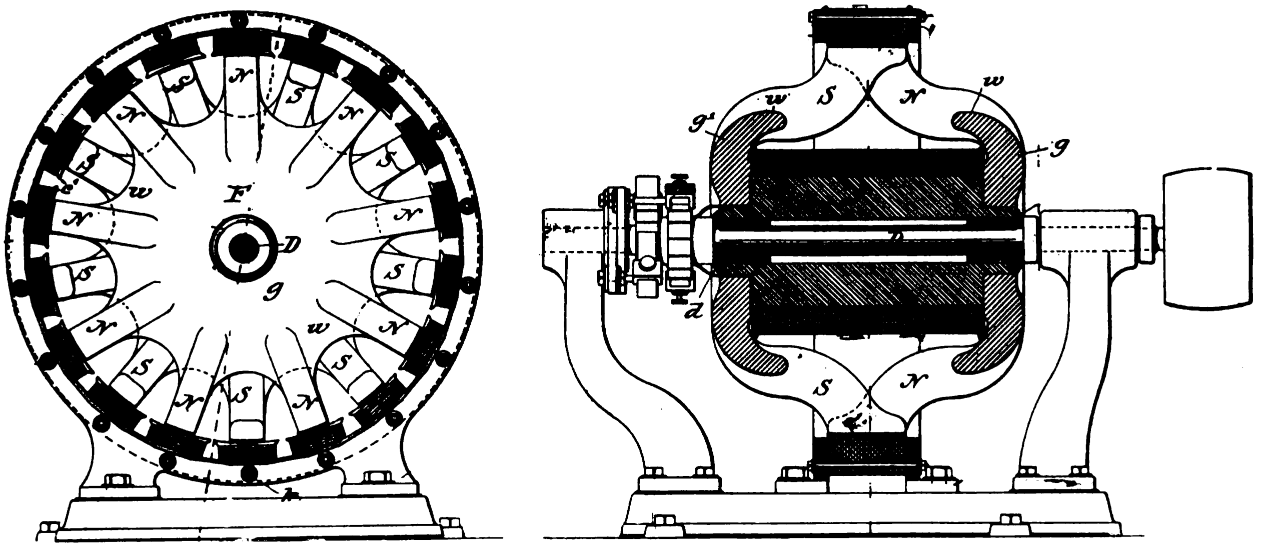
CHICAGO ELECTRIC CLUB.

Resolutions of regret and condolence have been adopted by the Chicago Electric Club, touching the recent death of two of its members—George H. Meeker and M. M. M. Slattery.

PATENT NOTES.

WOOD'S ALTERNATING CURRENT DYNAMO.

With the object of avoiding losses due to the leakage of magnetic lines across the poles of the field magnets and from arm to arm through the armature core in alternate current machines, Mr. James J. Wood, of Fort Wayne, Ind., has recently designed a machine which is described in a patent just issued to him. The machine, which is shown in two views in the accompanying engravings, has polar arms which instead of being laid backwards close against the exterior of the exciting coil, are turned outwardly away therefrom at the middle, and terminate in outwardly radiating polar ends. The armature core is reduced from the entire width of the field magnet to a width of approximately only one-quarter, and the polar ends or faces of the arms N S are made of the same restricted width as the armature core. In this manner the lines of force are confined and concentrated, being forced to pass from the arms N N to the arms S S by entering the armature core, and consequently passing through and cutting the armature coils, so that very nearly all of the lines of force are made effective in the generation of electric potential.



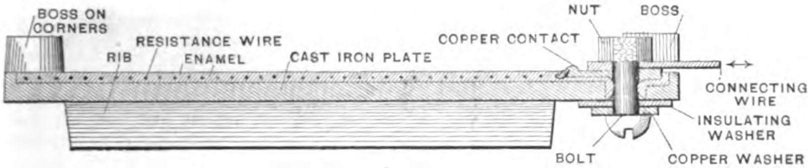
Figs. 1 and 2.—The Wood Alternating Current Dynamo.

The field magnet is further strengthened by constructing it with the discs g g', which are turned inwardly or toward the medial plane of the field magnet, so that these discs are cupped, as shown in Fig. 2, so that they partly inclose the end portions of the exciting coil or coils. The cupping of the discs is effected by the formation of webs w w between the successive arms N N on one disc and S S on the other, these webs being turned inwardly following the direction of the arms, and thereby constituting the cupped portions of the discs, and being also formed with their outlines joining the arms by easy curves so as to distribute the lines of magnetic force to the arms. The inductive effect of the coil sets up lines of magnetic force extending longitudinally through the core f, and radially through the discs g g', and by the cupping of these discs to partly embrace the ends of the coils, the exterior portion of the coil is made effective to add to the magnetization of the polar arms by setting up lines of magnetic force in the cupped portions of the discs, which lines are distributed to the respective arms. The field magnet is thus made stronger than it would be without the discs, and without the cupping of the discs.

THE CARPENTER ENAMEL RHEOSTATS.

The unique properties possessed by the enamel rheostats made by the Carpenter Enamel Rheostat Company, of Bridgeport, Conn., have from the very beginning claimed the attention of electrical engineers, with the result that the various demands made upon the company have led it to undertake the systematic manufacture of a large range and variety of rheostats for all kinds of electrical circuits and work.

The principle of the Carpenter rheostat is the conduction and dissipation of heat by holding a resistance wire in intimate mechanical contact with a supporting plate so that the heat generated in the resistance wire, by the passage of a current, is rapidly conducted to the plate, which becomes the radiating surface. This is accomplished by the use of enamel, which attaches the wire to, but insulates it from, the radiating surface plate, and which also completely surrounds the wire and protects it from chemical action. In this way the capacity of a resistance wire for current is greatly increased. In practice it is found that a wire that will carry a certain current when exposed to the air, will carry ten times that amount of current safely in this rheostat. On this principle, since the cross section of the conductor can be greatly reduced, it follows that its length can be also proportionately shortened for any required resistance, and no consideration of mechanical strength of the wire enters into this construction since it is so perfectly protected and supported on all sides. For example: A No. 20 B & S German silver wire will, in this rheostat, will carry 25 amperes and 80 feet of the wire coiled upon the surface of a plate 10 x 10 inches, will absorb and dissipate five kilowatts of energy in starting a five kilowatt motor of 220 volts under full load.



SECTION OF STANDARD RHEOSTAT PLATE

FIG. 1

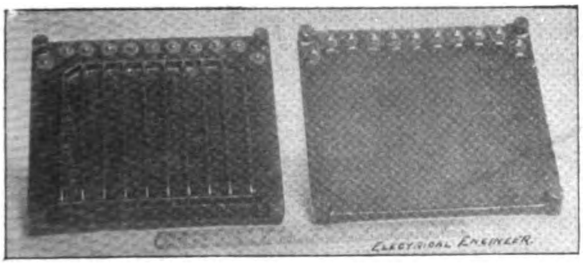


FIG. 2.

To increase the radiating surface, the back of the disc is provided with ribs for extending its radiating surface. The plates will dissipate continuously eight watts per square inch of one surface, *i. e.*, a 10 x 10-inch plate or 100 square inches, will dissipate 800 watts. The temperature of the plate dissipating energy at this rate is entirely safe, as it will not char wood or similar materials when operating under this condition.

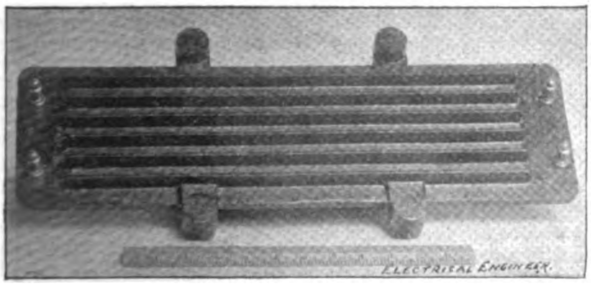

FIG. 3.

These plates will carry for a few seconds when used as a motor starting rheostat, and for similar purposes, a current two and a half times as large as that for which they are rated for continuous service; that is, they will safely dissipate for, say, 15 seconds, six and a quarter times as many watts as they are rated for in continuous duty.

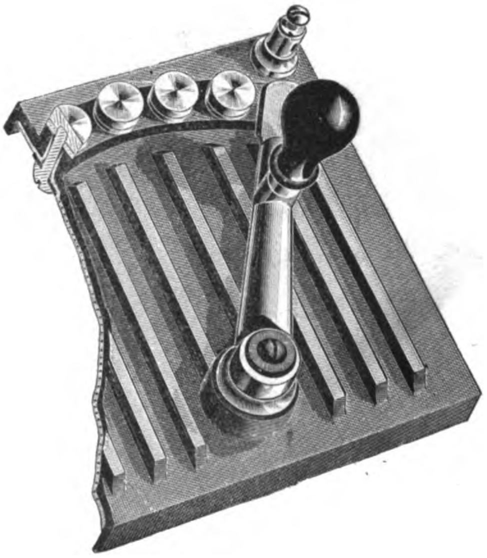

FIG. 4.

For convenience in rapidly supplying the demands of concerns preferring to furnish their own regulating switches, "Standard Plates" for four sizes of motor starting rheostats are always carried in stock. These plates have bosses or lugs at the corners for convenience in attaching to a switch, and are provided with connecting bolts, insulators, etc., at the connecting points of the resistance, as shown in Figs. 1 and 2. The resistance of these standard plates is such that sufficient current will pass when the armature is at rest to give slightly more than the full torque of the armature at full load. They will carry for 15 seconds the full rated current of motor, *i. e.*, a 5-kilowatt, 220-volt motor plate will stand 20 amperes on all steps for 15 seconds. Plates subjected to a certain current continuously must be of such size as to stand for 15 seconds a current two and a half times as much. That is, for continuous service the plates are guaranteed for only 40 per cent. of their rating for 15 seconds. The one and two kilowatt sizes have equal steps and same size wire throughout, except the last two steps next to short circuit, but the three and five kilowatt sizes have graduated or tapered steps, several different sizes of wire being used in their construction, so the last few steps will stand more current for a longer time. These standard plates are built for 220 and 500 volts, but are made also for 110 volts.

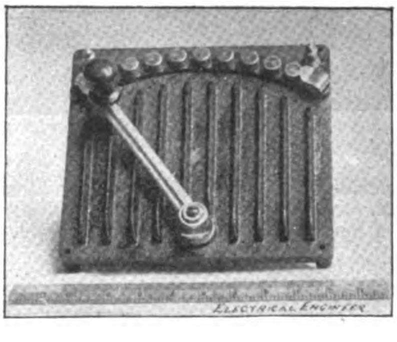

FIG. 5.

The plates are provided at each contact with small brass bolts, nuts and copper washers ready for receiving the wires. In addition to motor starting plates, several other plates are made with resistance to order where the resistance does not exceed 50 ohms, and not less than three ohms. Plates for low resistance and high ampere capacity are made with four wires in multiple in one section, and two sections on one plate separate from each other. This plate is shown in Fig. 3. These sections may be connected in multiple or series as desired.

Fig. 4 shows the principle of the Standard Carpenter Rheostat.

It will be noticed that the same iron plate which carries the switch contacts and lever has the coating of enamel on its under side, with the wires embedded in the enamel, so that the rheostat occupies an extremely small space; no more than the switch parts alone of other rheostats, without the coils. The fire-proof and water-proof qualities will be evident from the illustration. Also its compactness, mechanical strength and simplicity.

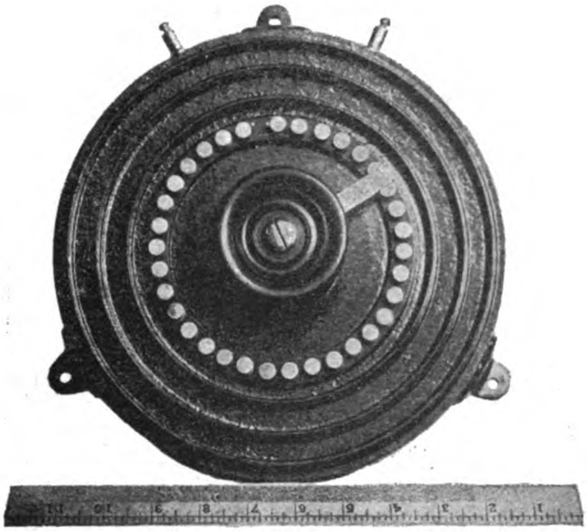

FIG. 6.

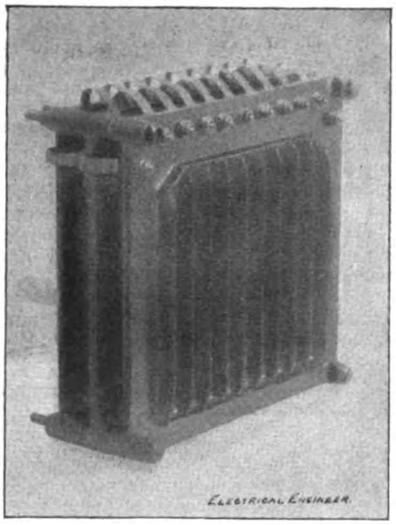

FIG. 7.

Four sizes of motor starters, as shown in Fig. 5, are built. They have the same resistance and current capacity as standard plates for the same size motor.

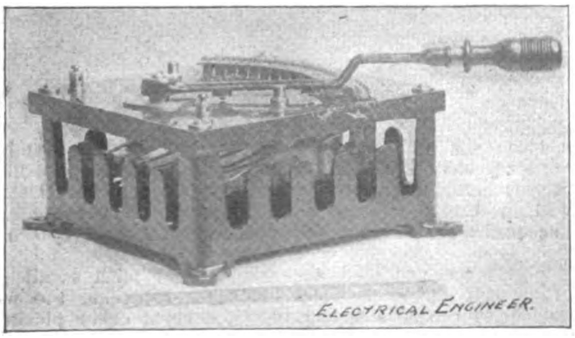

FIG. 9.

Field rheostats are made disc shaped with contacts arranged in a complete circle, as shown by Fig. 6. They are made in four sizes, depending upon the size of machine with which they are intended to be used.

To make a single plate large enough for use in starting a motor larger than 5 kilowatts would make it necessary to have a surface so large as to be objectionable. To avoid this difficulty a number of plates are used either connected in parallel or series, and separated by sufficient space to admit of proper ventilation, connection to the switch being made the same as in the case of standard plates. Fig. 7 shows a 15 kilowatt starting rheostat without switch, made up of three 5 K. W. Standard plates and having their steps connected in multiple. For sizes larger than 15 kilowatt another arrangement has been adopted which consists in using several plates bolted together, mounted in a frame and connected in series, as shown in Fig. 8. Each plate has eight wires arranged into sets, having four wires each. In this way the eight wires may be connected in parallel, or the two sets in series, each set having four wires, in parallel. Thus either 10 or 20 steps may be had with 10 plates, the resistance varying in the ratio of 1 to 4.

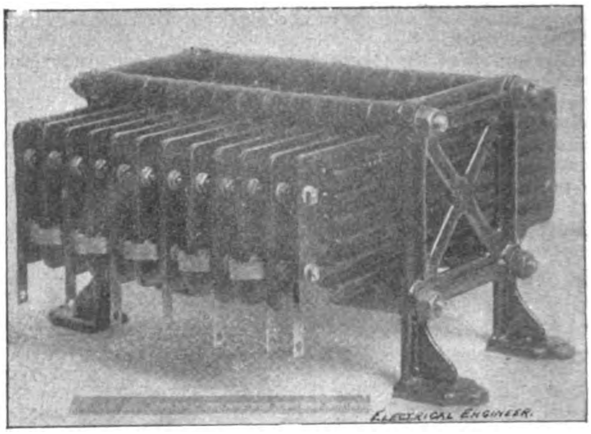

FIG. 8.

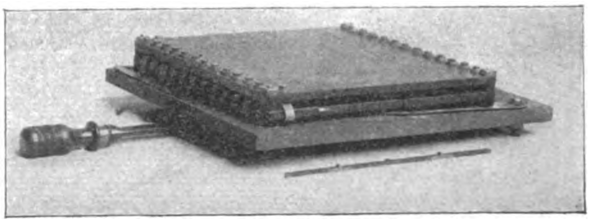

FIG. 10.

Large motor starters are composed of several plates arranged in the same manner as shown in Figs. 7 and 8, but are provided with knife-blade switches similar to that shown in Fig. 9.

Theatre dimmers are made up of plates, the size of which varies with the capacity desired. Several plates are used with their corresponding steps connected in multiple. The plates are bolted to the back of a rheostat switch of the knife-blade pattern, as shown in Fig. 10. The plates with switch are mounted in a ventilated iron box, or provided with angle irons as may be desired. The plates are made with graduated or tapered steps so that the lights will dim gradually, and the total resistance is such that current through lamps is reduced to one-fourth that of full candle power when all resistance is in. The total resistance in the rheostat to accomplish this should be about five times the resistance of the lamps when at full candle power.

Feeder equalizers are made in the same manner as large motor starting rheostats and theatre dimmers.

Arc lamp resistances are made in four sizes, and rated for continuous duty, the prices depending upon the size and capacity of the plate. They are mounted on a pedestal as shown in Fig. 11.

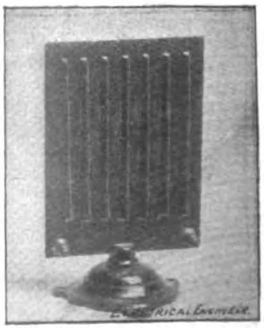

FIG. 11.

Besides its absolutely fire-proof qualities, the Carpenter enamel rheostat possesses the advantage that the resistance wires cannot deteriorate from oxidization, electrolysis, etc. Again, it is compact, requiring less than five per cent. of the cubic space required by the ordinary coiled wire rheostat of the same capacity.

This form of rheostat is cheap, for a certain resistance and carrying capacity can be obtained by the use of a wire whose cross-section and length will both be but one-tenth of that required for a wire used in the air. That is, the total weight of wire, and hence the cost of the same, will be but one per cent. of that usually required.

Finally the rheostat, is unaffected by heat, cold, acids, alkalies, oils and other chemicals, and for this reason is especially adapted for use n mines, breweries, marine vessels, etc., where chemical action rapidly destroys ordinary insulations.

It may be added that Mr. C. D. Shain, of 136 Liberty street, is the selling agent for these rheostats. He will doubtless be glad to furnish further information in regard to the product of the company.

GILBERT'S "DE MAGNETE."

In a letter addressed to the London *Electrician* Prof. Sylvanus P. Thompson doubts the possibility of Mr. P. F. Mottelay having any connection with the forthcoming translation of Gilbert's "De Magnete," to be issued from the press of Messrs. John Wiley & Sons, of this city, and characterizes this publication as an underhand attempt on the part of that firm to forestall the promised translation under the auspices of the Gilbert Club, formed for that purpose some years ago. The reputation for honesty and fair dealing enjoyed by Messrs. Wiley & Sons is such as to render harmless any aspersions such as those cast by Prof. Thompson, who, we are certain, would not have allowed himself to be carried away as he has been, had he been in possession of the facts in the case.

But it seems opportune, nevertheless, to record the fact that long before Mr. Mottelay had begun the actual work of translation, and before the question of a publisher had been considered at all, he laid before us his plan and solicited, and obtained, such aid as we were able to afford him in the prosecution of his work. We also happen to know that not until it was entirely completed was the translation submitted to Messrs. Wiley & Son, so that the charge of a deliberate attempt on the part of that firm to forestall the work of the Gilbert Club is absolutely groundless. We think that the greatest praise is due this American publishing house for its public spirit in bringing out the translation, and we trust the demand will in some measure reward them. Mr. Mottelay's annotated version is intensely interesting, and the advance proof-sheets which we have seen during the past week give promise of a beautiful and valuable volume.

McKINLEY PROTECTION FOR MOTOR-MEN.

Governor McKinley in his annual message to the Ohio State Legislature recommends among other things that the legislature pass an act requiring all street cars to be vestibuled for the protection of motor-men, drivers, etc. He also suggests the street railway companies be required to report all accidents to the railroad commissioners, just as steam railroads have to do.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 27, 1892.

Accumulators:—

Secondary Battery, N. Wladimiroff, St. Petersburg, Russia, 488,726. Filed July 7, 1892.

Claim 1 follows:

In a secondary battery, electrodes whose opposite faces are of like chemical character or nature but unlike polarity and provided with a spiral-face groove

Alarms and Signals:—

Electric Annunciator, J. H. Bates, Hoboken, N. J., 488,536. Filed June 27, 1892.

Claim 1 follows:

In an electric annunciator, the combination with a frame or base, of an electromagnet, an indicator normally out of view, and an armature for the magnet, independent of the indicator, but jointed to the indicator substantially as shown and described whereby the armature is adapted to positively actuate the indicator.

Electrically Repeating Signal, S. D. Field, Yonkers, N. Y., 488,550. Filed Mar. 5, 1892.

The essential feature consists in originating vibration at a central point and establishing communication between several distant points by damping at one distant point the vibrations developed at the central point, thus causing an intensified reproduction of the vibration at another distant point.

Electric Annunciator, A. B. Lyman, Cleveland, Ohio, 488,567. Filed Oct. 26, 1891.

Employs a pair of magnets and push-buttons connected in multiple arc with a vibrating armature common to both magnets and forming a part of each circuit, and an additional battery and push-button connected directly with one of the magnets.

District Signal Box, C. E. Scribner, Chicago, Ill., 488,579. Filed July 3, 1888.

Provides an answer-back attachment upon district signal boxes operated by a moderate increase of battery current.

Thermostatic Indicator and Adjuster, E. C. C. Krogh, Monmouth, Ill., 488,611. Filed Sept. 2, 1892.

Electric Railway Signal, F. P. Schlosser, Birmingham, Ala., 488,615. Filed June 31, 1892.

A device by means of which the engineman of one train is notified, by means of electrical devices located upon his train, of the approach of a second train.

Push-Button and Thermostat. E. L. Ashley and W. H. Camp, Waterbury, Conn., 488,645. Filed May 25, 1892.

A push-button having a metal shell and a fusible insulation by means of which a supplementary contact is normally held away from said shell.

Watchman's Time Recorder, W. L. Bundy, Binghampton, N. Y., 488,687. Filed Oct. 19, 1891.

Distribution:—

System of Electric Distribution, C. J. Van Depoele, Lynn, Mass., 488,928. Filed June 27, 1889.

Relates to a system of distributing electric currents by means of which a plurality of circuits can be supplied with current of the desired potential from a generator giving currents of a potential above that which is required.

Lamps and Appurtenances:—

Electric Arc Lamp, E. Thomson, New Britain, Conn., 488,585. Filed July 2 1888.

Has for its object to secure by mechanical means, without the use of clock work or retarding mechanism, a self-regulating feed for the carbon rod.

Incandescent Electric Lamp, F. H. Prentiss, New York, 488,635. Filed April 4, 1892.

Employs a section of easily fusible glass below the metal cap for the purpose of facilitating the repairing of broken filaments

Incandescent Lamp, F. H. Prentiss, New York, 488,636. Filed April 27. 1892.

Employs a cap composed of two parts, one permanently fastened to the glass bulb and easily attachable to the other.

Duplex Arc Lamp, H. M. Odell, Detroit, Mich., 488,696. Filed March 28, 1892.

Relates to special mechanism for transferring the current from the first to the second set of carbons, and from both when the second is consumed.

Regulating Socket for Incandescent Electric Lamps, E. E. Ries, Baltimore, Md., 488,835. Filed July 6, 1891.

A self-inductive socket for alternating current lamps.

Device for Raising or Lowering Electric Lamps, W. Doran, Skowhegan, Me., 488,878. Filed Dec. 4, 1890.

Coupling for Light Fixtures, J. A. O'Neill, Boston, Mass., 488,916. Filed July 28, 1892.

Regulating Socket for Incandescent Electric Lamps, E. E. Ries, Baltimore Md., 488,951. Filed July 6, 1881.

Claim 1 follows:

A regulating socket for incandescent electric lamps, etc., provided with a self-inductive conductor within the socket, in the filament circuit, and means for varying the degree of self induction of said conductor.

Metal Working:—

Electrical Soldering Iron. C. L. Coffin, Detroit, Mich., 488,871. Filed July 20, 1891,

Electrically Heated Soldering Tool, C. L. Coffin, Detroit, Mich., 488,872 Filed June 11, 1892.

Miscellaneous:—

Electrolytic Apparatus, T. Craney, Bay City, Mich., 488,708. Filed Apr 1892

Electric Cigar Lighter, E T. Gutberlet and W. R. Izard, St. Louis, Mo. 488,889. Filed June 27, 1892.

Railways and Appliances:—

Trolley Catcher, W. L. Browne, Worcester, Mass., 488,706. Filed July 8, 1892.

Provides means of automatically notifying the motor-man when the trolley leaves the wire.

Closed Conduit for Electric Railways, F. Mansfield, New York, 488,738. Filed Oct. 1, 1891.

Employs a swinging hood provided with interior brackets and an insulated arm secured to the brackets with one end projecting therefrom and provided with a contact plate.

Trolley Wheel, L. J. Hirt, Arlington, Mass., 488,811. Filed July 28, 1892.

A wheel having the walls of the groove made thin near the bottom and reinforced by ribs, so that side wear will become visible from without while the wheel is still effective.

Electric Railway Trolley, C. J. Van Depoele, Lynn, Mass., 488,929. Filed Jan. 31, 1890.

Claim 1 follows:

In an electric railway, the combination with a suspended conductor having a grounded return, of a vehicle having a contact carrying rod or arm extending to the underside of the suspended conductor, and an insulated operating device for the said contact rod or arm.

Electric Locomotive, C. J. Van Depoele, Lynn, Mass., 488,930. Filed Apr. 1 1891.

Claim 1 follows:

An electric locomotive having a driving axle or axles, driving wheels, the hubs of which are rigidly attached to said axle or axles, and radial springs fixedly connected to said hubs and loosely engaging slots in the peripheries of the said driving wheels.

Switches and Cut-Outs:—

Railroad Switch Signal, F. Harris, Guildhall, Vermont, 488,654. Filed Aug. 26, 1892.

An electric device for steam railways by means of which an alarm will be sounded when the switch is open.

Electrical Switch, C. H. Pattison, Boston, Mass., 488 740. Filed Aug. 8, 1892

An electric switch having a universal joint at its fixed point and a number of sets of contacts arranged radially about that point.

Non-Sparking Electric Switch, G. E. Painter, Baltimore, Md., 488,899. Filed Mar. 11, 1892.

Telegraph:—

Electrical Circuit for Telegraph Apparatus, F. W. Jones, New York, 488,940. Filed Aug. 12, 1892.

Contemplates an arrangement of the main and local circuits such that one may repeat in the other, and that the resistance of the circuits will remain substantially uniform.

Telephones and Apparatus:—

Electric Telephonic Switch and System, T. B. Sloper, Devizes, England 488,666. Filed May 18, 1892

An intercommunication system of telephonic switches by means of which any two lines including any number of instruments may be connected directly without an intermediate station.

FREE ADMISSION FOR ELECTRIC SUPPLIES IN THE WEST INDIES.

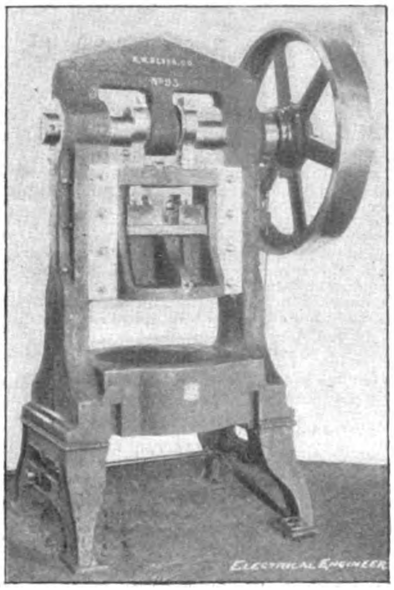
The islands of Trinidad and Tobago will admit free of duty for five years, from January 1, 1893, steam engines, gas engines, boilers, pipes, dynamos, lamps, wires, etc.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE BLISS NO. 95 ARMATURE-CUTTING PRESS.

THE cut shown herewith illustrates a press for blanking out large armature discs as recently built by the E. W. Bliss Co., Limited, 143 Plymouth street, Brooklyn, for the Edison General Electric Company, the Thomson-Houston Electric Company, the Curtis Electric Company and a number of other concerns.



THE BLISS NO. 95 ARMATURE-CUTTING PRESS.

The construction of this press embodies a number of special features which have not heretofore been used in connection with presses of this class.

In order to give a firm support and accurate guidance to the large and delicate dies, the ordinary centre gib has been abandoned and the ways of the slide have been spread apart so as to be as wide as the frame itself. These ways have also been considerably lengthened, adding much to the solidity and accuracy of the machine.

For adjusting the slide, the Stiles eccentric adjustment is used, which enables the operator to quickly raise and lower the slide to the exact point desired without any danger of getting it out of alignment. The pressure with this adjustment is always on solid metal instead of screw threads.

As regularly made, this machine has 32 inches between uprights, and the bed is furnished with a 24 inch round opening, but it is sometimes also made with 40 inches between the uprights and with a 30-inch hole. The weight is approximately 9,400 pounds.

HARRISBURG IDE AND IDEAL ENGINES.

MESSRS. W. R. FLEMING & CO., whose offices are in the *Mail and Express* building, New York City, and who are contractors for steam power plants for electric light and railway service, representing also the Harrisburg "Ide" and "Ideal" engines, have contracted for over 2,500 h. p. of engines during the past 30 days among which are the following plants:—A 1,000 h. p. plant for electric railway service at New Britain, Conn., for which they are building two 500 h. p. tandem compound special railway engines of the "Ideal" self-oiling type; two simple Ideal engines for electric railway service for the Second Avenue Surface Railroad in New York City. These engines are arranged for direct connected multipolar dynamos similar to the four-unit plant now being installed in the new *Mail & Express* Building.

They are now getting ready for export two tandem compound "Ideals" of 225 h. p. each to be shipped to Porto Rico, West Indies. The new Y. M. C. A. Building at Hartford, Conn., are putting in simple engines of the same type for use in lighting their building in connection with the apparatus of the Edison Company.

The Hotel Beresford is being equipped with the same engines, and one has just been shipped to Rochester for the Rochester Car Wheel Works.

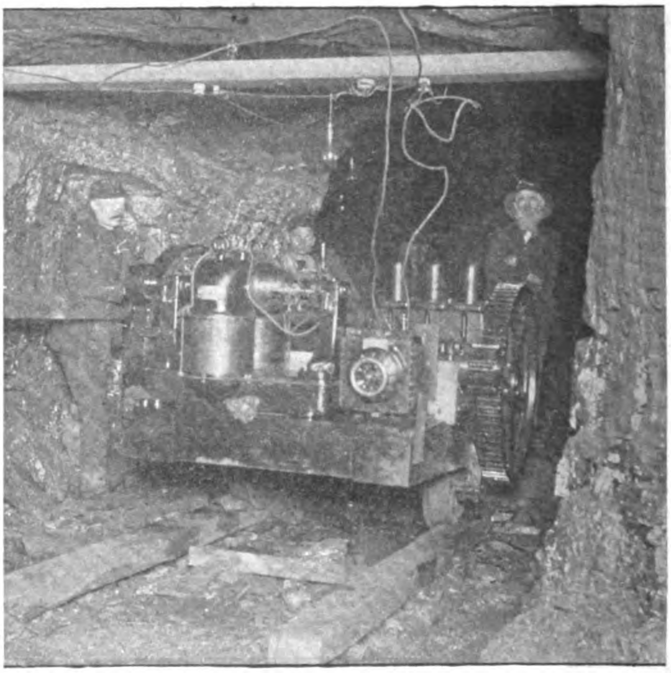
Two standard "Ideal" engines of 175 h. p. each have just been ordered by the United States Government for service in dredging work at Portland, Ore.

ELECTRIC MINE PUMPING AT DURYEA, PA.

AN excellent example of the manner in which electricity is displacing steam in the mining industry is given by the recent installation in the William H. colliery of the Connell Coal Company, located in Duryea, Pa. This colliery is considered one of the most important mines in its district, the average daily output being about 1,200 tons. Many improvements have been made in the plant which will enable the mine to turn out from 1,400 to 1,500 tons per day.

The feature of greatest interest in the improved plant is the electric pump. This is the first electric pump introduced in the mines of that section, and its successful operation is being watched with great interest by all interested in mining matters. The pump is of the horizontal, triplex or three plunger style with 6½ inch plungers and 8 inch stroke. It makes 42 revolutions per minute, and, in its present location, throws a steady, solid stream of water through a four inch pipe a distance of 500 feet from the lower workings to the main pump. The capacity of the pump is 500 gallons per minute. Its entire weight, inclusive of the operating motor, is 6,600 pounds. The electric motor is a 7½ h. p. General Electric Company motor, and the generator, constructed by the same company, and located in the main engine house on the surface, is of 10 h. p. The power is transmitted to the motor over copper wires running down through the air shaft and along the roof of the mine for a distance of 1,700 feet. The pump and motor are mounted upon a wheeled truck and can thus readily be transported to any point in the workings. This quality alone is a strong recommendation to mine managers. The claim that the electric pump needed considerably less attention than the steam pump has been heartily admitted by the managers of the colliery.

By the use of the electric pump a great danger in this mine has been obviated. The steam from the steam pump formerly used, penetrated the roof of the mine in the vicinity, loosening the rock, and rendering the possibility of its fall always imminent. Besides furnishing power for the pump, the electric generator on the surface supplies current to the incandescent lamps, which light the engine houses, the head of the shaft, the inside pump-house, and the workings about the foot of the main shaft. The contrast between the incandescent lamps attached to the roof along the main gangway and the illumination sparsely distributed from the ordinary miner's lamp, is most striking.



ELECTRIC MINE PUMPING AT DURYEA, PA.

If after a few months trial, the new system of lighting and pumping is pronounced successful, the colliery company intend still further to utilize electricity in their mine, and put it to other uses, such as to operate drills and locomotives.

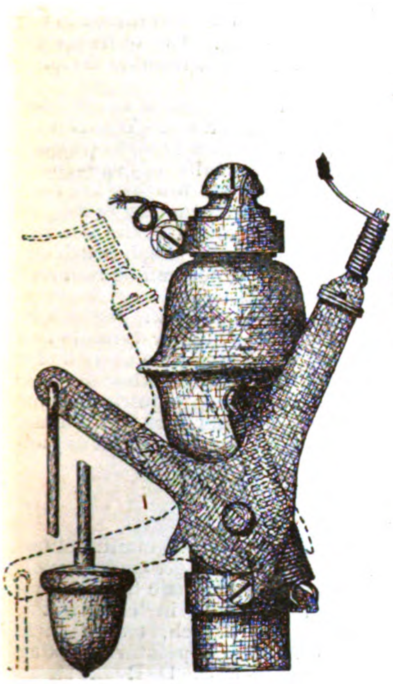
THE "PARKE PENDANT" GAS-LIGHTING BURNER.

THE "Parke Pendant," is a new electric gas-lighting burner, possessing several novel features and points of superiority. In this burner, which is shown in the accompanying engraving, there is no ratchet or complicated springs to get out of order. It is simple in construction, reliable in operation and absolutely safe in use.

To turn on and ignite the gas, the pendant is pulled. This movement brings the arm into the position shown by the dotted lines, and causes the spring (which is back of the arm, having been shown through in the drawing, to more readily explain its operation), which has passed its centre, or point of greatest tension, to hold it securely in that position, until released. To turn off the gas and extinguish the light, the pendant is slightly raised, upon which the spring will carry the arm, and also the gas valve (to which it is firmly attached) back to its original position.

As the position of the arm, which determines the position of the valve, can always be ascertained by taking hold of the pendant, all danger of allowing the gas to remain turned on, when from any cause the spark fails to ignite it, is avoided.

These burners cannot short-circuit. They are made in the best manner. Valves are all hand-ground, and thoroughly gas-tight. A pendant of suitable length, with solid brass acorn, is furnished with each burner. These burners are manufactured by Jno. J. Parke & Co., of No. 821 Cherry street, Philadelphia, Pa.



"PARKE PENDANT" GAS-LIGHTING BURNER.

THE NEW WESTINGHOUSE LAMP.

THE announcement now made by the Westinghouse Company in relation to their new lamps is of more than ordinary interest at this time as it foreshadows a departure not only in incandescent lamp construction, but a decided decrease in the cost of lamps to central stations and private consumers. We note the use in the lamps of an attenuated nitrogen atmosphere which replaces the residuary gas of the ordinary air heretofore employed. The Westinghouse Company claim that by this means the filaments are better preserved than where the oxygen atmosphere is allowed to be present before exhaustion begins.

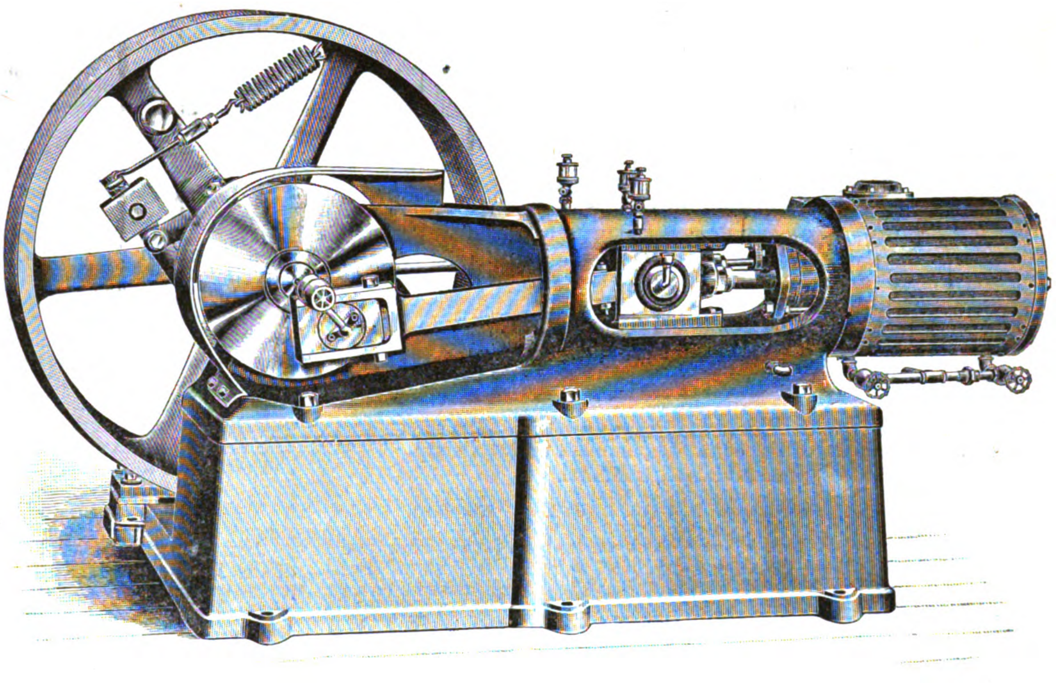
The lamp being made in separable parts the company also contemplates the renewal, on a large scale, of burnt out filaments. For this purpose it proposes to establish "renewal stations" in all the large business centres and thus to afford convenient and expeditious means of providing their customers with lamps having new filaments. With the discounts to be allowed, the cost of lamps to central stations for 8, 10 and 16 c. p. lamps will be 30 cents, subject to a discount of 10 per cent. and to others of 2½ per cent. upwards. In addition to this an allowance of 10 cents will be made for every lamp returned unbroken to the factory, thus making the cost of renewals 17 cents to central stations. For 20 and 25 c. p. lamps the prices will be 35 cents each, subject to the same discounts and allowances.

THE RACINE HARDWARE MANUFACTURING CO.'S ENGINE.

WE illustrate on this page the new horizontal engine, built by the Racine Hardware Mfg. Co., of Racine, Wis., who have until recently confined themselves to the producing of vertical, stationary and marine engines of a high grade. The company are hearty believers in the vertical type wherever they can be used, and especially in their own engines. This company probably carry the largest stock of engines of any builders in the country, with a view to the *immediate filling of orders.* At this writing they have by actual count 174 steam engines complete on the floor or in process. As they make 30 different numbers, they find such stock carrying necessary.

In these days of locating power in basements, there are places where the height of a vertical engine is objectionable. This has induced the Racine Company to commence building a line of horizontal engines from 35 to 100 h. p. in which they embody all that their long experience has proved to be the best. They are what may be called *reasonably* high speed, which means economy.

The engines are built to stand all the stress that their highest ratings demand, with broad margins for safety. It has come to be understood in engine construction that *quality* and not *quantity* of material should govern, which means the best material in the right place. The day has passed for estimating the value of an engine by the amount of pig iron put into it. It will be noticed in deciding what to embody in this their latest, that they have followed what is rapidly coming to be the conviction of practical mechanics and users of power (and at a considerable increase of cost) in supplying an outer support for their power wheels. Years ago this concern commenced building their engines without outbearings, but after costly experimenting and years of experience, they have decided that an out-bearing is necessary to the long life of an engine, thus securing what cannot be secured otherwise, the least wear, and uniform wear, the least time lost in repairs and the least cost of repairs.



RACINE HARDWARE MANUFACTURING CO.'S ENGINE.

IS GRAVITATION INVISIBLE BELTING?

THE SHULTZ BELTING CO., of St. Louis, Mo., had an exhibit and manufactured belting at the St. Louis Exposition, and the following incident is the result of a visit to that institution by one of the pupils of the Divoll School in that city :—

A few days ago a teacher in the Divoll Kindergarten was giving her pupils a little instruction in astronomy and the movements of the planets in the solar system, and said to a little boy: "Johnnie, what causes the earth and moon to spin on their axes like a top as they do?" "That there strap," answered Johnnie. "What strap? What do you mean?" inquired the mystified teacher. "Why," said Johnnie, "I seen on one of them picture cards down at the exposition of that company what had that machine what chops pieces of leather up into little squares, a picture of a strap running around the earth and moon, making them spin around like a top."

WESTERN NOTES.

New Offices. For some time past The Electrical Engineer has found its Western office quarters too small, and it therefore has much pleasure in announcing that while remaining in the same building—the Rookery—it has secured much better accommodation there. Mr. Leslie W. Collins, the Western Editor and Manager, will now be found in Room 575, a large office overlooking La Salle street, one of the busiest thoroughfares in Chicago. He will be glad to see there all the friends of The Electrical Engineer.

The Electric Appliance Company are opening the season by making a particular push on the New England Double Pole Switches. They have held the agency for this switch for the past year and have placed a large number of them although they have always been high in price. The manufacturers have known that they had a good thing and as they have always had all the orders they could handle have not cared to reduce their price to the basis of other makes. Having increased manufacturing facilities now however, it has been decided to make a cut in price and increase the business, and the Electric Appliance Company are preparing for a largely increased demand.

The Card Electric Motor and Dynamo Co., Cincinnati, O., are pushing work as hard as they can on their fine new factory, but meantime are seriously crowded in their old manufacturing quarters, and have had to remove their offices in order to get more elbow room. They have temporarily established their offices in the Fosdick Building, 59 West Fourth Street, Cincinnati.

Mr. F. W. Best, formerly with F. W. Best & Co., Denver, Col., has been appointed Eastern representative of the new monthly magazine, *World's Fair Electrical Engineering*, with headquarters in the Tribune Building, New York.

The Crane Company, of Chicago Ill., have secured the agency for the Western states for the De Rycke centrifugal steam separator and grease extractor, and are now equipping several electric light central stations with this device.

The Enterprise Electric Co., W. C. McKinlock, president and treasurer, have found new and larger quarters at 307 Dearborn street, Chicago, giving them a store 25 by 125 feet, with basement corresponding.

Dr. J. A. Hornsby has been nominated by Director General Davis as Assistant Chief of the Department of Electricity.

THE NEW MATHER DIRECT COUPLED DYNAMO.

In cities where land is very valuable and buildings rival each other as to which can get nearest the sky, the division of space and its utilization for the steam plant, heating and ventilating apparatus, electric light system, and other apparatus which has to go in the basement and is necessary to make the modern office building or apartment house complete, has become a very serious question with architects, builders and owners of large buildings.

Preparatory to submitting plans for an electric light plant, the writer recently called upon the owner of a large business block in New York. The first question was: "Where do you want to place your engine and dynamo?" This was a puzzler! Every available feet of space was occupied, and the only vacancy that could be found was about six or eight square feet out under the sidewalk. What was to be done? Belting and counter-shafting were an impossibility. Nothing would do but a dynamo that was coupled direct to the engine and built on the same base.

In nearly every large building in our cities, cases similar to the above will present themselves. The Mather Electric Company of Boston, Mass., was among the first to realize the situation, and after many months of experimenting, have developed and perfected a slow speed, multipolar dynamo which can be coupled direct to any first-class high speed engine.

The dynamo itself is one that does not require special or expert care. No electrician is needed especially for it, and any steam engineer after a few instructions can take entire charge of its operation. The Mather dynamo, throughout, is built upon thoroughly scientific principles, and is theoretically perfect in electrical design. Its efficiency is as high as that of any high speed machine, having as large a capacity in lights per horse power and consuming as little fuel as the best direct current incandescent machines.

The electrical design lends itself very readily to superior mechanical construction and full advantage of this fact is taken which gives the smallest number of wearing parts and least liability to get out of order. The result is a system that is absolutely reliable under all circumstances and a machine perfect in all its mechanical details.

The advantage, electrically, of the form of magnet used in the Mather system is so great that carefully conducted tests have shown that its form is the best that could be adopted. There are no joints, breaks or abrupt corners to oppose the passage of, or to direct the lines of force, points which are of great importance in a magnet. A large part of the success of the Mather system is due to this particular form of field magnet.

In place of using cast iron for the field magnets, cast steel is used entirely. The permeability of this material is greater than cast iron in the ratio of about nine to five, which allows of a great saving in space and weight. Being easier to create a greater magnetic strength than in cast iron, it materially reduces the size of the fields and greatly increases the efficiency.

The armature is a modification of the well-known Siemens type, the object being to design an armature that would produce the current without destructive sparking, and at the same time to do away with all unnecessary losses due to Foucault currents, and other sources of loss. The armature is carefully balanced and runs perfectly true and without vibration. When operating under full load there is no undue heating, a very important point.

All armatures are slotted and the wires imbedded. The mechanical advantages of the armature wires being provided with a perfect iron-clad bed are, that the slot thoroughly protects these wires from external injury, and prevents stripping off, due to a possible short circuit in the case of generators, and to sudden starting in that of a motor. The tooth projections decreasing the air gap, the slotted armature provides also a more perfect continuity of the magnetic circuit.

The shaft is of the best quality of steel, ground on dead centres, and is of ample size so that when connected direct to the engine shaft there is no tendency to springing. The bearings are self-oiling, and the plan employed insures the continuous flooding of the entire length with oil.

Sparking at the commutator is the cause of most of the trouble that comes to users of electric lighting apparatus. The Mather machines are so perfectly balanced, both electrically and mechanically, and the brushes and holders so carefully adjusted, that there is practically no sparking, and when the brushes are once properly adjusted the least attention given them the better, as they gradually adjust themselves to the commutator, and will run for a great length of time without being changed. Each brush can be adjusted independently by a simple device, or can be removed from the commutator by a single movement.

In the regulation of the Mather dynamo, automatic regulators, so called, are entirely done away with. The Mather dynamo is a perfectly automatic machine in itself, regulating absolutely under all changes of load without outside regulators, or other devices. It is also automatic in its consumption of power, requiring power only in exact proportion to the amount of actual work being done. The Mather dynamos for direct connection are built in all capacities from 200 to 3,000 16-c. p. lights.

NEW YORK NOTES.

Joseph De Rycke, 145 Broadway, New York, manufacturer of the De Rycke centrifugal steam separator and grease extractor, recently furnished to the Milwaukee central electric lighting station a second order of one 4 inch and one 10 inch separator, and a third order of five 4 inch, four 5 inch, two 6 inch, five 7 inch, four 10 inch and two 12 inch separators, making a total with the previous order, of thirty-six of the De Rycke steam separators and grease extractors in use in this station.

Mr. E. B. McClees, has, we are very glad to note, returned to an old post after two or three years of work in other directions, and may now be found at the Kerite headquarters, Mail & Express Building, this city. Mr. McClees has been so closely identified with Kerite interests that his return under Mr. Brixey's management will be hailed with delight by all old friends of the concern.

Chas. A. Schieren & Co., 45 to 51 Ferry street, have received a contract for all the belting for the new *Herald* Building, to consist of belts from 35 inches down to 12 inches; and also large orders from the Gas and Electric Co., of Wichita, Kan., and the Lima, Ohio, Electric Light and Power Co.

Captain Willard L. Candee, American manager of the Okonite Co., Ltd, sailed December 31st, on the North German Lloyd steamship "Saale" for London on business connected with the company.

Mr. Chas. P. Geddes has been elected secretary and treasurer of the Interior Conduit and Insulation Co., in the place of Mr. F. A. Mason resigned. Mr. Geddes is an old insurance man.

The General Electric Co. has secured an injunction against the Perkins Lamp Co., from the United States Circuit Court, at Hartford, Conn.

THE
Electrical Engineer.

VOL. XV. JANUARY 18, 1893. No. 246.

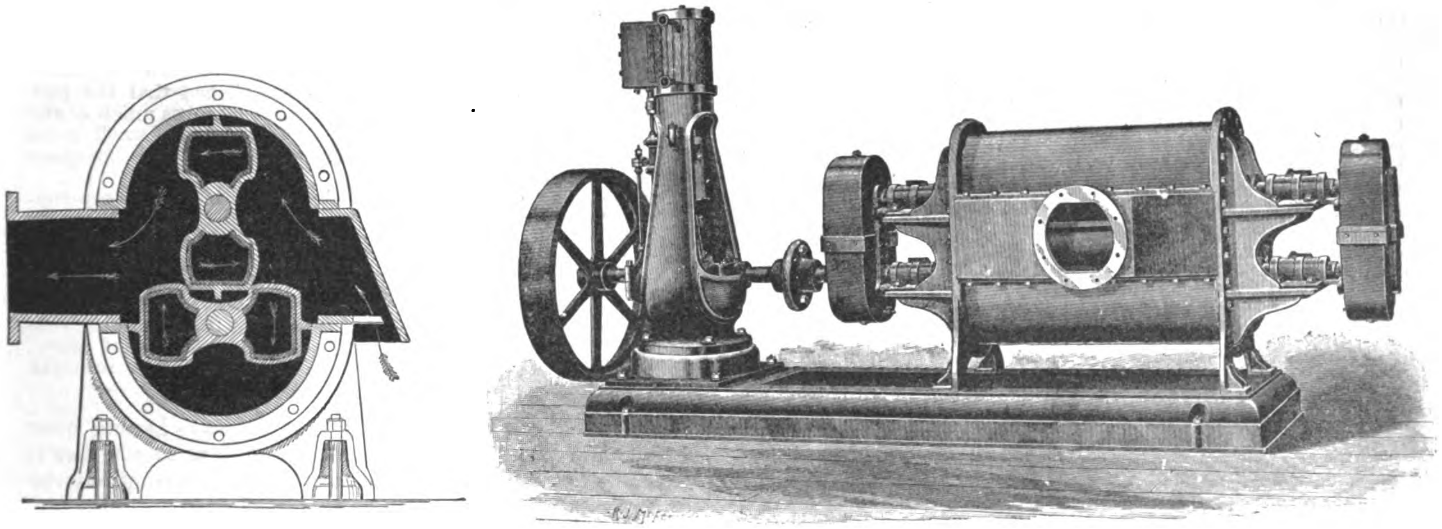
NEW YORK'S ELECTRICAL SUBWAYS.—III.

BY

Wm Maver Jr.

XI.—GAS IN THE SUBWAYS.

It is, I think, within bounds to say that the right to exist of an extensive electrical subway, designed to permit the free drawing in and out of cables from the ducts, in the streets of large cities, will depend upon the employment of a positive means of excluding from the subways the gas which may leak from adjacent gas mains.



FIGS. 19 AND 20.—APPARATUS EMPLOYED FOR BLOWING AIR INTO, AND EXCLUDING GAS FROM, THE NEW YORK SUBWAYS.

In Philadelphia, where, perhaps, the first "drawing in and out" subway system was employed in this country, (1882), the frequency of explosions of gas in the subways necessitated prompt action, and resort was had to blowers to expel the gas.

In New York city also, a number of explosions of more or less violence occurred within a comparatively short time after the construction of the first few miles of electrical subways. From May 9th, 1887, to March 25th, 1889, there were 12 such explosions. It was thus rendered obvious that a preventive of these explosions should be found, and various schemes, short of the expensive one of establishing and maintaining blower stations to exclude the gas from the subways, were devised and tried; with the result that the latter plan was adopted as the only effectual way of dealing with the question—assuming that the escape of gas from the gas mains would be permitted to continue. That this has been the proper method of dealing with the question is attested by the fact that not an explosion has occurred in the New York subways since the "blowers" were installed.

Much of the credit for the successful establishment of the "blower" equipment in this city is due to the study and work of Mr. Wm. J. Baldwin, the well known heating and ventilating engineer, to whom the matter was entrusted by Mr. Leonard F. Beckwith, the chief engineer of the Subway Company of this city. It will be evident from a reading of the numerous and interesting excerpts, which, by the courtesy of these gentlemen, I shall have the pleasure of quoting from Mr. Baldwin's reports on the subject, that he has made it his own.

The subject is one of so much importance to all who may contemplate the construction of electrical subways in other cities, where conditions more or less similar to those that exist in this city are to be encountered, that it, I think, well merits the space that may be given to it here.

There were, of course, various theories offered as to the cause of the explosions that occurred in the New York subways, some attributing them to the spontaneous combination of electrolytic hydrogen with atmospheric air, etc. One theorist asserted that a certain explosion was unquestionably due to the hydrogen set free from waters of condensation by a galvanic action set up between the lead covering of the cables and the iron of the ducts, citing in proof thereof that the workmen saw no flame at the moment of the particular explosion. The flaw in this theory was that the explosion in question had occurred in a creosoted wooden conduit.

To those, however, who were most intimately concerned, the cause of the explosions in the New York subways was not far to seek—namely, a spark, and an accumulation of illuminating gas in an explosive proportion with atmospheric air. The leaky condition of the adjacent gas mains did not leave much doubt as to the source whence the gas came, and the origin of a spark could readily be accounted for, if not directly traceable, as it was in several instances.

The work set Mr. Baldwin was "to examine the subways and manholes with a view to prevent the accumulation in the manholes and conduits, of illuminating and other gases in quantities sufficient to form explosive mixtures with air, or jeopardize the health of workingmen who are obliged to enter them."

"The chief cause of the vitiation of the air of the subways," says Mr. Baldwin in his report, "is the leakage into them of common illuminating gas from the many gas mains which run parallel to, or cross each other below the surface of the ground in the principal streets through which the electrical subways pass. The leakage of gas in the case of cast iron pipes, with hub and spigot joints, calked with lead, even when laid in the best manner, cannot be, or at least never yet has been, altogether prevented, and two per cent of such leakage from the mains may be assumed as occurring in the best practice. In the city of New York, this leakage reaches five or six per cent. In the older streets where several sets of gas pipes run parallel to each other, or nearly so, and when other pipes, as pipes for steam and water, and the sewers, parallel the gas pipes, the leakage is the greater; the joints of the gas pipes being injured by the frequent disturbance of the streets and the settling of the ground, the pipes and fittings also often being defective and the workmanship poor. Under the most favorable circumstances, however, as stated, there will be leakage of gas from the joints of cast iron pipes even with the low pressures carried in the mains, as every hub and spigot, with its lead filling, is an expansion joint, which has to accomodate itself to the expansions and contractions of the pipes. This change of length amounts to from $\frac{1}{40}$ to $\frac{1}{30}$ of an inch for every 12 feet length of cast iron pipe (and possibly more) for the range of temperatures in the ground to which the pipes are exposed at the depth at which they are usually laid—often not more than two feet below the surface. It is thus evident that absolutely tight hub and spigot joints can not be obtained and that the leakage of gas from the mains is not likely to ever be much less than at present, under the methods of laying the mains employed in New York. A more serious cause of gas leakage into the earth of the streets, constituting a large percentage of the whole, is that due to the wrought iron service pipes and their cocks and taps. These pipes corrode rapidly in the ground; many of them are pitted and broken and leak dangerously when the earth is removed from around them. Often the pipe is little more than a film of oxide of iron (rust) in the shape of a tube. Although many of these 'services' have been abandoned, they are not cut off from the main, and trouble from this source is more likely to increase than to diminish, in the future. In England and on the Continent the usual practice is to use lead or block tin service pipes, with brass taps, for gas. This custom adopted here would tend to greatly diminish the leakage which is now so general and troublesome, not only in the electrical subways, but also in the cellars of buildings adjacent to the gas mains.

"The second cause of the vitiation of the air in the subways and manholes is excessive dampness (vapor caused by heat), which in some cases amounts almost to steam; percolation of water from low wet ground or from sewers, and permeation of sewer and other gases through the walls.

"The leakage of the gas from the mains into the earth of the streets, causes pressures slightly above atmosphere. This excess of pressure causes movement of the gas in the direction of least resistance, that is, upward to the surface and into such cavities as exist below the surface. The leakage of gas into the cavity results in the gradual displacement of a part of the air, gas taking its place, until an explosive mixture is formed.

"To prevent the formation of this mixture in the manhole vaults, they must either be aired so thoroughly and continually that the gas will never accumulate in sufficient quantities to form an explosive compound, or measures must be taken to prevent the entry of the gas into the manholes."

As has been already stated in the description of the manholes, they are built in a manner which would seemingly prevent the intrusion of gas, but experience has shown that the constant heavy jarring to which they are subjected, sooner or later produces minute fissures in the walls through which gases percolate into the manholes. Experiments have been made to determine whether painting the walls of the manholes would keep back the gases in the earth, but the result was disappointing. In Mr. Baldwin's opinion the painting or coating of the bricks with any substance is of little or no service except that, in connection with plenum, or pressure, ventilation, a cement might be employed to lessen the outward leakage of air through the vaults at points where such leakage was found to be excessive.

Many experiments were also made with siphonic ventilation. Vent pipes about two inches in diameter were used in some of the manholes. One pipe connecting with the upper part of the manholes entered a lamp post; a similar but shorter pipe, with a bend in it, was carried from a few inches above the curbstone to the bottom of the vault.

"The purpose of this arrangement of pipes was to set up and maintain siphonic action, the long leg of the siphon, or lamp post, exhausting the air from the manhole and producing a slight condition of vacuum therein, while fresh air was drawn into the manhole through the short leg of the siphon. This result was attained to a limited degree. A small piece of paper when held over the inlet, indicated a general inward current through the induction pipe or short leg of the siphon; though this current was at times interrupted and reversed by slight back-draughts. The strong smell of gas at the head of the outlet pipe was also an indication that, at least on a sunny day, this apparatus had some aspirating power. By contrast with the unventilated manhole, this method of ventilation was not without beneficial results, which were evident also in the comparative dryness of the vaults. The ground and brick-work were drier and the gases were not so apparent to the smell. The presence of gas in it, however, was apparent and how long a person could safely work there is uncertain, while the question of the safety of taking a light into the vault could not be determined, as it is a well-established fact that mixtures of air and gas which are explosive can be breathed for some time without injury. And it is also known that when the specific gravity of the gas is greater than that of the air an explosive mixture may lie near the floor, while above it may be one which can be breathed for a considerable time with safety. This condition is always to be feared in unventilated manholes, and even when the manholes are ventilated as just described, there is no assurance that the danger is removed, and the same precaution should be taken as with the unventilated manholes.

"When manholes in damp districts are first opened, the smell of gas seems to be stronger than in the case of manholes in drier ground. This, however, may not indicate more danger from explosion. It may be simply due to the condensation of tarry or volatile substances by the aqueous vapors, which hold the tarry substances in suspension, causing the more pungent smell. These strong smelling vapors may, however, be less dangerous than the inodorous vapors or gases, for it is well established that the passage of illuminating gas through the earth removes much of the odor by which we detect the gas, so that the sense of smell is not to be relied on to decide the question of safety, unless the space has been well aired.

"The use of ventilating manhole covers has also been suggested. These are covers with perforations through them, to permit the excess of air or gases to pass off; but the movement of air through them is very feeble and unreliable and they may be disposed of by saying that ventilated covers of any description give no assurance of positive action, even under the most favorable circumstances. Water will pass through them into the subways, and they would be absolutely useless in times of snow, while in dusty weather they admit all kinds of refuse into the manholes."

These methods of ventilating the subways having been shown to be insufficient, the question arose as to whether it would be better to purify the subways by pressing out the impure air or by drawing it out by suction.

"When air is discharged into an open manhole, at pressures a little above atmosphere, by fans or blowers, in quantities sufficient to produce thorough airing, the pipes which convey the air require to be of comparatively large diameter, as the escape of air from the open, or partly open manholes, or from the vent pipes, will reduce the pressure. In these circumstances, to carry sufficient air a mile or more through the subway ducts would be impracticable and enormously expensive. If, on the other hand, airing is effected by vacuum movements, produced by an exhausting fan, the pipes must be equally large and expensive, and the air drawn to the fan will become so foul that tall chimneys will be needed to effect its discharge without creating a nuisance. It is evident that this method will aggravate the danger of drawing an explosive mixture into the air pipes and fan, and of destroying the plant by explosion. A vacuum or exhaust fan system of any kind also tends to draw the gases out of the ground and into the cavity that is being ventilated or aired. This, in some cases, must be very injurious and defeat the object of ventilation; as when the exhausting operation results in drawing quantities of gas from a large leak near by, into the very manhole it is desired to free from the gas. The lessening of pressure in the manhole increases the influx of gas from the earth and consequently a greater quantity of air must be drawn into the manhole or cavity to keep it at the required standard of purity. On the contrary an excess pressure in the manholes tends to diminish the leaks from adjacent mains, etc."

As already mentioned the foregoing considerations led to the adoption of the pressure system of ventilating the electrical subways of New York City, the plan adopted being to provide by suitable blowers and pipes a pressure in the manholes and ducts greater than the gas pressures in the surrounding earth, and sufficient to renew and change the air in the subways, at least once an hour, the subways being kept as air-tight as possible throughout their length, and the air forced into them being compelled to force its exit through the porous brick walls of the manholes and the surrounding earth, and through the walls of the ducts or accidental leaks in them.

Mr. Baldwin found the cubic contents of the average manhole to be about 250 cubic feet, and estimated the leakage through the walls of the manholes now used, with cover and rubber gasket, at about 500 cubic feet, per hour. The leakage from the wrought iron ducts may be disregarded; that from the cast iron ducts may be placed at about 500 cubic feet per hour, due to defective joints. This, for wrought iron ducts, would require a supply of 500 cubic feet, per hour; and for cast iron ducts a supply of 1,000 cubic feet, per hour, per manhole. There being about 24 manholes per mile of subway, "a mile of subway would require about 12,000 cubic feet of air, per hour, when wrought iron tubes are used and about twice this quantity with cast iron ducts."

In view of the fact that the ducts of the subways could not be utilized for the transmission of this air supply, since they are designed to be filled with cables, special ventilating pipes have been laid parallel to the subways. "A smooth pipe six inches in diameter (shown at the right of the distributing ducts in Fig. 4) is found of sufficient capacity to deliver the required amount of air, 12,000 cubic feet per hour, at a distance of one mile from the blower station with a loss of pressure for friction of about 14 ounces per square inch, so that with 16 ounces of inital pressure a terminal pressure of two ounces is available. A pipe, 8 inches in diameter, will pass 24,000 cubic feet of air through a mile of its length with a loss of pressure of somewhat less than 11 ounces per square inch."

In the laying of these ventilating pipes, they have been extended through each manhole with as little change of grade as possible, and lateral changes of alignment, to avoid obstructing the entrance to the manholes, are made with long easy bends, so as to minimize the loss of pressure due to friction of elbows and change of direction.

XII.—THE BLOWER STATIONS.

The adoption of this low pressure method of ventilating the subways necessitated establishing "blower" stations at different parts of the subways to properly air them. There are now in operation 12 blowers in nine different stations. These stations are enumerated in the subjoined table. The blowers used are manufactured by P. H. & F. M. Roots Co. The blowers are, of course, operated every hour of the 24. They are driven by steam and gas engines, respectively, depending on whether steam can be readily obtained from adjacent boilers. At the station, 145 East Forty-second street, two gas-driven blowers are employed. The gas engines employed are of the Otto manufacture and are, as is well known, self-regulating. An automatic pressure recorder shows, by a card, the pressure maintained by the blowers throughout the day. The steam engines operating blowers are attended to by the engineer in charge of the steam power plant. The gas engines are attended to by an engineer who visits the various stations in rotation. As showing the adaptability of the gas engines to this work it may be stated that the engines in question have been running for three years constantly without repairs and only an occasional shut down for half an hour to allow for cleaning the valves, etc. Figs. 19 and 20 show the blower used and its internal construction.

The following table, kindly furnished by Mr. Baldwin, contains interesting data concerning the blowers, the engines, gas consumption, etc.

Location of Station.	Nature of plant.	Cubic feet per rev.	Pressure of air in oz.	Rev. of engine per minute.	Rev. of blower per minute.	Engine.	Air resistance to blower in h. p.*	Total h. p. not over.	Daily consumption of gas in cubic feet.

* Exclusive of friction of engine, blowers, shafts, belts, etc

TABLE OF SUBWAY BLOWER STATIONS IN NEW YORK CITY.

The blowers in each station are allotted a territory embracing about two miles of subway in two diverging directions from the station and could supply sufficient air for a radius of one and a half to two miles, if necessary.

Where the air pipes leave the blower station and up to a point where the subways diverge, they are of double the capacity of the ordinary air pipes, namely about 12 inches in diameter. Openings which admit of graduation are made in the air pipes where they pass through manhole vaults. These openings range from ⅛ of an inch near the stations to ¾ of an inch at the more remote points. By this arrangement it is clear that air pressure will be maintained in the subways whether or not intermediate manholes be, for any reason, open. The pressure at the ends remote from the blowers is in some cases very slight, but still ample for the purpose.

The question of utilizing high pressure engines and smaller air pipes to operate at greater distances than is feasible with low pressure, thus requiring fewer blower stations, was, as before intimated, fully considered, but the greater economy of operation, etc., of the low pressure led to its adoption.

While it is obvious that but for the presence of illuminating gas in the subways, it would in all likelihood not have been necessary to have incurred the expense of establishing this extensive "blower" system, it may be noted that the forced passage of fresh dry air through the conduits and manhole vaults has had a very marked effect in keeping them dry and wholesome and will from present appearances much enhance the longevity of the entire plant.

There are, it may be said, thus far no marked signs of detorioration of the material of the iron, asphalt, wooden or other conduits of the New York subways. Examinations that have been made of some of the cast iron ducts of the Johnstone conduits, which were laid directly in the earth, show only trifling marks of corrosion.

THE RELATIVE ADVANTAGES OF CONCENTRIC AND DOUBLE CABLES.

BY

Morton. E. Eden

As concentric cables are rapidly coming into use, especially for high pressure alternating currents, it would be interesting to hear from some of your readers their experience as to the durability and advantages discovered.

The relative merits of concentric, as compared with two separate cables, have attracted a great deal of attention abroad, where they advocate their use for high pressure alternating currents. Of course there is a great deal that can be said against their use, but then again there are no doubts as to the advantages attained, for instance as regards the question of induced currents in neighboring wires, for as long as the insulation is good, there is no induction, owing to one conductor being concentric with and enclosed by the other. This is very important when telephone, telegraph and other wires are run parallel with, and in close proximity to, alternating circuits.

Of course, with two separate cables run close together, as for instance in the same conduit, no trouble would be experienced from induction; but, two separate cables do not, as regards their insulation, stand the strain of pulling in so well as a concentric cable, because it matters very little if the insulation on the outside of a concentric cable is slightly damaged.

As to safety to the linemen and public, the concentric cable is undoubtedly better under certain conditions of working, than two separate ones, for if the capacity of the outer conductor with regard to the earth is considerable and the insulation of all parts of the circuit is good, the mean potential of the conductor is the same as that of the earth, and the greatest difference that could exist between the two is that due to fall of pressure, caused by the flow of current in the cable. But if the circuit is faulty, in the converter or at any fitting, the point at which the leak occurs will be of the same potential as the earth and these no doubt will show under given circumstances, a considerable difference of potential.

Mr. Ferranti, I believe, suggested a method of overcoming this difficulty, to ensure that only a small difference of potential can exist, by connecting them electrically at some part of the circuit, and he adopted it in the mains of the London Electric Supply Co., London, England, where with two separate cables laid underground, so that their outer coverings are earthed, the danger of a shock is removed, except when some part of the cable itself is touched. This same danger occurs in circuits where the cables are concentric, unless the concentric principle is carried through to all connections to converters, switches, etc. But the degree of safety obtained by the use of concentric cables over two separate cables is no greater unless the outside covering of the concentric cable is earthed throughout the whole system.

In concentric cable systems as regards testing of insulation, etc., a difficulty is met which is not experienced in a system of two separate cables, for when an insulation test between the two conductors of a concentric cable is required to be made, all connections between dynamos and other apparatus must be disconnected, which is hardly practicable.

As regards the use of lead covered cables for alternating currents, it seems that it would be best to use concentric cables, as with a single conductor cable there must be an appreciable waste of energy from induced currents in the lead covering, this waste does not occur in concentric cables. The higher the frequency, the greater the waste of energy.

Relative to jointing, greater, though not seriously greater, difficulty is met with than with single conductors, more especially with T-joints; but a special junction box will facilitate the making of most joints. It would be most interesting to hear more about the use of concentric cables and their advantages over two separate cables.

One company in London, England, is laying down concentric cables for the alternating system now being installed for the city of London lighting, some circuits having been in use for some months and no trouble whatever being experienced.

INSULATED ELECTRIC CONDUCTORS.—XVI.

BY

James Bowstead Williams M.R.C.

Shellac.—This substance is one of a distinct group which includes copal and amber. It is considered by many to be an animal product, but from an intimate acquaintance with its properties, and after having used it in almost every possible way in which it could be used in the arts, both in its pure state—*i. e., before* it had been "handled" by dealers—and in combinations, the writer believes that it is a vegetable and not an animal product. It is true that it is a very peculiar substance, as regards its combinations, etc., and often behaves in an unaccountable manner when in the hands of a novice; yet, when pure, it is one of the best materials for insulating varnishes, and other compositions, as well, that we possess, and it is well worth the time and study which are necessary to bestow upon it if one is to derive the best results from its use. It is a *very* "select" resin, and does not enter into combinations as readily as most other resins. Being very brittle, the cases are few in which it can be used alone, and, except in special cases, it should be combined with other and tougher substances. When used for varnishes its proper solvent is alcohol. When dissolved in linseed oil it can be thinned with oil of turpentine, if desired. It will dissolve in boiling alkaline solutions in a few minutes. These solutions when used alone or added to glues form useful cements for labels, etc., but not for insulating purposes unless the *dry* layers are *immediately* covered with a suitable waterproofing layer. Shellac will *invariably* crack if applied to fibre or wires which are alternately heated and cooled, unless properly combined. Directions for separating the pure resin from the gum have been given in a former article. This resin forms one of the best lacquers for the exposed brasswork testing and other electrical instruments that can be obtained, for it not only embellishes the work but insulates as well.

Like copal, shellac can be directly combined, when in solution, with other substances provided they are compatibles and are dissolved in the proper solvent. As found in the stores, it is adulterated with rosin. While this may not lower the specific resistance of the material to any great extent, it does diminish its durability, and that in proportion to the amount of rosin present in the mixture. Always reduce the shellac to a coarse powder before using.

Japan driers containing a large proportion of shellac are the best for insulating paints. Formulas for such can be found in the books; but greater care must be taken in making driers for insulating paints than those for ordinary paints.

Shellac is very capricious when used with bituminous matter, especially after standing for a few days.

The writer cannot do better right here than to state a rule which he has followed with the most satisfactory results while making solutions for insulating purposes, namely: Always examine a drop of the *fresh* solution with the microscope, and repeat the examination every two or three days, of the *original* solution. The drop is placed between cover glasses, and examined with low powers. A little practice will enable the operator to distinguish between chemical solutions and mechanical mixtures, and also to detect changes, if any, in originally chemical solutions, but which cannot be detected by ocular examination.

Colophony.—This is a useful ingredient of paints, for it not only unites readily with other substances but also serves as a "binding material" for substances which do not readily combine. It dissolves freely in oils and volatile solvents.

Rosin is best used by first melting it with other material and then dissolving. As a rule the softer kinds are the best because they contain more oil and turpentine than the harder and brittle kinds, which causes them to combine easily with the other material and also to assist in making the paints elastic and tough. High temperature and frequent melting do not injure rosin, as they do shellac, but every time it is heated it becomes more brittle. Rosin oil is a good ingredient for compound solvents.

Bituminous Matter.—This includes those natural and artificial petroleum products which are known as asphaltum, maltha, etc. These differ from each other principally by the proportions of petroleum they contain. As far as *durability* and *flexibility* are concerned—for any asphalt can be made flexible by adding petroleum to it, using heat—there is probably nothing better known, but, unfortunately, the specific resistance of such material is low, as compared with rosin, for example. Were it not for this fact we could not wish for a better paint than maltha dissolved in bisulphide of carbon either with or without the addition of resin, paraffine, etc., to it.

Regarding the effect of asphalt upon highly insulating compounds of which it forms an ingredient, the writer found that the specific resistance of such compounds is not materially affected until the asphalt constitutes about twenty per cent. of the whole. After that the resistance diminishes rapidly as the proportion of asphalt is increased. This was found to be the case with *all* bituminous matter used by the writer.

None but elastic or flexible asphalts should be used in paints. They combine with nearly all kinds of insulating material, and impart their properties, to a greater or less degree, to all compounds in which they are used. They dissolve freely in almost all solvents, and form the best *protecting* paints known, whether exposed to air or immersed in water. Ordinary chemical agents affect them but slightly or not at all. Owing to the constant changes by oxidization and evaporation of the volatile constituents of the petroleum they contain, they become more brittle, when exposed to air. They can be melted with compatibles and then dissolved, or else dissolved separately and then added to other solutions.

LAMINATED OR DIVIDED IRON AND OTHER METALLIC MASSES IN ELECTROMAGNETIC APPARATUS.—III.

BY

Thos D Lockwood

The French philosopher Masson experimented considerably with induction coils during the years from 1837 to 1842, and published two memoirs upon the subject in the *Annales de Chimie et Phys.*, one by himself only (Vol. lxvi, 1837, pp. 5–28), and the other in conjunction with Breguet, (Vol. iv, 1842, p. 129); and Prof. S. P. Thompson says in his historical notes, introducing the chapter on "Transformers" in his "Dynamo Electric Machinery," that Masson "introduced a bundle of iron wires as a core." Page, however, is silent in this regard, although he speaks of both of Masson's papers; and I have not been able myself to examine the papers to see how Masson stands; I cannot, however, resist the impression that Prof. Thompson must have overlooked this part of the work of Sturgeon, Bachhoffner and Page.

ARAGO.
(*From Scribner's Magazine.*)

In the latter part of 1838, a master mind, gave some little thought, in connection with other matters, to this part of the subject: This was Henry. On November 2, 1838, he presented to the American Philosophical Society a paper on "Electro-Dynamic Induction" which has become a classic. This was recorded in the *Transactions of the Amer. Phil. Soc.* (N. S. Vol. vi, pp. 303–337); and is reprinted in the "Scientific Writings of Joseph Henry." (Vol i, pp. 108–145).

It was also reprinted as early as March, 1840, in *Silliman's American Journal* (Vol. 38, pp. 209–243); and in *Sturgeon's Annals*, (Vol. iv, pp. 281–310, 1840).

Henry details his experiments and shows (Sec. 72) that in using two coils, if one be enclosed in a hollow iron cylinder, it would be screened from the inductive action of the other; as was indeed also the case when a brass cylinder was used. He proceeds (Sec. 76) to show that the dulling effect is probably due to parasitic currents, and as his language cannot be improved on or made more terse, I quote it:—Sec. 76. "Also the same principle appears to have an important bearing on the improvement of the magneto-electrical machine: since the plates of metal which sometimes form the ends of the spool containing the wire, must necessarily diminish the action, and also from experiment of paragraph 72, *the armature itself may circulate a closed current which will interfere with the intensity of the induction in the surrounding wire.* I am inclined to believe that the increased effect observed by Sturgeon, and Callan, when a bundle of wire is substituted for a solid piece of iron *is at least in part due to the interruption of these currents.*"

Thus we see that Henry, at this early date, had seen with the eye of genius these parasitic currents; had foreseen their effect, and had determined how they might be prevented from exercising a damaging influence on the work of magneto machines. Henry then concludes his paper by the following most interesting note:

> "On the evening of the meeting at which my investigations were presented to the Society, my friend Dr. Bache, of the Girard College, gave an account of the investigations of Professor Ettingshausen of Vienna, in reference to the improvement of the magneto-electric machine, some of the results of which he had witnessed at the University of Vienna about a year since. No published account of these experiments has yet reached this country, but it appears that *Professor Ettingshausen had been led to suspect the development of a current in the metal of the keeper of the magneto-electric machine; which diminished the effect of the current in the coil about the keeper, and hence to separate the coil from the keeper, by a ring of wood of some thickness, and afterwards, to prevent entirely the circulation of currents in the keeper, by dividing it into segments, and separating them by a non-conducting material.* I am not aware of the result of this last device, nor whether the mechanical difficulties in its execution were fully overcome.
>
> "It gives me pleasure to learn that the improvements, which I have merely suggested as deductions from the principles of the interference of induced currents, should be in accordance with the experimental conclusions of the above-named philosopher."

This note accompanies the reprint of Henry's paper in *Silliman's Journal*, (March, 1840), as well as in *Sturgeon's Annals of Electricity* (Vol. iv, pp. 309–310).

At this stage, the Genesis of the Lamination appears to have been fully accomplished; and what comes after, concerns its evolution and practical application; for as we have seen, the utility of finely divided iron in appliances comprising electromagnetic apparatus was recognized by Sturgeon, Bachhoffner and Page, and was published by each of these; the efficacy of insulating the divisions from each other had been clearly disclosed by Bachhoffner. One of the reasons for the necessity of division had been suggested by both Sturgeon and Page; and the latter experimentalist, besides reaching his views inductively, as was indeed appropriate considering the subject, had moreover foreshadowed a second reason, namely the prevention of the eddy currents, which was more clearly indicated by Henry and Ettingshausen, this however having already been done in another relation by Faraday. And finally, Ettingshausen had actually reached the point of suggesting the cutting up of an armature core into discs for the elimination of such disturbing currents.

For any who may desire to dip deeper into the early history of the subject as outlined above, it may be of interest to state that an historical summary of the history of induction coils is to be found in the several later editions of Prof. S. P. Thompson's "Dynamo Electric Machinery;" that the two volumes of Prof. J. A. Fleming's excellent work, "The Alternate Current Transformer," are replete with valuable information concerning not merely the history, but the theory and practice, also, of the transformer, including the feature under consideration; and that those who can manage to procure and read the little book of the late Dr. Page on "The History of Induction," will be well repaid for the trouble.

The record of nearly all of the following instances of the evolution and application of the principle of dividing metallic masses exposed to induction, has been personally examined. It is of course probable that many others have occurred; and also that the record of even such as I am here able to give, may likewise be found in other languages, and in many contemporary publications, which I have not found an opportunity to examine.

This record will terminate with the year 1882, for the reasons, first, that by bringing it forward to that date we are enabled to include the famous Hopkinson choking coil patent; and second, because by the year 1882, the principles underlying the division of electromagnetic iron were fully understood, and their application fully appreciated by those "skilled in the art."

That able man, James Prescott Joule, was one of the earliest to observe the value of these principles. As early as December 1838, we find him writing a letter to Sturgeon. (*Annals*, Vol. iii, p. 437) on "An Electromagnetic Engine," in which he describes experiments made with solid and divided cores; and makes the following statement, remarkable for the time, that "the current of electricity produced by a magneto-electric machine is much increased by the insertion of a bundle of iron wires, instead of a solid nucleus of iron, into its coil—a phenomenon evidently occasioned by the peculiar texture of the wires, which allows Mr. Sturgeon's magnetic lines to collapse with greater suddenness."

He returns to the subject with a second letter in March, 1839, which also was published in *Sturgeon's Annals* (Vol. iv, p. 58) and recounts further experiments. In this letter he observes, after stating his results, that "the above results will not appear surprising if we consider, first, the resistance which iron presents to the induction of magnetism; and second, how very much the induction is exalted by the completion of the *ferruginous circuit*," which observation is most striking, since it comprehends the two modern doctrines of magnetic permeability and the magnetic circuit.

A British patent was granted on Sept. 24, 1840, to Henry Pinkus, which includes among other things "an electromagnetic break (meaning I suppose *brake*), in which a flexible armature of *thin laminated* plates lying on one another is attracted to an electromagnet." In this year also, we find a well-thought-out, and well-written paper, "On Electromagnetic Coil Machines," by Thomas Wright, published in *Sturgeon's Annals of Electricity* (Nov. 1840, Vol. v, pp. 349—352), which recounts many interesting experiments with induction coils, having coils made up of sheet iron strips, and hoop iron.

In 1843 we once more hear from Joule. On August 21 of that year, he read before the British Association a paper on "The Calorific Effects of Magneto-Electricity, and on the Mechanical Value of Heat," which later was published (*Phil. Mag.*, series 3, Vol. xxiii, pp. 263, 347 and 435). In this paper he described and used an electromagnet whose core was composed of "six plates of annealed hoop iron, each 8 inches long, $1\frac{1}{8}$ inch broad and $\frac{1}{16}$ inch thick," these being "insulated from each other by slips of oiled paper." He recognizes the existence of eddy currents, and says, speaking of the above magnet: "Although any considerable development of electrical currents in the iron of the revolving electromagnet was prevented by its disposition in a number of thin plates insulated from each other, I apprehended that they might under a powerful inductive influence exist separately in each plate to such an extent as to produce an appreciable quantity of heat."

A text book entitled "A Manual of Electricity, Magnetism and Meteorology," was, in 1844, written by Dr. Dionysius Lardner. In its second volume (p. 516) the author refers to Bachhoffner's discovery of the superiority of iron wire cores; says that Dr. Golding Bird and others promptly adopted them; that electromagnets are since made that way; and that Joule prefers square to round fibres.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed, and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XV. NEW YORK, JANUARY 18, 1893. No. 246.

THE ELECTRICAL CONGRESS PROGRAMME.

INTERNATIONAL congresses are now the order of the day, and electricity has certainly had a lion's share among these gatherings in various countries, whither delegates have been attracted by electrical exhibitions. Indeed, probably few other branches of science could have got together such meetings of representative men. And now, close upon the late Frankfort Congress, we are already preparing for the one at Chicago. That such an early reassembling of electricians is necessary to determine doubtful questions and fix new units and names therefor, we believe to be beyond a doubt, and for proof we need only to glance at the provisional programmes submitted by the General Congress Committee of the American Institute of Electrical Engineers and by the corresponding English Committee. Though much good work has been done by previous Congresses, the advancing science has made it imperative to bring more strictly within the bounds of accuracy numerous definitions of electrical and magnetic quantities, to assign names for desirable additional units, and a dozen other questions of the first importance to the working electrician as well as to the scientist. Without entering here into a specific discussion of the committee's programme, which we print elsewhere in this issue, we wish to draw special attention to the excellent suggestion that an International Congress is the place to close, but not to open, a discussion on questions involving international agreement. Without wishing in any way to reflect on the work of previous congresses, which have done much good, we may remind those who have attended such gatherings in the past that even with the best intentions the time given to the subjects in hand is so brief and the members are so liable to be drawn away from the real business of such congresses by the many hospitalities extended on these occasions, that deliberate concerted action is almost out of the question. Hence the necessity of submitting to the members of the coming congress, the questions to be determined, in such a form that they can be acted upon with little if any discussion. Another point upon which too much stress can not be laid is the selection of official delegates by governments and representative scientific societies to determine the subjects to be definitely acted upon. It goes without saying that there can be no permanent international character endowed or conferred upon any unit for instance, without the action of a majority of international delegates. In other words, we hold that a general congress such as that to be held in Chicago, and open to everyone upon payment of a small fee, is not the body—unless divided into sections—to formulate, but merely to ratify, propositions submitted by competent authorities. The congress will probably consist therefore of an upper and a lower house. Our own countrymen will naturally constitute the large majority of the lower house—open to all,—and an "international vote" there would have but one result; it would be "patriotic" as it would in any other country under similar conditions. All of the committee's suggestions and recommendations are deserving of the most serious consideration, not the least of which is the call for open discussion by all of the propositions submitted. We shall be glad to aid in this work by opening our columns to those desiring to take up questions connected with the next congress.

Space At The World's Fair.

EXTRAORDINARY statements have been appearing lately in the Chicago newspapers as to the delay and disappointment in allotting space at the World's Fair. One article describes Director General Davis as imprisoning various chiefs of department in his office for two or three days until they had made some sort of disposition of the problems involved in dividing an utterly inadequate amount of floor space among thousands of eager applicants. Meantime, we are glad to be able to publish in this issue complete diagrams of Electricity Building, showing the chief allotments made there by Prof. Barrett and Dr. Hornsby. It is too much to expect that everybody will be satisfied, but credit must be given for an effort to do the best that the circumstances permit. It is interesting to note that foreign nations, particularly France and Germany, will be fairly well represented in this Building.

The "Deadly" Flagpole.

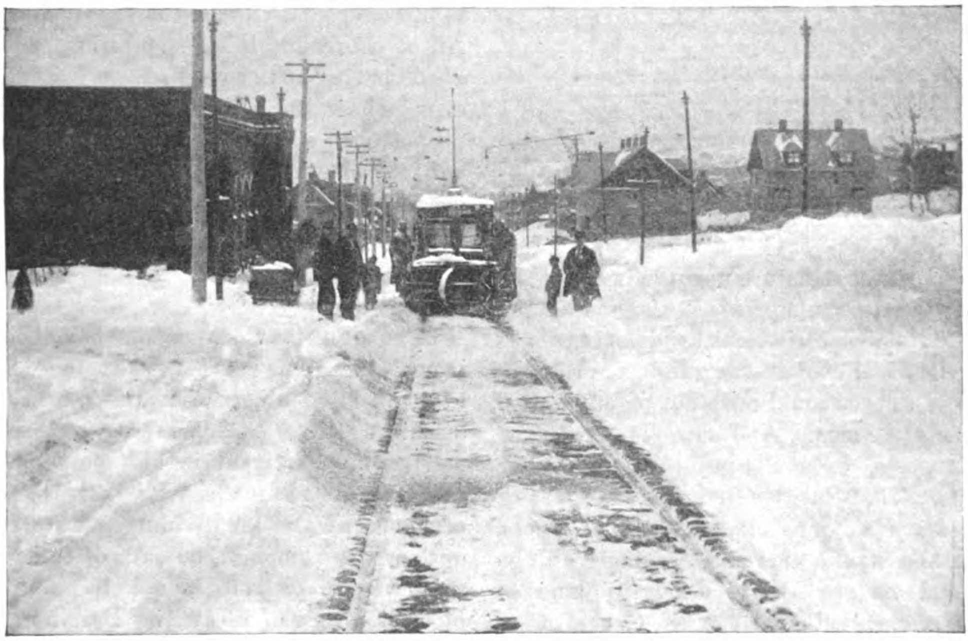
WE cannot refrain from expressing our sympathy with the crusade that Mr. David McAdam, of this city, has just began against the flagpoles that cap so many buildings. He says they are "a standing menace to life and limb," and that when thrown from the top of a building they are capable of doing "incalculable damage." This is, no doubt, true. A flagpole, like a trolley pole, is intensely deadly, even when standing stiff upright, 150 feet above the ground; and it is only due to the forebearance of the public that we so rarely hear of accidents with either.

ELECTRIC RAILWAY DEPARTMENT.

THE TROLLEY IN THE RECENT SNOW STORMS.

New York Rapid Transit, January, 1893.

IT is admitted on all sides that the present winter is the severest since 1888, while the snow has been as heavy and continuous as at any time during the past decade. Such a winter, therefore, and such a week as the past, should afford a good test of the ability of trolley cars to maintain their running schedule in wintry weather, and it is satisfactory to note that they have almost everywhere responded nobly to the call upon them. The worst interruption appears to have occurred at Toledo, Ohio, where about 100 motor cars got stalled or were unable to run out; but as the trains on 20 railways entering Toledo were from 5 to 15 hours late, it may be inferred that the ordeal was one before which everything had to succumb temporarily. In Brooklyn, N. Y., the trolley cars were the only ones running on time, while the Brooklyn elevated road and the horse cars were subject to great delay and the bridge cable service broke down. In New York city, the suburban trolley cars beyond the Harlem River ran very well indeed, but as our little illustration shows, the horse cars had a hard time. The sketch is reproduced from the *New York World*, which is opposing trolley cars and an extension of the elevated facilities, tooth and nail and tongue; so that our readers may infer what kind of rapid transit that journal wants New Yorkers to have.



CLEANING SNOW FROM TRACK WITH ELECTRIC SWEEPER.

In Boston the service of the West End road was maintained admirably. Mr. Dumoulin, the road's vigilant electrical engineer, informs us that they had out 80 snow-plows and sweepers. Each of these is run by two 25 h. p. motors, and the entire number work over about 160 miles of trolley system. They are sent out the moment snow comes on, with the result that as in the present instance, not a single trip was lost. A similar report comes from Brockton, Mass., and the local *Enterprise* says: "The officers of the electric road are deserving of all praise for the excellent manner in which they kept the tracks clear during the storm last week."

But perhaps the most encouraging report is that which comes from Philadelphia, where the trolley has been quarantined as though it were the cholera. The system is still young in the city, but the *Philadelphia Record*, one of the most progressive and public-spirited papers in the country says: "The superiority of the electric trolley lines in this regard was marked. All through the storm the cars on the Catherine and Bainbridge trolley system ran smoothly and on schedule time; and in Camden, where the horse cars were hopelessly blocked, the Market street trolley cars kept running without interruption. The storm has demonstrated the practical utility, value and reliability of the trolley system by the application of the logic of convincing and irrefutable facts. A system of street passenger transportation that could not be broken down even under the strain of last Thursday's storm may safely be commended to general use and acceptance."

ELECTRICAL MAIL TRANSPORTATION IN CITIES.

IN our last issue, the subject of handling mail by trolley cars was broadly discussed. The topic it a very important one, with many sides of interest, and tempting to the inventor. A few further details of what is being done in other directions may be given.

An act of congress, dated July 13, 1892, authorizes the Post-Master General "to examine into the subject of a more rapid dispatch of mail matter between large cities and post-office stations and transportation terminals located in large cities by means of pneumatic tubes or other systems," with the view of ascertaining the cost and advantages of the same. Accordingly Postmaster General Wanamaker caused advertisements to be inserted in various newspapers calling on all persons who were the inventors, or had the control of any pneumatic tube or other device suitable for the proposed service to present a full description of the same, which must include the kind and quantity of the motive power used.

The commission appointed by Postmaster General Wanamaker to examine the different systems, and consisting of Second Assistant Postmaster Bell, Third Assistant Postmaster General Hazen, and Mr. Maynard, of the inspection division of the post-office department, has reported in favor of the United States Automatic Dispatch Company of this city, which has agreed to put its system in operation between Brooklyn and New York and operate it for one year at its own expense, provided the postal authorities will accept it afterward if it proves satisfactory and to grant to the government the right to use its system outside of New York and Brooklyn at an annual rental of $150,000.

The system of which Mr. Andrew Bryson, of this city, is the inventor, is designed to be used not only in and between closely-adjacent large cities, but once its practicability has been established to the satisfaction of the postal authorities there is no reason why it should not be extended so as to connect cities miles apart and, eventually, over the whole country.

In this system the mail matter will be sent through a metal tube 16 inches square. The mail carrier is a steel box with closed ends and latticed sides. It is 5 feet long and about 14 x 14 inches square, thus allowing a small margin on all sides when in the tube.

For switching off carriers at intermediate stations, Mr. Bryson uses a guide rail fastened to the side of the tube, which engages with an arm fixed to the side of the carrier. At each sub-station on the line there is a guide rail at a height corresponding with a notch or slot and no two guide rails are of the same height. When a carrier is loaded with mail for a certain station the dispatcher places the engaging arm in the slot corresponding with the guide rail at that station. The carrier is then sent off. The engaging arm cannot engage with any other guide rail but the one it is intended for.

Each carrier has its individual motor taking current from wires at the bottom of the conduit.

The action of closing the dispatcher energizes the motor which starts off on its journey. On approaching the receiving station the passage of the carrier automatically cuts off the current and the carrier slows up. The approach of a carrier is signaled by a bell so that the possibility of starting another carrier ahead of the approaching one and thus running a risk of a rear end collision before the carrier last started has attained full headway is avoided.

Permission has now been applied for to lay conduits from the New York and Brooklyn post-offices to the approaches of the Brooklyn Bridge, and to suspend an aerial conduit beneath the Bridge itself. The Postmaster General has already granted the company the right to enter the two post-office buildings.

Among other devices for supporting pneumatic tubes, electric wires, etc., is one owned by the Aerial Conduit Co. of this city, the patents of which were taken out by Messrs. O. F. Smith, and A. A. Knudson; one of them as far back as 1881. This conduit has lately undergone slight changes by Mr. Knudson so that it is now adapted for transporting mail, or express-packages either by pneumatic tube or by electric motor.

A curious development of the situation has been the struggle for the control of certain stock in the Porte Electric system, of which several descriptions have been given in the THE ELECTRICAL ENGINEER. The idea is to handle mail, etc., by means of carriers which are of magnetic material and are sucked inductively through a succession of coils. There was great excitement at the Real Estate Exchange, in this city on Jan. 10, when Auctioneer H. W. Donald, of R. V. Harnett & Co., put up for sale 20,500 shares of the United States Porte Electric Company. J. Sidney Goldsmith, a broker, and Lawyer H. D. Loomis, beginning at $10, in a few minutes raised the bid to $1,800,000 for the lot.

Mr. Goldsmith purchased the stock, and he had no sooner done it than he was served with a notice from Charles F. James, the secretary and treasurer of the company, that the International Porte Electric Company, which had offered the stock for sale, had no right to it, and that purchasers buying it bought subject to his claim against it. The auctioneers have not delivered the stock and will not until the matter is settled. They claim about $9,000 commission on the sale.

Mr. James said that there was a new element in the company that was trying to push the old out. The sale was devised by one of these who had given bad advice to the other stockholders. The stock had been put up for sale by this element, without properly notifying or consulting other shareholders. Mr. James said he had been notified only the evening before. But he had had ample time, though, to have a legal notice served upon the would-be purchaser who wanted to get control of the company. Mr. James seemed to doubt that the sale would be effected in view of his notice. H. D. Hotchkiss, who represented the United States Porte Electric Company, said at the sale that the bid of Mr. Goldsmith had not been made in good faith.

THE CHICAGO & ST. LOUIS ELECTRIC RAILROAD BEFORE CONGRESS.

THE following despatch appeared in the *N. Y. Herald* of Jan. 13: Washington, Jan. 12, 1893.—Parties interested in the projected electric railroad between Chicago and St. Louis appeared before the Senate Committee on Commerce yesterday and endeavored to show that the government should permit them to import necessary construction material free of duty in consideration of building a pioneer line which shall whisk passengers and mail to and from Chicago and St. Louis at a speed of over a hundred miles an hour.

Wellington Adams and others represented the interests of the company, while the General Electric Company was represented by Eugene H. Lewis, of New York, as counsel Mr. Adams made a strong argument for the project. He said that the company was hampered in its operations by the hostility of the General Electric Company, against which he had brought suit for infringement of patents relating to motors, and there was reason to doubt whether the necessary electric machinery could be built in this country in time to have the road in operation during the World's Columbian Exposition.

Mr. Lewis opposed the bill. He saw no reason for the special exemption to be granted the Chicago and St. Louis Electric Railroad, as his company could and did manufacture electrical goods as well and as cheaply as any concern in any other country, in proof of which he asserted that they were supplying the plant for 18 electric roads building in Europe. He questioned the honesty of purpose of the new company, which, he said, never intended to really build a railroad, and he asserted that they had approached the General Electric Company with an offer to pay for electric plant with stock and bonds.

This statement led to some sharp sparring between the parties present, in which pointed references were made to the existence of a great trust in electrical manufactures, and finally Mr. Lewis admitted that other electric roads had made like propositions, which had been accepted. The committee took the bill under consideration.

FIGURES OF STREET RAILWAY TRAVEL IN BROOKLYN.

THE population of Brooklyn this year has not increased any more than in previous years, and the elevated railway service has been extended, but, nevertheless, the surface roads carried during 1892 over 15,000,000 more passengers than they did in 1891. The Brooklyn City Road headed the list with 78,500,000 passengers, an increase of 4,800,000. The Atlantic Avenue Company came next with 16,249,080, but its increase was 6,200,000, and its percentage very much greater than that of the larger road. This remarkable increase in travel in one year was undoubtedly the reason why the new syndicate that has purchased the road was willing to pay $250 a share for its stock.

These figures ought to show the fallacy of the old idea that the building of the elevated roads would ruin the surface roads. The latter have gone on doing more business than ever since the former were completed, and it really seems that the more roads there are the more people ride instead of walk.

This increase in the business of the surface railroads has not injured the elevated at all; in fact, the Brooklyn elevated did last year the biggest business of any year since its organization, and, for the first time, came out of the struggle with a surplus. It carried 37,315,180 passengers, as against 34,424,708 in 1891; its gross earnings were $1,901 671.77, and its operating expenses $1,072,526.26. This left net earnings of $829,145.51, and after the interest on bonds and other fixed charges were paid, amounting to $711,089.59, there was a surplus of $118,055.92.

THE NOISE MADE BY SOME TROLLEY CARS.

A CORRESPONDENT in Baltimore calls our attention to the very unnecessary noise made by some trolley cars, and encloses the following item from a Baltimore newspaper:—

> Mr. John Henry Keene, Jr. wrote to Mayor Latrobe yesterday a formal notification of proposed legal action on account of the Central Railway Company. The cars pass the residence of Mr. Keene, corner of St. Paul and Preston streets. The letter is in part as follows:
>
> "Inasmuch as express notice is essential to maintain an action at law for the recovery of damages against municipal corporations on account of nuisances, on my own behalf, as well as that of all other persons who have suffered or hereafter may suffer special damage, I notify you as Mayor of the city of Baltimore that the Central Railway, as run and constructed from the commencement to the termination of its route and contiguous thereto, is a public and private nuisance, nothwithstanding its color or warrant of lawful authority by reason either of the license of the city ordinance or the confirmation of this license by an act of the Legislature."
>
> After discussing the legal aspects of the case Mr. Keene says: "I give you further notice that the nuisance of which I complain exceeds the extravaganzas of fiction, and equals the barbarous cruelties of the middle ages. This nuisance is not a mere visionary picture; it is a stern reality—a flesh and blood fact with color in its cheeks. It is a system of rapid transit by hissing monsters, often hurled at frightful rates of speed, thumping and bumping at every step. They ascend and descend every grade with Babylonish howls. The air rings with the shrieks of their gongs, and by day and by night a flesh-creeping saw-mill buzz, with showers of electric sparks, mark their struggling, groaning course through the highways of a densely populated city.
>
> "To picture the horrors of this nuisance requires the genius of the author of the 'Inferno,' and it affords a most significant illustration of what our Court of Appeals has called the subjection of the streets to 'extraordinary servitudes.' No sooner does one of these furies disappear than lo! another follows hard and fast upon its heels. Often two pass each other upon their double tracks, and the air for blocks around is filled with the unearthly din of their motors. What aggravates the nuisance is that the reign of terror commences at early dawn and lasts until long after the midnight hour. In consequence of the vibration and concussion of the air produced by this nuisance at every few minutes night and day, houses are shaken, doors and walls tremble, windows creak and chandeliers and glass shiver. Strong men, sick women and children are alike prostrated, their nervous systems shattered and their health undermined, notwithstanding that they have bought their houses upon the sacred trust that the city they support by taxes has the power and authority, and stands charged with the duty and obligation, of removing and preventing whatever is instrinsically a nuisance and essentially deprives the owner of premises abutting upon a highway of the enjoyment, comfort and protection of his fireside."

Though the above account, I must honestly admit, is *slightly* exaggerated, writes our correspondent, the motor's weird complaint can sometimes be heard for blocks and the effect on the nerves of even an ordinarily sensitive person is startling I assure you. To illustrate the matter take for example: A car is starting after taking a passenger aboard. The motor-man with eagle eye carefully scans the roadbed and with one hand on the brake and the other on the controller prepares to get in his deadly work. Imperceptibly the latter moves and the car starts so slowly as to suggest that it were moved by unseen spirits; and then with a lightninglike movement the controller is thrown to the full speed position. The motors roar and howl, the car trembles violently, the peripheries of the wheel become circles of light, the grinding of the wheels on the rail through insufficient tractive effect produces a sound similar to the simultaneous operation of a number of coffee mills; and thus does the electric car proceed on its way rejoicing, truly winning its name of a thunderbolt of Jove. I hope that in the future, by proper management and care it will be impossible to elicit any other expression from the people than one of praise for the *only* system of rapid transit. Our friends reveal our faults to us, and make us haste to do better in the future.

THE COST OF TRACK SPRINKLING AND CLEANING.

The question of transfers between the Central and Rapid Transit Co.'s in Peoria, Ill., has not been decided as yet. There have been several meetings between the city council and Manager Findley, of the Central. The railroad company will give transfers if the council will remove the three per cent. levy it is to receive in five years. The Central Company through Manager Findley gave recently an estimate of the cost of sprinkling the tracks, etc. His report is as follows:—

The Central R. R. Co. own 44,752 feet of double track and 6,479 feet of single track, or a total of 95,983 feet of single track. Allowing seven feet for the width to be cleaned for a single track, there would be 671,881 square feet of surface to be cleaned and swept, which is equal to 74,653 square yards. Estimating the cost for sweeping to be $1.15 per 1,000 square yards, being the price paid by the city, it would cost the railroad company $85 85 for each time the tracks were cleaned. Allow for cleaning the tracks once every week, the sum total per year would be $4,464.20.

If the city furnish the water, the cost for teams and labor to do the sprinkling would be about $15 per day. Estimating that it would be necessary to sprinkle 200 days each year, the cost per year would be $3,000; or total cost for cleaning and sprinkling each year $7,464.20.

The Rapid Transit Co., of Peoria, own 14,665 feet of single track; figured on the same basis the total cost for cleaning and sprinkling would be about $1,250 per year.

From this it would seem that the railroad company are ready to clean and sprinkle their tracks and throw in transfers, to get off the three per cent. levy. The cleaning and sprinkling to commence at once, while the levy does not begin for five years.

THE VALUE OF A SLIDING CONTACT TROLLEY.

Mr. Louis B. Van Nuys writes us from Peoria, Ill., that during a recent severe sleet storm there, the electric lines managed to run by taking the trolley wheels out of the trolley poles and letting the forks that hold them slide along the wire instead!

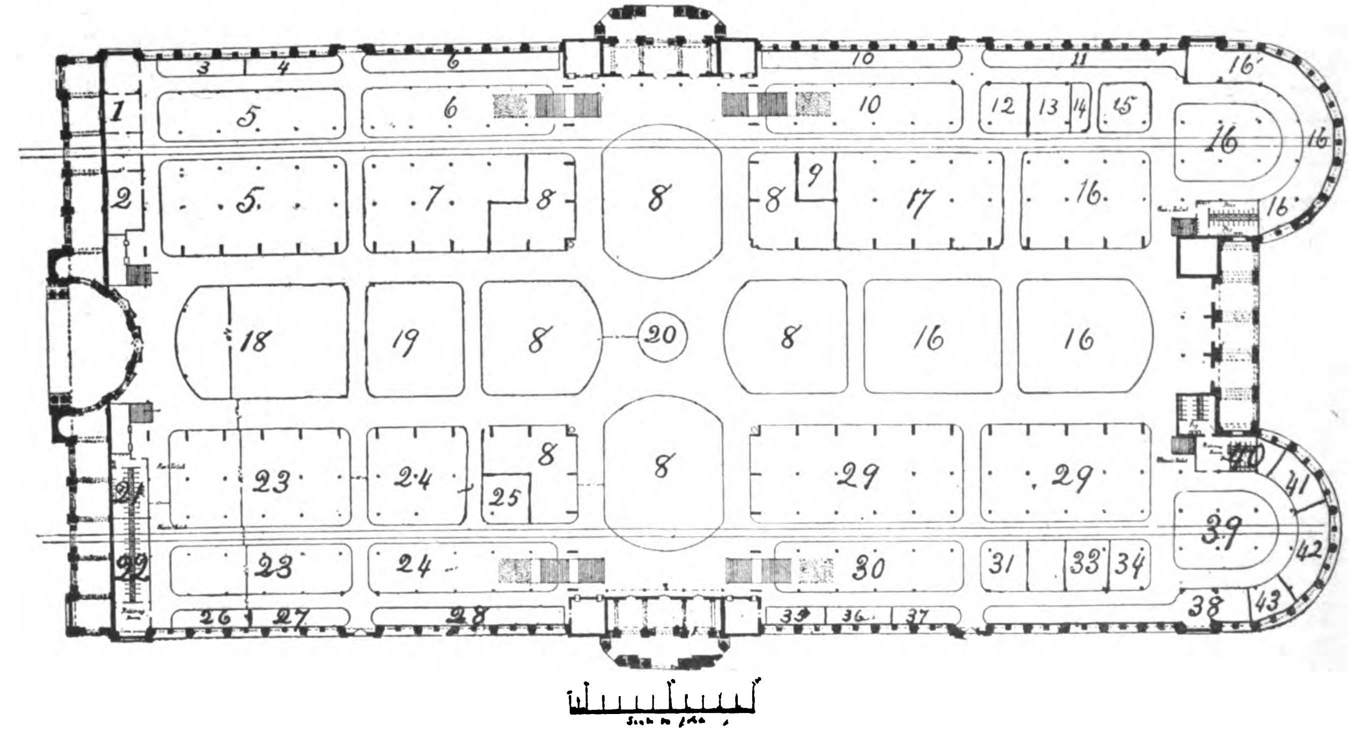
ELECTRIC RAILWAY GROWTH.

During last year the number of electric railways increased from 385 to 469, the capital stock from $155,087,973 to $205,870,000, and the mileage from 3,916 to 5,446 miles.

WORLD'S FAIR DEPARTMENT.

ALLOTTING SPACE IN ELECTRICITY BUILDING.

We show herewith plans of the ground floor and galleries of Electricity Building, with the names of the exhibitors to whom space has been allotted. The numbers on the plans correspond with the references at the foot, and it will thus be easy to understand the disposition of the exhibits.



1. Crocker Wheeler Electric Co.
2. Jenney Electric Motor Co.
3. Hanson & Van Winkle.
4. Germania Electric Co.
5. { Brush Electric Co.
   Swan Lamp Co.
   Short System of Railways.
6. National Electric Co.
7. Ft. Wayne Electric Co.
8. General Electric Co.
9. Heisler Electric Co.
10. Thomson Welding Co.
11. Italy.
12. Mexico.
13. Spain.
14. Russia.
15. Belgium.
16. France.
17. England.
18. Bell Telephone Co.
19 Detroit Electrical Works.
20. Phœnix Glass Co.
21. C. & C. Motor Co.
22. Sperry Elec. Mining Machine Co.
23. Western Electric Co.
24. Westinghouse Electric Co
25. Excelsior Electric Co
26. La Roche Electric Co.
27. Hornell Iron Works.
28. Eddy Electric Co.
29. Germany.
30. Electric Forging Co.
31. Belknap Motor Co.
32. (Not assigned).
33. Arnold Electric Co.
34. A. C. Mather.
35. Schieren Belting Co.
36. Munson Belting Co.
37. Page Belting Co.
38. The E. S. Greely & Co.
39. N. Y. Insulated Wire Co.
40. Zucker-Leavitt Chemical Co.
41. Riker Motor Co.
42. Perkins Lamp Co.
43. Akron Electric Co.

The Allotment of Space, Ground Floor, Electricity Building, World's Fair.

We print also below, the revised rules and regulations for exhibitors now adopted and put in force by the Department of Electricity.

RULES DEPARTMENT OF ELECTRICITY.

Rule 1.—Applicants for space in this Department are requested to furnish the following information as nearly as possible:

First. A drawing to the scale of ¼ inch to the foot, showing size of space desired and general distribution of articles to be exhibited, also aisles (if any among exhibits. Express length, breadth, etc., in feet and inches.

Second. State whether current for motors, lamps, or other devices is required, specifying quantity and potential in volts and amperes.

Third. If power for operating machinery is required, state number of horse-power desired.

The above information is absolutely necessary for the proper allotment of space.

Rule 2.—Applicants accepting space must agree to occupy it in accordance with the rules and regulations, and are requested to give earliest possible notice if they decide not to exhibit. Whenever circumstances will admit, exhibitors are requested to install exhibits in glass cases.

Rule 3.—No exhibitor can make exhibits in other than his own space without obtaining the written permission to do so from the Chief of the Department.

Rule 4.—No exhibitor will be allowed to arrange his exhibit in a way to occasion inconvenience or affect the display of other exhibitors.

Rule 5.—The floor of the Electrical Building is designed to sustain a weight of 150 pounds per square foot. Any exhibit requiring an extra support, in the judgment of the Chief of the Department, must be furnished with satisfactory support or foundation at exhibitor's expense.

Rule 6.—All platforms, railings, counters, signs, partitions and showcases must be erected at exhibitor's expense and shall not exceed dimensions given below. All designs for the above with location of same in exhibitor's space must be submitted to the Chief of the Department for his written approval before installation is begun.

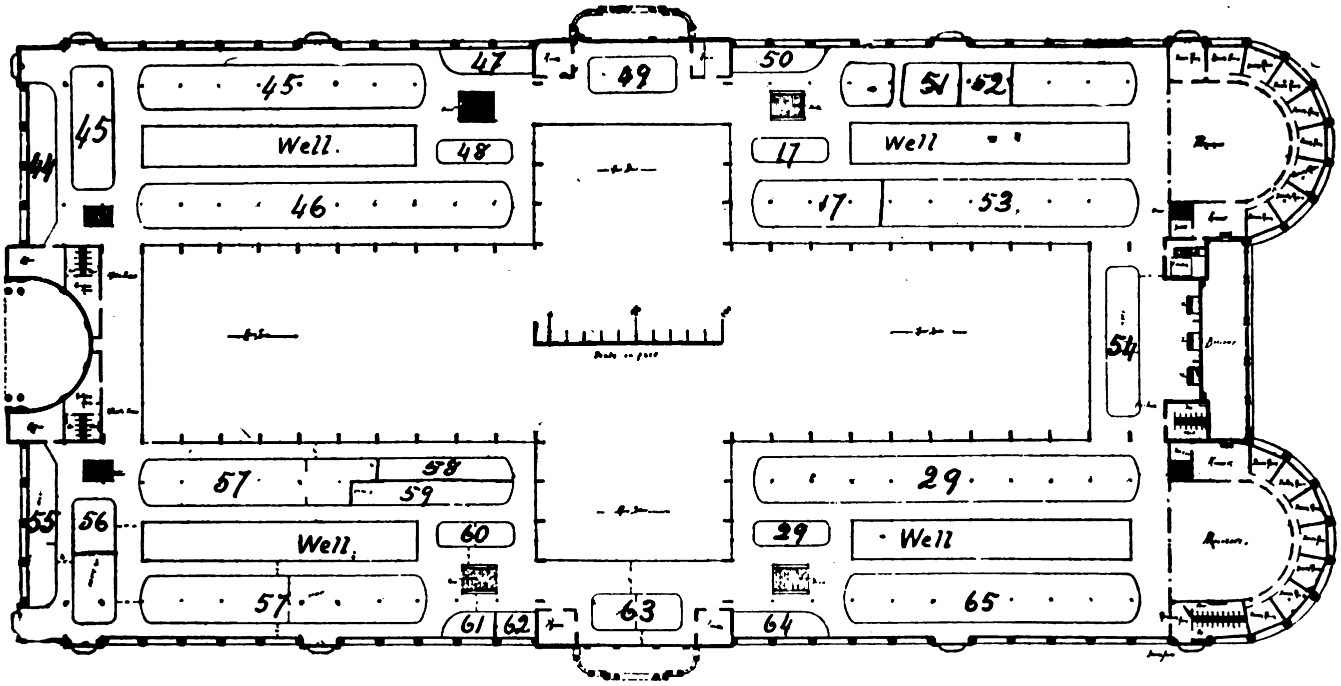
Showcases shall not be higher than 15 feet above the floor of the main aisles.

Counters shall not be higher than 2 feet 10 inches above the floor of the main aisles.

Railings may be erected, but must be of a uniform height of 2 feet 6 inches, and subject to the approval of the Chief, as in *Rule* 8.

Platforms will be allowed only in certain parts of the building. All exhibitors wishing platforms to cover their space must build them to a uniform height of 8 inches.

Partitions will be allowed only in certain parts of the building, and in all cases must not exceed 15 feet in height, and must be approved in writing by the Chief of the Department before their erection is begun.



44. E. Berliner.
45. Miscellaneous.
46. Electrical Apparatus.
47. Lafferty & Holmes.
48. McIntosh Battery Co.
49. Dayton Fan & Motor Co.
50. Elisha Gray.
51. Austria.
52. Italy.
53. Canada.
54. Electrical Supply Co.
55. Electric Specialties.
56. Weston Elect. Instrument Co.
57. Wire Exhibits.
58. Detroit Electrical Works.
59. Central Electric Co.
60. Gamewell Fire Alarm.
61. Washburn & Moen.
62. American Storage Battery Co.
63. Queen & Co.
64. Western Union Telegraph Co.
65. Testing Instruments.

The Allotment of Space, Galleries, Electricity Building, World's Fair.

Signs must be ornamental in character, and designs for same must be submitted to the Chief of the Department for his written approval. No signs will be allowed to extend beyond the limits of the exhibitor's space, nor will signs of muslin, linen, canvas or paper be accepted. The Chief of the Department reserves the right to remove any signs that may be objectionable.

Rule 7.—All exhibits of machinery in motion must be protected by ornamental railing of a uniform height of 2 feet 6 inches, and all designs for railings must be submitted to the Chief of the Department for his written approval.

Rule 8.—No fire will be allowed in the Electrical Building except by the written permission of the Chief of the Department; oils and inflammable material will be allowed only in quantities sufficient for one day's use; suitable storage will be provided for the same.

Rule 9.—Exhibitors requiring power in the Electrical Building will have to furnish the necessary countershafting, pulleys, hangers, etc., at their own expense. Electric motors only will be allowed for moving machinery in this building, and must be furnished at the expense of the exhibitor.

Shafting and motors will be under the care of the exhibitor requiring them, but can be erected only on receipt of a permit from the Chief of the Department. Exhibitors must arrange their exhibits in such a manner as to require a minimum amount of shafting by using motors connected or belted to their machinery direct.

Rule 10.—Exhibitors may employ watchmen to take care of their machinery and exhibits at night, but such watchmen will be subject to the approval of the Chief of the Department.

Rule 11.—Exhibitors will be required to have their space clean, and all rubbish swept into the aisles within one hour after the close of the Exposition at night. In cases where this rule is not complied with the work will be done by the Department and charged to the exhibitor. No sweeping will be allowed during the hours when the Exposition is open.

Rule 12.—The distribution of cards, circulars, pamphlets or samples about the building or its vicinity, will not be permitted under any circumstances. Exhibitors can distribute such articles only from their own space, but will not be allowed to solicit their acceptance.

Rule 13.—Exhibitors will be required to attach to each exhibit a printed or type-written description in the English language, of the use and operation of the object exhibited for the information of the public.

Rule 14.—Exhibitors or their agents will be furnished by the department with duplicate cards, upon which must be the name and description and the catalogue number of each article entered for exhibition. These will be countersigned on receipt of articles into the Exposition. One of these cards shall be conspicuously attached to the article described, the other to be retained by the exhibitor to serve as his order for the article at the close of the Exposition.

MISCELLANEOUS.

AN IDEAL GUBERNATORIAL CANDIDATE.

Few men in the field of mechanical engineering are better known to electrical engineers than Mr. G. C. Sims, of the Armington & Sims Engine Co., of Providence, and chairman of the Electrical Committee of the National Commission on the World's Fair. They will find much to approve in the following from the *Boston Herald*, on the Rhode Island governorship:

At present, the Democrats are not talking much about their gubernatorial candidate. But among the thinkers it has been suggested that, if the party wishes to win on a popular vote, it can do so by nominating Hon. Gardiner C. Sims.

Mr. Sims has heretofore declined to take an active part in politics. Time and again have honors been proffered him; but he has invariably said that his business engagements were such that he could not spare the time the duties of office would demand. This is a time, however, it is said by his friends, when he should make a sacrifice, for he can just as surely be elected as the day of election rolls around. He would command the entire independent vote of the state. The independent press of the state would give him hearty support. The Democratic party would indorse him to a man, and there would be a good many Republicans, who admire the man for his sterling character, who would gladly vote for him.

Gardiner C. Sims' name is synonymous with positive good faith, honor, business integrity and everything that is above board and goes to make up a thoroughly reputable citizen. He is an ideal candidate, and he would give to the state an intelligent, progressive and aggressive administration. He is one of the foremost members of the Commercial Club, the organization which is doing so much good in awakening public interest in the affairs which go to make up a good government and a live community.

INSULATION RESISTANCE OF COTTON AND SILK-COVERED-WIRES.—A CORRECTION.

Through an error of the engraver the designations of the curves in Fig. 7 of the above article appearing in the Engineer of Dec. 28, 1892, were transposed. As the text clearly shows, the upper curve should be marked "Double Cotton Shellacked," and the lower, "Single Cotton Shellacked." Also in the line immediately above the Fig. 8 on p. 615, in the same article, the infinity sign ∞ was inadvertently turned up by the printer so as to read as the figure 8.

THE UTILIZATION OF NIAGARA.[1]—I.

BY PROF. GEORGE FORBES, F.R.S.

THE situation of Niagara Falls is peculiarly favorable, both from the engineering and commercial point of view. As a source of water power, it stands almost unrivaled, not only on account of the enormous volume of water, and the considerable height of its fall, but also on account of the unvarying volume which is continually flowing. From a commercial point of view the situation of the Falls is perhaps unique, and the originators of this enterprise can find much to support their views—that they are entitled to look forward to the prospect of founding, in the immediate vicinity of the Falls, a manufacturing town greater than any which exists in the United States. This sounds a somewhat too enthusiastic view of the matter to those who are accustomed only to a comparatively slow rate of progress in European affairs. But when one sees a town like Minneapolis springing up to its present proportions in the course of a few decades, due to the development of some fifteen thousand h. p., used by the water-wheels there; and the industries which have sprung up to utilize the water-power developed at Holyoke, Mass., one can imagine the effect that the utilization of Niagara Falls will have on the prosperity of the locality. The great developments of electrical industry, either from a manufacturing, mining, or agricultural point of view are in the far West; and the enormous group of navigable lakes form a natural highway for the transport of raw products, most of which require the expenditure of power to convert them into articles of commerce. Niagara Falls being situated at the eastern extremity of these lakes, which is the end nearest to the consumers, they evidently occupy an advantageous position. Three principal lines of railway pass in the immediate vicinity of the land owned by the company which is developing the power of Niagara Falls, and a terminal railway has already been built by them to connect the different parts of their property with these three lines of railway. The Erie Canal also passes from this point to the Hudson River and thence to New York, and Niagara Falls being actually on the frontier of Canada open up the whole of that country to commerce. Thus we see that both from an engineering and commercial point of view this situation is peculiarly favorable to a rapid development.

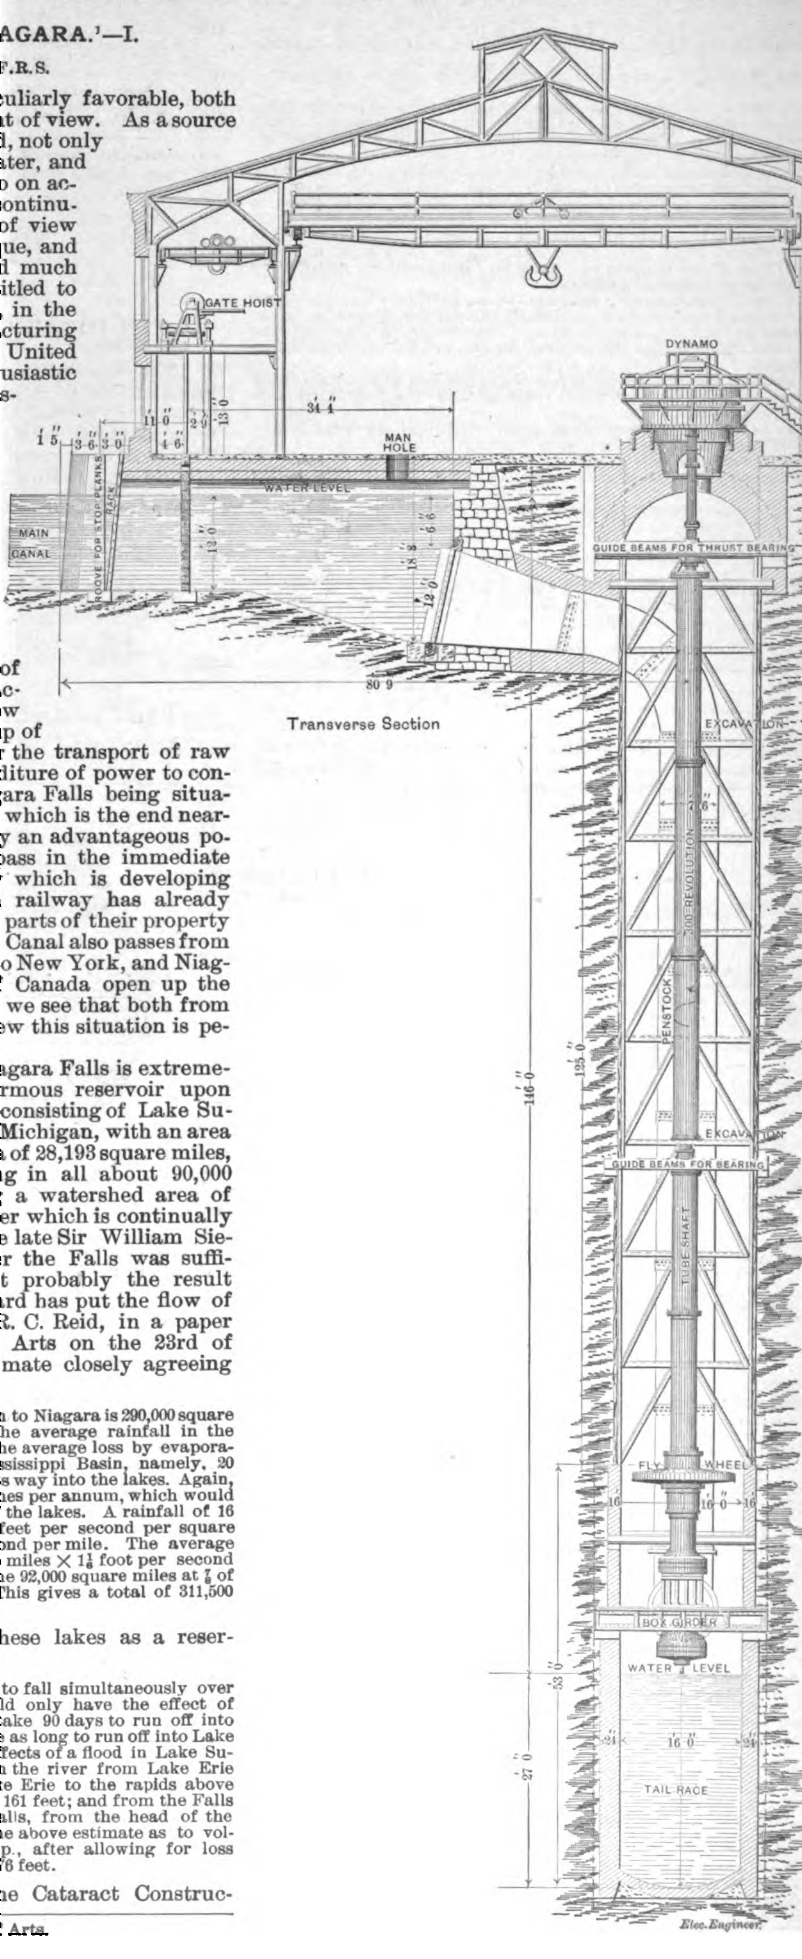
The reason why the flow of water at Niagara Falls is extremely regular, is that we have such an enormous reservoir upon which to draw for our supply, this reservoir consisting of Lake Superior, with an area of 33,517 square miles, Michigan, with an area of 24,200 square miles, Huron, with an area of 28,193 square miles, and Erie, with an area of 11,574 miles, being in all about 90,000 square miles of reservoir surface, draining a watershed area of 2,411,235 square miles. The volume of water which is continually flowing has been variously estimated. The late Sir William Siemens considered that the flow of water over the Falls was sufficient to develop 16,000,000 of h. p., but probably the result is considerably less. The Lake Survey Board has put the flow of water at 265,000 cubic feet a second. Mr. R. C. Reid, in a paper read before the Royal Scottish Society of Arts on the 23rd of March, 1885, has made an independent estimate closely agreeing with this. He says:—

> The drainage area of the whole Lake Basin down to Niagara is 290,000 square miles, and of that there is of lake surface 92,000. The average rainfall in the lake district may be taken at 36 inches, and taking the average loss by evaporation and absorption at the figures given for the Mississippi Basin, namely, 20 inches, there will be 16 inches of rainfall that finds its way into the lakes. Again, on the surface of still water the evaporation is 24 inches per annum, which would leave 12 inches of rainfall collected on the surface of the lakes. A rainfall of 16 inches is very nearly equal to an average flow of $1\frac{1}{8}$ feet per second per square mile, while 12 inches would equal $\frac{7}{8}$ of a foot per second per mile. The average flow will therefore be—from the land, 198,000 square miles × $1\frac{1}{8}$ foot per second per mile, giving 231,000 feet per second; and from the 92,000 square miles at $\frac{7}{8}$ of a foot per second per mile, 80,500 feet per second. This gives a total of 311,500 cubic feet per second.

As an example of the effectiveness of these lakes as a reservoir, Mr. Reid says:—

> If a rainfall of three inches in the 24 hours were to fall simultaneously over the vast region draining into Lake Superior, it would only have the effect of raising the lake nine inches. In that case, it would take 90 days to run off into Lake Huron, which, with Lake Michigan, would take as long to run off into Lake Erie; so that it would take six months for the full effects of a flood in Lake Superior to be spent at Niagara Falls. The total fall in the river from Lake Erie to Lake Ontario is 329 feet, divided as follows:—Lake Erie to the rapids above the Falls, 15 feet; in the rapids, 55 feet: at the Falls, 161 feet; and from the Falls to Lake Ontario, 98 feet. The total power in the Falls, from the head of the upper rapids to the whirlpool rapids, according to the above estimate as to volume of water, is 9,400,000 h. p., or about 7,000,000 h. p., after allowing for loss of efficiency in the turbines. This is with a fall of 276 feet.

The actual fall which will be used by the Cataract Construc-



Transverse Section

---

[1] Abstract of a paper read before the Society of Arts.

tion Company is only half of this, or 140 feet, and consequently the power which they would be capable of developing, if they utilized the whole of the Falls, would be about 3,500,000 horse power effective.

There are two falls at Niagara—one called the Horseshoe Fall and the other the American Fall. The former has a length of 812 yards, and the latter of 325 yards, but about $\frac{9}{10}$ths of the water passes over the Horseshoe Falls, and only about $\frac{1}{10}$th over the American Falls. It might be supposed then, that when 100,000 or 200,000 h. p. are taken from the American side of the river for conversion into power, there would be a material diminution in the volume passing over the American Falls; but from a special investigation made by Mr. Bogart, it appears pretty certain that the deficiency of water will be made up by the water from the other side of the river, before the latter has been divided between the two falls by Goat Island.

The idea of utilizing the Falls of Niagara is a very old one, but it is only of late years that the application of electricity has been sufficiently developed to make the problem of distributing the power capable of being worked out on a paying financial basis. The power of the Falls, has, however, been utilized to a certain limited extent for many years past. A canal has been cut from the river above the falls on the American side, skirting the side of Niagara Falls city, and ending at the cliffs about half a mile below the American Falls. At this point a few acres of land are given up to mills where turbines are placed, and the water is discharged from the face of the cliff after having utilized only a very small proportion of the fall available. When the Cataract Construction Company undertook to further develop the wasted power, an extension of this plan of using a canal was open to many objections. There was a difficulty in getting rights of way, and there was also a difficulty in getting a suitable tract of land on the face of the cliffs for developing a manufacturing city. Moreover, by having the manufacturing city which is to be developed a mile or two above the Falls, it would not interfere in the same way with the natural beauties of the place. It was consequently resolved to develop the new method which has now been carried out. About a mile and a half above the American Fall a canal has been dug out 500 feet wide, and 1,500 feet long, with a depth of 12 feet. Along the edge of this canal, wheel pits are being dug 160 feet deep, at the bottom of which turbines will be placed. The water is admitted to the penstocks by lateral passages or head-races which can be closed by gates. After the water has exerted its power upon the turbines, it flows into a tunnel, with a grade of seven feet per 1,000, which carries it away a distance of 6,700 feet, under the city of Niagara Falls, and the water is discharged in the chasm below the Falls, just below the suspension bridge.

The most important piece of work was the cutting of the tunnel. The rocks through which this passes consist of limestone and shale. It was hoped at first, that, by driving the tunnel altogether through the limestone, no lining would be necessary. Specimens of the limestone were forwarded to experts, and from the reports of these gentlemen, there seemed little doubt that these expectations would be realized. But at the very commencement of the work it became apparent that the character of the rock was such that exposure to the air deteriorated it, and it was not possible to proceed without lining the tunnel. This involved considerable extra expense, but it enabled us to bring out the mouth of the tunnel at a lower level—that is to say, in the shale. The extra cost of lining this tunnel with four courses of bricks was very considerable, but it is to be hoped that by so doing, a permanent structure has been provided which will not give trouble in the future. At the mouth of the tunnel, a lining is provided on the invert and sides made of cast-iron plates. The rock excavation had an average height of 26 feet, and was effected on three different benches. The top bench, nine feet high, to the top arch has always extended ahead of the second bench, eight feet high. When these were completed, the bottom bench was commenced. The tunnel is shaped something like a horseshoe. It may be taken as being 19 feet wide by 21 feet high inside the brickwork, and has a cross sectional area of 386 square feet over its entire length. Three shafts were used in construction, one on the face of the cliff at the mouth of the tunnel; another called Shaft No. 1, 2,650 feet from the mouth, with a depth of 206 feet, and a section 10 feet by 20; while shaft No. 2, at 5,200 feet from the mouth, is the same size, and is 196 feet deep.

The rough arch cut in the rock was lined with timber. Then four courses of brick were built inside to form the arch, and the space between the timber and brick was filled at the top with rubble, and at the lower parts of the arch with rubble and cement.

The engineering work of importance, next to the development, was the cutting of the canal. It was found necessary to line this canal with solid masonry. Apertures are left, at definite points, to admit water for the head-races into the penstocks for the turbines. In order to dig out this canal it was necessary to make a cofferdam at its outlet, to prevent the works from being flooded by the river. This cofferdam forms only a part of a system of cofferdams, which already extend along a considerable distance on the face of the river. These cofferdams form the boundary of a large tract of land which has been reclaimed from the river. The material used in their construction, and in filling up the reclaimed space, was made of the material taken out of the tunnel. In this manner 30 acres of reclaimed land have been reserved for the Niagara Falls Paper Company, who have already constructed enormous factories for the manufacture of paper from wood pulp. This company utilizes the water power direct, and leases from the Cataract Construction Company the right to use the tunnel as a tail-race. It has sunk its own wheel pit, and is putting in its own turbines, to the extent of 6,000 h. p.

The Cataract Construction Company has already sunk a shaft sufficient to accomodate three of the 5,000 h. p. turbines which are to be used for the work of distributing light and power. Considerable difficulty was met with in sinking this shaft, by the influx of water through a seam at a depth of about 30 feet below the surface. These difficulties have never interfered with the progress of the work, which has now been successfully carried out. The turbines which are to be used are of 5,000 h. p., revolving at 250 revolutions per minute, of the Girard or impulse type, with a regulator for adjusting the flow of water. Each turbine is double. Attached to the shafts of the turbines are vertical shafts, extending to the surface of the ground, and, on the top of these shafts, the dynamos are to be mounted, which will transmit electricity, for light and power purposes, to the surrounding districts and to Buffalo. The turbines are from the designs of Messrs. Faesch and Piccard, of Geneva, who transmitted the working drawings to America; and the contract for these turbines has now been given out to the I. P. Morris Company, of Philadelphia, two turbines having been ordered in the first instance. Twenty of these will be required to utilize the full capacity of the tunnel, which is 100,000 h. p. (See diagram on page 64.)

ALTERNATE CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY.—II.

BY NIKOLA TESLA.

In operating an induction coil with these rapidly alternating currents, it is astonishing to note, for the first time, the great importance of the relation of capacity, self-induction, and frequency as regards the general result. The combination of these elements produces many curious effects. For instance, two metal plates are connected to the terminals and set at a small distance, so that an arc is formed between them. This arc *prevents* a strong current to flow through the coil. If the arc be interrupted by the interposition of a glass plate, the capacity of the condenser obtained counteracts the self-induction, and a stronger current is made to pass. The effects of capacity are the most striking, for in these experiments, since the self-induction, and frequency both are high, the critical capacity is very small, and need be but slightly varied to produce a very considerable change. The experimenter brings his body in contact with the terminals of the secondary of the coil, or attaches to one or both terminals insulated bodies of very small bulk, such as exhausted bulbs, and he produces a considerable rise or fall of potential on the secondary, and greatly affects the flow of the current through the primary coil.

In many of the phenomena observed, the presence of the air, or, generally speaking, of a medium of a gaseous nature (using this term not to imply specific properties, but as contradistinction to homogeneity or perfect continuity) plays an important part, as it allows energy to be dissipated by molecular impact or bombardment. The action is thus explained :—

When an insulated body connected to a terminal of the coil is suddenly charged to a high potential, it acts inductively upon the surrounding air, or whatever gaseous medium there might be. The molecules or atoms which are near it are, of course, more attracted, and move through a greater distance than the further ones. When the nearest molecules strike the body they are repelled, and collisions occur at all distances within the inductive distances. It is now clear that, if the potential be steady, but little loss of energy can be caused in this way, for the molecules which are nearest to the body having had an additional charge imparted to them by contact, and not attracted until they have parted, if not with all, at least with most of the additional charge, which can be accomplished only after a great many collisions. This is inferred from the fact that with a steady potential there is but little loss in dry air. When the potential, instead of being steady, is alternating, the conditions are entirely different. In this case a rhythmical bombardment occurs, no matter whether the molecules after coming in contact with the body lose the imparted charge or not, and, what is more, if the charge is not lost, the impacts are only the more violent. Still, if the frequency of the impulses be very small, the loss caused by the impacts and collisions would not be serious unless the potential were excessive. But when extremely high frequencies and more or less high potentials are used, the loss may be very great. The total energy lost per unit of time is proportionate to the product of the number of impacts per second, or the frequency and the energy lost in each impact. But the energy of an impact must be proportionate to the square of the electric density of the body, on the assumption that the charge imparted to the molecule is proportionate to that density. It is concluded from this that the total energy lost must be proportionate to the product of the frequency and the square of the electric density; but this law needs experimental confirmation. Assuming the preceding considerations to be true, then, by rapidly alternating the potential of a body immersed in an insulating gaseous medium, any amount of energy may be dissipated into space. Most of that energy, then, is not dissipated in the form of long ether waves, propagated to considerable distance, as is thought most generally, but is consumed in impact and collisional losses—that is, heat vibrations—on the surface and in the vicinity of the body. To reduce the dissipation it is necessary to work with a small electric density—the smaller the higher the frequency.

The behavior of a gaseous medium under such rapid alternations of potential makes it appear plausible that electrostatic disturbances of the earth, produced by cosmic events, may have great influence upon the meteorological conditions. When such disturbances occur, both the frequency of the vibrations of the charge and the potential are in all probability excessive, and the energy converted into heat may be considerable. Since the density must be unevenly distributed, either in consequence of the irregularity of the earth's surface, or on account of the condition of the atmosphere in various places, the effect produced would accordingly vary from place to place. Considerable variations in the temperature and pressure of the atmosphere may in this manner be caused at any point of the surface of the earth. The variations may be gradual or very sudden, according to the nature of the original disturbance, and may produce rain and storms, or locally modify the weather in any way.

From many experiences gathered in the course of these investigations it appears certain that in lightning discharges the air is an element of importance. For instance, during a storm a stream may form on a nail or pointed projection of a building. If lightning strikes somewhere in the neighborhood, the harmless static discharge may, in consequence of the oscillations set up, assume the character of a high frequency streamer, and the nail or projection may be brought to a high temperature by the violent impact of the air molecules. Thus, it is thought, a building may be set on fire without the lightning striking it. In like manner small metallic objects may be fused and volatilized—as frequently occurs in lightning discharges—merely because they are surrounded by air. Were they immersed in a practically continuous medium, such as oil, they would probably be safe, as the energy would have to spend itself elsewhere.

An instructive experiment having a bearing on this subject is the following:—A glass tube of an inch or so in diameter and several inches long is taken, and a platinum wire sealed into it, the wire running through the centre of the tube from end to end. The tube is exhausted to a moderate degree. If a steady current is passed through the wire it is heated uniformly in all parts and the gas in the tube is of no consequence. But if high frequency discharges are directed through the wire, it is heated more on the ends than in the middle portion, and if the frequency, or rate of charge, is high enough, the wire might as well be cut in the middle as not, for most of the heating on the ends is due to the rarefied gas. Here the gas might only act as a conductor of no impedance, diverting the current from the wire as the impedance of the latter is enormously increased, and merely heating the ends of the wire by reason of their resistance to the passage of the discharge. But it is not at all necessary that the gas in the tube should be conducting; it might be at an extremely low pressure, still the ends of the wire would be heated; as, however, is ascertained by experience, only the two ends would in such case not be electrically connected through the gaseous medium. Now what with these frequencies and potentials occurs in an exhausted tube, occurs in the lightning discharge at ordinary pressure.

From the facility with which any amount of energy may be carried off through a gas, it is concluded that the best way to render harmless a lightning discharge is to afford it in some way a passage through a volume of gas.

The recognition of some of the above facts has a bearing upon far-reaching scientific investigations in which extremely high frequencies and potentials are used. In such cases the air is an important factor to be considered. So, for instance, if two wires are attached to the terminals of the coil, and streamers issue from them, there is dissipation of energy in the form of heat and light, and the wires behave like a condenser of larger capacity. If the wires be immersed in oil, the dissipation of energy is prevented, or at least reduced, and the apparent capacity is diminished. The action of the air would seem to make it very difficult to tell, from the measured or computed capacity of a condenser in which the air is acted upon, its actual capacity or vibration period, especially if the condenser is of very small surface and is charged to a very high potential. As many important results are dependent upon the correctness of the estimation of the vibration period, this subject demands the most careful scrutiny of other investigators.

In Leyden jars the loss due to the presence of air is comparatively small, principally on account of the great surface of the coatings and the small external action, but if there are streamers on the top, the loss may be considerable, and the period of vibration is affected. In a resonator, the density is small, but the frequency is extreme, and may introduce a considerable error. It appears certain, at any rate, that the periods of vibration of a charged body in a gaseous and in a continuous medium, such as oil, are different, on account of the action of the former, as explained.

Another fact recognized, which is of some consequence, is, that in similar investigations the general considerations of static screening are not applicable when a gaseous medium is present. This is evident from the following experiment: A short and wide glass tube is taken and covered with a substantial coating of bronze, barely allowing the light to shine a little through. The tube is highly exhausted and suspended on a metallic clasp from the end of a wire. When the wire is connected with one of the terminals of the coil, the gas inside of the tube is lighted in spite of the metal coating. Here the metal evidently does not screen the gas inside as it ought to, even if it be very thin and poorly conducting. Yet, in a condition of rest, the metal coating, however thin, screens the inside perfectly.

PROVISIONAL PROGRAMME FOR THE INTERNATIONAL ELECTRICAL CONGRESS OF 1893.

THE General Congress Committee of the American Institute of Electrical Engineers has just received the report of its sub-committee, embodying a provisional programme for the conduct and work of the Congress, to be held in Chicago during this year.

The sub-committee consisting of Mr. Carl Hering, chairman; Prof. Wm. A. Anthony and Mr. A. E. Kennelly, made the following recommendations, in the course of an admirable report:—

RECOMMENDATIONS.

(1.) *Ratification of the adoption of units, terms and definitions made by previous International Electrical Congresses.*

(2.) *Defining and adopting practical units for measuring and designating the measurements of the following quantities: Magneto-motive force; magnetic flux; magnetic intensity; magnetic reluctance; electric conductivity; illumination.*

Your Committee recommends the following:

The value of the practical unit of magneto-motive force to be one-tenth of the absolute unit, that is, equal to $\frac{1}{4\pi}$ ampere turn.

The value of the practical unit of magnetic flux to be 10^8 absolute units or lines.

The value of the practical unit of magnetic intensity to be 10^8 absolute units, that is, 10^8 lines per square centimetre.

The value of the practical unit of reluctance to be 10^{-9} absolute units.

The value of the practical unit of electrical conductivity to be 10^{-9} absolute units, that is, to the reciprocal of the ohm. This makes it equal to the unit proposed some time ago and known to some extent by the name of "mho." It should be given this value in order that it correspond with the already adopted unit.

The value of the practical unit of illumination to be a violle at the distance of one metre. The violle is the unit of light or candle power already established; by making the distance a metre the practical unit will be approximately equal to the carcel-metre, the the foot-candle or to 10 metre-candles or metre-kerzen, all three of which units are already in use to some extent.

It has been announced that a proposition will be made at this Congress to change the values of some of the practical units which have been adopted by previous Congresses and are already in universal use. Among these are the ampere and the farad. It is urgently recommended by the Committee that such changes should not be favored, since they would necessarily be followed by great confusion and would of necessity have to be accompanied by some change in these well established names in order to distinguish these new units from those now existing.

(3.) *Adopting names for the following practical units: Magneto-motive force; magnetic flux; magnetic intensity; magnetic reluctance; inductance; electrical conductivity; illumination.*

The following names are suggested for these units:

For the practical unit of magneto-motive force, the name "gilbert."

For the practical unit for magnetic flux, the name "weber." This term was formerly applied to a unit of current, but its use in this sense was so limited, and it has been abandoned for so long a time that no confusion would be likely to arise.

For the practical unit of magnetic intensity, the name "gauss." This name has already come into use to such an extent that objections to it will not be likely to arise.

For the practical unit of magnetic reluctance, the name "oersted."

For the practical unit of inductance, the name "henry." This name has already come into use quite extensively and it would therefore be very undesirable to change it. The value of this unit has already been fixed as equal to 10^9 absolute units or nearly to the length of an earth's quadrant.

For the practical unit of electrical conductivity, equal to the reciprocal of the ohm, the name "mho." This name has been in use for some time and is already well known. It is thought better to recommend it rather than to select and introduce a new name.

For the practical unit of illumination, the name "lux." This name has been in use for some time past for the foot-candle. If the unit violle-metre is adopted, the name "lux" could be given to it without materially changing the meaning, as the violle-metre is approximately equal to the foot-candle. One of the compound terms "foot-candle," "metre-candle" or "metre-carcel" might perhaps be preferable to "lux" as they explain themselves.

It has been suggested to name the units "kilowatt-hour" and "ampere-hour." The committee, however, recommends that inasmuch as these terms explain themselves, and are not longer than some others in use, to give them special names would burden a system of nomenclature unnecessarily.

(4.) *Defining and adopting modes of embodying the following principal units of measurement in concrete standards capable of being readily reproduced, and adopting names for them or for the theoretical units by which they can be distinguished from each other:—Ampere, ohm, volt, watt, standard candle.*

The following definitions of these units are recommended:

An ampere shall be that unvarying current, which, when passed through a solution of nitrate of silver in water, in accordance with the specifications recommended in the recent report to the British Board of Trade, deposits silver at the rate of 0.001118 of a gramme per second.

An ohm shall be the resistance offered by a column of mercury at the temperature of melting ice 14.4521 grammes in mass, of a constant cross-sectional area and of a length of 106.3 centimetres.

A volt shall be the product of this ampere and this ohm.

A watt shall be the product of the square of this ampere and this ohm.

The other units such as the coulomb, the farad, and the joule, shall be taken as derivatives in terms of this ampere and this ohm.

In order to create as little confusion as possible by the introduction of this set of units which are to become the universal standards, and in order to distinguish them readily from the true, theoretical or abstract units defined in terms of the absolute units, it is recommended to call the former simply "amperes," "ohms," "volts," etc., or more specifically "standard amperes," "standard ohms," etc., and to call the theoretical units "true amperes," "true ohms," etc. The latter term has already come into use in this sense.

The unit of resistance known as the B. A. unit, shall be taken as equal to 0.9866 of this ohm.

The E. M. F. of a Clark cell at 15° C., prepared in accordance with the specification recommended in the recent report to the British Board of Trade shall be taken as not different from 1.434 of these volts by more than one part in 1,000. The co-efficient of temperature shall be taken as.....................

The standard candle shall be taken as equal to the light from a lamp like the one that is known as the Hefner-Alteneck standard amyl acetate lamp, which is to be defined by its dimensions and the height of the flame, the dimensions being such that the light shall be equal to the "bougie-decimale," the practical unit adopted at the Paris Congress of 1889.

It has been suggested also that a universal wire gauge be defined and adopted, but the committee recommends that no action be taken by this Congress in this matter, as it is not likely that any one scale would ever be universally adopted by manufacturers, even if defined and adopted by a Congress. The universal introduction of the metric system and the designation of wires by their diameters in millimetres, is thought to be the only satisfactory solution of this question for international work.

(5). *Adopting an international system of notation and conventional symbols, for designating different quantities.*

The system suggested to the last Congress by Mr. E. Hospitalier, of Paris, is recommended by your committee, although doubtless some changes will be found desirable.

(6). *Defining the following terms:—Impressed* E. M. F.*: inductivity; inductance; reluctivity; Matthiessen's standard; north and south pole.*

The following definitions are suggested:

The impressed E. M. F. is the ratio of the total activity in an electrically conducting circuit to its instantaneous current-strength.

The inductivity at any point in an isotropic medium is the ratio, added to unity, of four π times the intensity of magnetization there existing, to the magnetizing flux-density. Inductivity is synonymous with "permeability." The electromagnetic dimensional formula is $L^0\ M^0\ T^0$; the conventional symbol is μ.

Inductance.—(*a*) Self-inductance is the ratio of the total magnetic induction linked with and established by an electric current, to the uniform strength of the same. The inductance of a conducting circuit is constant when its environing medium has constant inductivity. (*b*) The mutual inductance of one electric circuit upon another is the ratio of the total magnetic induction linked with the second, due to a uniform current in the first, to the strength of that current. The mutual inductance between two electric circuits is reciprocally equal when the environing medium has constant inductivity. The electromagnetic dimensional formula is $L^1\ M^0\ T^0$. The absolute unit is one centimetre; the practical unit, one henry.

The reluctivity of a medium at any point is the volume differential of the reluctance thereat. Simple definition: Reluctivity is the reluctance per unit volume. The electromagnetic dimensional formula is $L^0\ M^0\ T^0$. The absolute unit is one C. G. S. unit of reluctance per cubic centimetre; the proposed practical unit is one oersted per cubic centimetre.

The resistance of copper known as Matthiessen's standard shall be defined as follows:—The resistance of a soft copper wire one metre long, weighing one gramme, is 0.14365 B. A. units at 0° C. This definition is the one recommended by the Committee of the American Institute of Electrical Engineers on Matthiessen's Standard. The reasons for selecting this one are given in that report.

The north pole of a magnet shall be defined as being that one which seeks the geographic north pole, and the south pole that one which seeks the geographic south pole. This is the generally accepted definition, but it is thought desirable to formally define it.

(7.) *Defining and adopting expressions:—For alternating currents of more than one phase; for describing phenomena of alternating currents and of electromagnetic waves.*

It is recommended to adopt the following expressions: "simple" alternating current for the usual alternating currents in which there is but a single phase; "di-phase" alternating currents for two alternating currents whose phases differ in time by 90 or 270 deg.; "tri-phase" alternating currents for three alternating currents whose phases differ in time by 60 or 120 deg.; "poly-phase" alternating currents for such as have more than three phases.

For expressions for describing phenomena of alternating currents and electromagnetic waves, the committee solicits suggestions.

(8.) *Recommending the more universal use:*

Of the term "voltage" as synonymous with "difference of electrical potential" or P. D. *in place of the terms "potential," "tension" or "pressure," the use of which in this sense it is recommended to abandon.*

Of the term "transformer" instead of "converter;"

Of the term "dynamotor" for a continuous current transformer;

Of the term "continuous current" instead of "direct current;"

Of the unit of power "kilowatt" instead of "horse-power;"

Of the metric system of weights and measures and suggesting means by which its introduction will be facilitated.

Regarding the programme for carrying out this work in the most satisfactory manner to all parties, and with the least loss of time, the Committee recommends that an International Congress is the place to close, but not to open a discussion on questions about which international agreement is to be had; it is therefore urgently recommended that action be taken at once to open the discussion of such matters now, in order that expressions of opinions, and, if possible, agreements may be arrived at prior to the meeting of the Congress. To this end the committee recommends that the suggestions embodied in this report, or as many of them as you may see fit to designate, be printed and sent to all the leading electrical and physical societies and journals in this country and abroad, with a request that they aid this work by making them public, by freely discussing them, and by sending copies of such discussions and any further suggestions to the General Congress Committee of this Institute, care of the Secretary, 12 West Thirty-first street, New York City. That a sub-committee of the Institute prepare from time to time a classified summary of such discussions to be sent to the leading electrical and physical journals for publication here and abroad, and that it present a final summary of this international discussion at the Congress. This discussion ought to be closed by July 1, 1893.

It is recommended also that the Institute invite other societies to coöperate with it by appointing special committees to discuss and report to their respective societies on these international questions and to publish their conclusions in the electrical journals of their country.

It has been suggested that various committees be appointed to prepare reports on the international questions on which agreement is desired, and to submit these at the meeting of the Congress. The committee, however, believes that to postpone the discussion until the Congress is in session, would lead to no satisfactory results, as was shown at the last Congress of 1891, in Frankfort. It therefore urges that the discussion take place through the medium of the journals *prior* to the meeting of the Congress, and that the only report submitted to the Congress be a summary of such discussions.

Meetings.—Regarding the meetings of the Congress, the committee recommends that, as in the Paris Congress of 1889, the meetings be divided into (a) *General Meetings*, one at the opening and one at the closing of the Congress, which are to be devoted to the consideration of general questions and those on which agreements are desired, and to the reading of papers of a general character; (b) *Sectional Meetings* for the reading of all other papers. The following division into sections is recommended:

1. Electro physics, units, measurements, and all electrical matter of a purely scientific nature; 2. Dynamos, motors, transformers, etc.; 3. Systems, central stations, installations, lamps, etc.; 4. Electric telegraphy, telephony and signaling; 5. Electric railways; 6. Electro-chemistry, batteries, electro-metallurgy; 7. Electro-physiology, and electro-therapeutics; 8. Legal questions.

Papers.—It is suggested that specific invitations be extended by the Congress Auxiliary to prominent electrical engineers and physicists to prepare papers on specified subjects to be read and discussed at the Congress Meetings. Also, that a general invitation be extended for other papers, which are to be submitted not later than July 15, 1893, to a committee on papers appointed by the Chairman of the Congress Auxiliary; that this committee shall examine and accept or return the latter, and at its discretion shall print any or all of those accepted as well as those solicited, in form for circulation at least one week prior to the meeting at which they are to be read; that the papers shall be read in full, in abstract or by title, as that committee shall direct.

The following subjects of papers are offered as a suggestion to the Congress Auxiliary merely as a basis and not as a complete list. (Suggestions also of English Committee.)

The criterion of sensitiveness of galvanometers; or on the theory of their construction.

The working of National or Municipal Laboratories for testing meters and instruments.

The practical results and economy of the employment of accumulators in Central Station systems of supply.

On the relation between weight of copper and iron in dynamos and their output.

Nomenclature and notation of magnetic circuit—or on Standards and Units of Magnetism.

On the economic use of transformers under various conditions of supply.
Electricity meters from an European standpoint.
Electricity meters from a British standpoint.
Electricity meters from an American standpoint.
Choice of materials for standards of electrical resistance.
Nomenclature of phenomena of electromagnetic waves.
Standards for electrical measurement.
Alternating current transformers from an American standpoint.
High frequency and high potential phenomena.
Dynamo construction.

The Committee suggests that papers should be solicited by the General Congress Committee of this Institute on the work of the early electricans of this and foreign countries considered from a modern standpoint, and their importance in the development of the science of electricity, including descriptions and illustrations of models and apparatus used.

Membership.—It is suggested that the membership of the Congress be divided into delegated members and members; that the dues for each shall be $5 (five dollars); that only delegated members and members be admitted to the meetings, and be permitted to take part in the discussions; that any one shall be entitled to become a member; that delegated members shall be appointed by governments, physical and electrical societies, and shall be approved by an international committee whose decision shall be final; that questions on which international agreement is desired be decided by the delegated members, whose decisions shall be submited to the whole Congress for approval or rejection in part or in whole, but not for alteration. It is recommended that the United States Government be requested to extend a formal invitation to foreign governments and societies to send delegates to this Congress.

The General Committee by resolution adopted on Dec. 28, 1892, gives a list of subjects extending over a wide range of electrical work and upon which papers are invited, to be presented at the Congress.

A FRANCO-AUSTRALIAN PACIFIC CABLE.

As the outcome of negotiations between the French government and that of Queensland, Australia, the first link of the long talked of submarine cable, to complete the chain of telegraphic communication about the earth, is finally to be laid from the latter colony to New Caledonia.

The Queensland and New South Wales governments each guarantee the French Cable Co. $10,000 per year for 30 years, provided the French government will guarantee $40,000 for the same period, the company agreeing to lay, maintain and work the line, and sending government messages free of charge up to the extent of the guarantee. The working expenses are not to exceed $12,000 and receipts over that amount will go toward reducing the guarantee.

The Société Française des Telegraphes Sous-Marins ready to lay the succeeding links as quickly as possible, and the second section, from New Caledonia to the Fiji Islands, at once. The proposed route of the complete cable is from Queensland to New Caledonia, to Fiji, to Samoa, to the Fanning Islands, to Honolulu and thence to either San Francisco or Vancouver.

A PRACTICAL TALK ON THE INSTALLATION OF ISOLATED ELECTRIC LIGHTING PLANTS.

At the meeting of the New York Electrical Society held on Wednesday, Jan. 11, at Columbia College, Mr. Augustus Noll, general superintendent of the New York Electrical Equipment Company, delivered a most interesting discourse on the above subject.

In laying out such plants Mr. Noll considered that the first point to be determined was the size of power units to be employed. His experience had taught him that it was more desirable, where more than one machine is employed, to make the units of different sizes. Thus, if two machines were to be employed it would be found more economical to employ one machine having 40 per cent. and another 60 per cent. of the total capacity of the plant. With such an arrangement the smaller machine could economically handle the lighter load, and the full load could also be handled with high economy.

The size of the units being determined, the question of wiring next presented itself. In this department of the work Mr. Noll showed that considerable ingenuity could be exercised in selecting methods of distribution. He showed by diagrams various methods of determining central points for distribution and illustrated the various systems of wiring by the feeder system, the feeder and main to central points and the crib system. He also showed a number of methods of wiring special installation, such as depots, hotels, etc. Wherever it was possible he deemed it advantageous to run wires in recesses, as they could then, if necessary, be more easily got at and with less inconvenience to the occupants of buildings, than where they were run in the side walls. In breweries Mr. Noll deemed it advisable not to run the wires in moldings nor in tubes, and, in general, to have as few points of contact or support for the wires as possible. This was best carried out by suspending the conductors from porcelain knobs.

Mr. Noll then took up the subject of theatre lighting. The rules of the Fire Department in this city require that all switches, cut-outs, etc., that control the parts of the building accessible to the public, should be kept in a room close to the main entrance and always accessible.

In the modern theatre there are two systems of illumination. The first, the general illumination of the house, and second, the stage lighting proper. The general lighting is effected by means of lamps around the balconies, around the pillars, and near the ceiling; these lights are usually thrown off entirely when the curtain rises, and none of them as a rule can be dimmed, though each circuit can be separately controlled. The stage lighting, on the other hand, is under full control and must necessarily be so.

Mr. Noll then showed the special adaptability of the crib system of wiring to large factories in which the location of the lights is frequently changed, and which if not previously provided for in the wiring, may lead to very poor results in both the life and illuminating power of the lamps.

The lecturer laid great stress on the value of interior conduits when properly employed. They not only insured against the carelessness of plasterers, who had spoiled much good work in the past when wires were merely laid against the bare side walls, but they also excluded moisture and permitted of easy location of any trouble and of testing out. Mr. Noll did not advocate the use of the crimping tool in making joints in the tubes. In his practice he strips the brass armor off the tube back for about ⅜ of an inch, and applies to the bared end an insulating compound. When the sleeve is slipped on the entire joint is first covered with rubber tape and then with the regular linen tape. The results obtained by means of this joint were highly satisfactory.

In the discussion which followed, Prof. F. B. Crocker remarked that he agreed with Mr. Noll in the wisdom of employing units of unequal size in isolated plants, and he had advocated this method in the past.

Mr. C. O. Mailloux, speaking on the same subject, drew attention to the fact that there ought to be considered here, that objections might be, and had been, raised by the engineers in charge of plants to the multiplication of apparatus of different sizes. In a recent case coming under his notice, the objections of the engineer to the installation of units of different sizes were so strong that they could not be overcome. Mr. Mailloux while considering conduits excellent for branches, doubted whether they thoroughly fulfilled their mission when employed for feeders and mains. He considered molding better adapted for this purpose on account of the difficulty of drawing heavy wires through the conduits.

LITERATURE.

De Magnete. By William Gilbert, M. D. Translated by P. F. Mottelay; New York. *John Wiley & Sons*, li + 380 pp. 6 × 9 inches. Price, $4.00.

THE lively discussion which has been going on for the past few weeks relative to the forthcoming publication of a translation of Gilbert's "De Magnete," and of which note was made in our last issue, has drawn considerable attention to a work which, though well known to the student and amateur of early electrical literature, has nevertheless been merely a subject of curiosity and awe to the ordinary electrical reader. While the appearance of the promised translation undertaken by the Gilbert Club some years ago is still a thing of the future, we have before us the advance proofs of a translation undertaken by Mr. P. F. Mottelay, which have been kindly placed at our disposal by the publishers.

Wm. Gilbert, M. D., E. E.

To the reader in general Gilbert's great and immortal fame rests on the fact that he first subjected the magnet to rigid and systematic investigation, and deduced the fact, by masterly logic, that the earth itself was a great magnet; and again that he clearly discerned the difference between electrics and non-electrics, and showed that the nature of the attraction exerted by the electrified body was of quite a different nature from that which endowed the magnet with its power.

But these general statements which are to be found in many text-books, give the reader no idea of the many exhaustive and indeed brilliant experiments which Gilbert undertook to verify his arguments. We say brilliant, advisedly, for, considering the state of knowledge,—or rather of ignorance, and worse than ignorance,—misinformation,—at the time, Gilbert's work is indeed a monument to human intelligence.

At the very outset Gilbert lays down his method of attacking the problem taking as an example the study of geometry in which "from certain, slight and readily understood foundations" we rise "to the highest and most difficult demonstrations, whereby the ingenious mind ascends above the ether." He inveighs with vehemence against the literature on the subject which had appeared up to his time, in which so called philosophers, physicians, mathematicians and astrologers instead of seeking to verify their opinions by experiments, merely repeat the vagaries of previous writers.

Gilbert's first book goes into the details of these ancient writers, in which we find not a few curious myths with respect to the magnet. Thus among others, that when the lodestone is rubbed with garlic it does not attract iron, nor when it is in the presence of a diamond.

He then takes up the subject of the lodestone and of its general nature, and with suitable arguments concludes to use the lodestone in the form of a sphere representing the earth, also a globe. With this magnetic globe or "terrella," Gilbert, by employing a "versorum," as he calls it, that is, a small pivoted magnetic needle, shows how the inclination of the needle varies from equator to pole and changes in the same manner as that shown by a suspended needle at different latitudes of the earth's surface.

He next studies the polarity of the lodestone, for which purpose he places it in a boat and floats it in a vessel of water. This leads him to the investigation of the magnetic properties of iron itself, and he shows how wrought iron not magnetized by the lodestone attracts iron, due to the magnetism induced in it by the earth. In these experiments besides employing short magnets floated on water by being passed through pieces of cork, Gilbert also employs a rod of iron six feet in length and more than ⅛ inch in diameter, suspended by a fine strong silk thread, "twisted differently and not all in one direction." He also proves that magnetic properties exist, though weaker, both in smelted iron and in iron ore.

It is curious to note here that Gilbert distinctly recognized the nature of polarity in a magnetic body, and indeed was the first to use the term "pole." Although evidently having a comprehension of the outward effects of polarity, he does not seem to have grasped the idea of a certain molecular arrangement which modern theory assigns as the cause of polarity in magnets. Indeed, seeking to explain the cause of the attractive power of electrical bodies, he still clings to the older idea of "effluvium" and "humors." Nevertheless he shows conclusively that the attraction which excited amber exerts is quite different from that of the magnet, and it is most interesting to follow him through the upsetting of various ancient theories by the simple expedient of an actual experiment, and thus forever sustaining or overthrowing theories which had been current theretofore. To show the acute perception of the principles possessed by Gilbert we cannot help citing here two experiments. Thus he says that "moisture from steam, breath from the mouth, water thrown on the amber instantly checks the effluvium." In contradistinction to this he points out that amber "plainly attracts the body itself, in the case of a spherical drop of water *standing on a dry surface*," being drawn up into a cone.

Gilbert then enters into a discussion of the varying strength of magnets as depending upon the point at which the attracted body is placed and referring especially to the earth and the "terrella," and showing that at the poles the force is strongest. In his numerous experiments he also shows that iron when heated to a red heat loses its magnetic properties, and acquires them again, though feebly, when cool, thus demonstrating for the first time the fact upon which the modern thermo-magnetic motor is based.

The translator has evidently done his work with the greatest care. Many foot notes give the reader the results of the researches of others and throw light on many points not elaborated upon by Gilbert. The work itself is preceded by an excellent biographical memoir of Gilbert, and by the eulogistic address of Edw. Wright, Gilbert's contemporary. We reproduce here, in small facsimile the ornamentation of the title page; and the portrait of Gilbert that is to accompany the translation.

The work contains a fac-simile reproduction of all the diagrams appearing in the original, and also of the title page upon which is what is said to be the autograph signature of the author.

It would take us too far to enter into the many interesting experiments undertaken by Gilbert in support of his arguments. But enough has been said to show that we have here a work well worth the attention of all interested not only in the early history of electricity but in any of its present applications.

Original Papers on Dynamo Machinery and Allied Subjects. By John Hopkinson, M. A. D. Sc., F. R. S. New York; *The W. J. Johnston Co., Ltd.*, 1892. 249 pages, 98 illustrations, 5x7 inches. Price $1.00.

The influence of Dr. Hopkinson's work on the construction of dynamo electric machinery has been of a character to warrant the assertion that it drew the designing of dynamo electric machinery from the slough of empiricism up to the firm ground of an exact science. A complete record of his work in this field, therefore, will be welcome to the student as well as to the practical designer.

In the volume before us we find the reprints of nine original papers by Dr. Hopkinson and read before various societies. The first two "On Electric Lighting," (1879) contain the original enunciation of the characteristic curve of the dynamo. But the most important, perhaps, is that on "Dynamo Electric Machinery," presented to the Royal Society in May, 1886. It was in this paper that Dr. Hopkinson first laid down the methods of the predetermination of dynamo electric machines, and in which the magnetic circuit in a dynamo received an analytical treatment similar to that which Ohm gave to the electric circuit. The best methods of the present day are based on this method first employed by Dr. Hopkinson; and hence the importance of thorough familiarity with the original source needs no further pointing out.

Among the other papers we find one on the "Theory of Alternating Currents," one on "Induction Coils or Transformers," and one also on the "Theory of the Alternating Current Dynamo."

To those interested in electric lighthouse illumination, the paper on "The Electric Light Houses of Macquaire and Tino" will prove exceedingly valuable.

Electric Lighting and Power Distribution, Part I. By W. Perren Maycock, M. I. E. E., New York; *McMillan & Co.*, 5x7 inches, 185 pages, paper. Price, 75 cents.

The raison d' être of this work according to the author is, that there was no reliable elementary work which he could recommend to the beginners in his classes at the City and Guilds of London Institute. In this dilemma the author was forced, as it were, to make his own text book, which we are glad to note is above the average of elementary treatises. Throughout, the author has treated the subject as if the student were before him, and in a language both clear and concise, while at the same time rigorously exact.

The present installment contains chapters on elementary conceptions of force, units, etc., after which follow others on current electricity, induction, electrical measurement and the principles of the dynamo. A valuable feature of the work are the questions which are appended to each chapter and which will enable the student to test his knowledge as he goes along.

The illustrations, with the exception of those representing standard apparatus, have been specially prepared for this work and will be found very helpful. We can heartily recommend this work to beginners.

New Dynamo Tenders' Hand-Book. By F. B. Badt. Electrician Publishing Company. Chicago, 1892. 226 pp. Pocket size. Price, $1.00.

This handy little work, though based on "The Dynamo Tenders' Hand Book" by the same author, is practically a new work, and has been elaborated considerably, without, we are glad to say, making it too bulky for ready reference. The author has entered a little more into the description of the general electrical data and theory of dynamos, which can do no harm to those for whom the book is intended. This is followed by a description of the methods of preparing a dynamo for operation, and a short discussion of the diseases of dynamos. The operation of arc and incandescent lamps, etc., is then taken up, and by a number of very good chapters, leads up to station equipment. Line construction, and the calculation of the size of wires, the application of storage-batteries, and the arrangement of power in the dynamo room, are also clearly set forth. A number of appendices give the rules of the various boards of underwriters, and of similar bodies. The little work is very well written, and the diagrams are quite numerous and help to elucidate the text.

Handbook of Electrical Testing. By H. R. Kempe. Fifth edition. New York, *Spon & Chamberlain*, 1892. 5½ x 8½ inches. 576 pp. Price, $7.25.

This work is too well known to require a detailed review at this time. It has indeed been the standard on the subject for many years, and it is all the more subject for congratulation that the author has in the present edition added largely to the original matter, while thoroughly revising it at the same time. To those engaged in electrical testing of whatever nature this work is simply indispensable. If we have a suggestion to make it would be that the author in the next edition embody the methods of determining mutual and self induction which now play so prominent a part in electrical and magnetic work.

AN ELECTRICAL EXHIBITION FOR ITALY IN 1895.

An international Exhibition of Fine Arts and Electricity is proposed to be held in Rome in 1895-96. It is intended to solemnize the 25th anniversary of the annexation of Rome to the Kingdom of Italy. The site chosen for the exhibition is in the vicinity of "Ponte Milveo," about a mile's distance from "Porto del Popolo," in a very attractive position, bordering on the river, and commanding a fine view of the Sabine Hills.

LEGAL NOTES.

INCANDESCENT LAMP LITIGATION IN BOSTON.

Following up its recent successful efforts against the Sawyer-Man, Westinghouse, Perkins and Mather Companies, as well as the proceedings that Mr. F. P. Fish is instituting against the Sunbeam Company in Chicago, the General Electric Company brought suit in Boston on Monday, Jan. 16, before the United States Circuit Court, Judge Colt sitting, against the Beacon Vacuum Pump and Electrical Company, for infringement of its Edison incandescent lamp patent, and asking for an injunction. The defendants were represented by Mr. Witter, who asked for a postponement of 30 days to enable the defendants to complete their work of making a new defence which, he claimed, would put a different complexion on the whole matter. He did not, however, disclose the nature of this new defence.

He was followed by Mr. Seward, for the complainants, who put in a strong plea for an immediate injunction, basing his argument upon the large amount of business these people were doing. Mr. Seward was followed by a Mr. Brandeis, of Boston, for the defence, and who made an argument for the Beacon Company emphasizing the main points in Mr. Witter's speech.

Mr. R. N. Dyer, of Dyer & Seely, New York, responded to Mr. Brandeis, on behalf of the prosecution, making a still stronger statement of the harm that would come to the General Electric Company from delay in granting the injunction because the defendants would be enabled meantime to run their factory at its highest capacity and fill orders.

Mr. Witter again took the floor, and answered several questions from Judge Colt, who showed himself willing to grant a delay provided the defendants were prepared to present a new defence in good faith. Mr. Witter then offered to retire with Judge Colt, and to put him privately in full possession of the entire defence, after which he thought the judge would certainly allow him the thirty days. Judge Colt said he would grant the defendants one week to get ready and to disclose their case publicly—namely, on Monday, Jan. 23.

Mr. Seward then tried very hard for a restraining order which would prevent the defendants from distributing or selling their product. This was refused. He then endeavored to secure an order of the court compelling the defence to supply the prosecution with information as to the nature of the new defence two days before next Monday. This was also refused, and the case therefore rests without further disclosure until the 23d, when, Judge Colt intimated, if the matter is worthy of further attention, ample time will be given to investigate and develop it.

Word reaches us from Chicago that on Saturday, Jan. 14, Mr. Fish secured, against the Sunbeam Company, from the United States Circuit Court, a restraining order which prohibits the sale of their incandescent lamps, but not the manufacture. It was not a regular injunction.

SOCIETY AND CLUB NOTES.

DISSOLUTION OF THE NEW YORK ELECTRIC CLUB.

As is well known, the New York Electric Club has been struggling with a heavy burden of debt and with a general apathy upon the part of its members, many of whom being members of other and larger social clubs have found it more to their interest and pleasure to frequent the places where the cares of the day would be forgotten rather than brought again to mind. In view of the steady tendency on the part of smaller clubs in New York to disintegrate, and of the difficulty in making ends meet, the officers of the club have determined after long and anxious deliberation that the only thing to be done is to dissolve the club. With this object, a petition has been made by a majority of the officers and by several of the largest creditors for the appointment of a receiver, to wind up the club's affairs; and the due legal steps are now being taken to carry out this programme.

RAILWAY ARRANGEMENTS FOR THE NATIONAL ELECTRIC LIGHT CONVENTION.

THE various passenger associations have granted an excursion rate of a fare and a third to delegates attending the Convention of the National Electric Light Association, to be held in St. Louis, February 28, March 1 and 2, 1893. To secure this rate it will be absolutely necessary for persons purchasing tickets to state to the agent from whom the purchase is made that they contemplate attending said meeting, and to procure from said agent a certificate which, immediately upon their arrival in St Louis, should be left in the Secretary's office, addressed to the undersigned, who will see that it is properly viséd and returned to the owner.

Arrangements are now being made for a special train from New York to St. Louis, which will exceed in the way of equipment and appointments anything that has ever been in service between these two points. To bring this matter to a successful issue, it is very important that the number of passengers who wish to avail themselves of this train should be known at the earliest possible moment. Therefore, it is very desirable, and will facilitate transportation matters greatly, if all delegates who contemplate using this train will make application for space at once.

C. O. BAKER, JR.,
Master of Transportation.
National Electric Light Association,
136 Liberty street, New York.

CANADIAN ELECTRICAL ASSOCIATION.

THE second convention will be held in Toronto on Wednesday and Thursday, January 25 and 26. The convention will assemble for its first session on Wednesday at 2.30 p. m. at the School of Practical Science, where the Association has been kindly invited to hold its meetings.

Among other matters of importance that will come before the convention will be the question of the division of the Association into sections representing special branches of industrial electricity. This separation is considered by many of the members to be necessary for the efficient working of the Association and the advancement of the different departments interested.

Many papers on subjects of special interest will be read, among which may be mentioned a paper by Prof. Rosebrugh of the School of Practical Science; papers on "Testing" by Mr. G. Black, of the G. N. W. Telegraph Co., Hamilton; "Free Wiring" by Mr. J. M. Campbell, of the Electric Light & Power Co., Kingston; "Underground Construction" by Mr. W. A. Tower, of the Bell Telephone Co., Toronto; "Steam Plant and Management of Electric Lighting Stations" by Mr. A. E. Edkins, of the Canadian Association of Stationary Engineers.

Besides an entertainment of a social nature, visits will be made by invitation to the stations of the local electric lighting companies and also to the new Exchange of the Bell Telephone Co.

The headquarters of the Association, during the convention, will be at No. 40 York street, at which address members are requested to call on arrival in the city.

PATENT NOTES.

EQUITY IN PATENT CASES.[1]

BY J. C. CLAYTON.

WHETHER or not the United States Courts, sitting in equity in patent cases, will venture to show a larger liberality in prescribing conditions for the granting of injunctions is a grave question. The statutory patent law rests upon the constitutional provision authorizing the granting of privileges to authors and inventors for the purpose of promoting the progress of science and the useful arts; and the Constitution itself was made to promote the general welfare of the people.

When, therefore, the law is so enforced as to maintain a monopoly that is destructive of the promotion of science or art, or that is against the general welfare, there is a violation of the constitutional and fundamental prerequisites. Though the patentee receives an exclusive grant, he remains subject to those constitutional qualifications; he cannot override them, nor can he overthrow the maxim, *Sic utere, non abutere.* No court of equity should sustain a patentee in the non use or the misuse of his invention. His patent is a contract between himself and the government representing the people, and is the result of a public policy primarily created for the welfare of the people.

Few inventors have ever long anticipated others in the same field; although. for his priority, the inventor gets a patent, yet, as a rule, in a few days or a few years, others would have reached the same result. It is, therefore, against natural justice that a right so given by the people should be used for extortion or oppression, or in any way against the general welfare. In a mere race of diligence Jones may secure a patent for a lamp over Smith, who may have been too late by one day. and Smith may have other cognate valuable inventions useless without the privilege of the Jones patent. Both may be great and successful manufacturers of lamps, and through their healthful competition the people may be greatly benefited. But, if Jones be upheld in his determination that Smith shall not on any terms use the Jones patent, then an "odious monopoly" is created, fair competition is destroyed, Smith is ruined and the people are completely at the mercy of Jones, the monopolist.

In such a case it would seem that a court of equity should be able to refues its peremptory injunction if Smith should secure a reasonable license fee to Jones. In other words, in the high court of conscience (the "court of equity") the familiar and highest principles of equity should govern; and the wrong of a harsh injunction should be balanced against the wrong of an infringement, while the court, holding a just balance between the actual parties, should remember that the public is, in no narrow sense, always an interested party in every suit upon a patent. I know that *strictissimi juris*, an exclusive right is granted to the patentee, and that in a suit, on the law side of the court, this legal right, no matter how harsh it may be, must be enforced. But if the patentee elect to enter the court of conscience rather than the court of law, he must abide by its more liberal and merciful conclusions.

Generally, "equity follows the law," but not to enforce the unconscionable or the cruel, nor to uphold unclean or unmerciful hands. Generally, too, when a patent is finally sustained on the merits, an injunction follows, which practically leaves the respondent and his business to be executed by the complainant without mercy or benefit of clergy! My view is, that there must be a new departure in this respect, either by judicial construction or by statute. And although I took no part in the incandescent lamp case, I was not without a hope that the court might find occasion to take the new departure above suggested.

Indeed, to a notable extent, it did depart from the harsher practice of the past, for it granted leave to apply for a dissolution of the injunction in case the complainant refused to supply its lamps to respondent's customers upon reasonable terms. To this extent I think the court made an advance in the line of mercy and liberality which has been herein suggested; perhaps in the next great patent case, where the respondent has his own additional patents and has invested millions in his plant, the court will go the length I have indicated and permit the respondent to continue his manufacture upon reasonable terms fixed by the court, with due regard to the interests of the parties and of the people.

Unless courts of equity more nearly approach such liberality, as they may by force of construction and constitutional law, some arbitrary statute inimical to patents will soon be enacted. Even now several harsh patent bills are pending in Congress. One authorizes the Secretary of the Interior and the Commissioner of Patents to fix the maximum price for the use of a patent, and provides that in case of a higher price being demanded the patent shall be forfeited to the public; another limits the term of a patent to seven years. In the wise and very liberal administration of equity all interested in patents will find their truest protection.

---

[1] New York *Times*, Dec. 25.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 2, 1893.

Accumulators:—

Secondary Battery, C. R. Arnold, Sharon, Hill, Pa., 489,115. Filed May 21, 1892.

A compound electrode consisting of a number of lead plates separated from one another by layers of lead shot.

Storage Battery Electrode, G W. Harris, New York, 489,186. Filed Apr. 14, 1892

Consists of two series of thin conducting sheets, each series united to an independent integral face, in combination with intermediate sheets of absorbent material.

Secondary Battery Electrode, A. M. Michel, Paris, France, 489,315. Filed Aug. 24, 1892.

Employs an amalgam in which the mercury at least equals in quantity the other metal.

Manufacture of Accumulator Plates, A. M. Michel, Paris, France, 489,316. Filed Aug. 24, 1892.

Consists of forming an alloy of lead and some other metal such as zinc, disintegrating the alloy, eliminating the metal alloyed with the lead, and leaving the latter in a porous condition, and finally compressing it into the desired forms.

Alarms and Signals:—

Fire Alarm, W. J. Schweiger, New York, 489,237. Filed July 11, 1892.

A concealed alarm adapted to be placed in the several rooms of a hotel, by which the guests may be alarmed from the office in case of fire and which will also display a card upon which are printed directions and means of escape.

Fire or Burglar Alarm, E. La France, Worcester, Mass, 489,312. Filed June 7, 1892.

Dynamos and Motors:—

Brush Holder for Dynamos and Electric Motors, R. Ashley, Philadelphia, Pa., 488,978. Filed Feb. 18, 1892.

Employs a spring actuated feed wheel to insure an equal pressure of the brush irrespective of the amount of material consumed.

Commutator for Dynamos and Electric Motors, H. Groswith and R. Ashley, Philadelphia, Pa., 489,000. Filed Feb. 18, 1892.

A disc commutator so arranged that any section may be readily removed without interfering with the others.

Transmitting Mechanism for Motors and Dynamos, H. W. Morton, Boston, 489,026 Filed Sept. 1, 1890.

Claim 1 follows:

The combination of a driving and a driven pulley, one of which is smaller than the other, with an idler provided with means for adjusting radially toward the smaller pulley so as to pinch the belt between the said idler and said pulley.

Alternating Current Dynamo, J. J. Wood, Ft. Wayne, Ind., 489,065. Filed July 22, 1892.

Employs a revolving multipolar field and a stationary ring armature; the field consisting of an axial core, an exciting coil around the core and alternated polar arms radiating from the opposite ends of the core, bending back around the coils and having their portions terminated in poles adjacent to the armature.

(See THE ELECTRICAL ENGINEER, Jan. 11, 1893.)

Armature for Electric Motors or Dynamos, C. F. Daniels, Macon, Ga., 489,070. Filed Dec. 2, 1891.

An armature composed of separate bobbins surrounding an axis to which they are secured by end plates and wedge-shaped clamping pieces.

Field Magnet for Electric Motors or Dynamos, C. F. Daniels, Macon, Ga., 489,071. Filed Dec. 2, 1892.

A field magnet consisting of two or more pieces of iron hollowed out to form cores bolted together.

Electric Motor, H. Illig, Bockenheim, Germany, 489,161. Filed Jan. 7 1892.

Comprises a solenoid in the main circuit, a current indicator connected with the core of the solenoid, a weight suspended from the core, an oscillating lever with a motor for actuating it, transmitting mechanism operated by the lever, and a registering device operated by said transmitting mechanism.

Commutator Brush Holder, C. F. Goodrich, Chicago, Ill., 489,185. Filed Dec. 29, 1891.

Employs means for controlling the pressure mechanism without detaching the holder from the machine.

Dynamo Electric Machine and Motor, W. T. Goolden and L. B. Atkinson, London, England, 489,302. Filed Aug 18, 1891.

Employs an air-tight non-magnetic casing surrounding the armature, having a jointed supplemental portion surrounding the commutator and brushes, and carrying the bearings.

Heating:—

Electromagnetically Heated Receptacle, W. Mitchell, Malden, Mass., 489,318, Filed Mar. 15, 1892.

Lamps and Appurtenances:—

Electric Arc Lamp, E. Thomson, Swampscott, Mass., 489, 046. Filed February 4, 1892.

Designed to operate on the stoppage of the feeding of the upper carbon due to its consumption or to its catching or holding up abnormally.

Electric Lantern, A. Keil, McKeesport, Pa., 489,150. Filed May 11, 1891.

Incandescent Lamp Socket, G. C. H. Foster, Bridgeport, Conn., 489,158. Filed Feb. 8, 1892.

Lamp Support, C. N. Wilcox, Brooklyn, N. Y., 489,172. Filed Jan. 28, 1892.

Measurement :—

Electrical Measuring Instrument, J. H. F. Görges, Berlin, Germany, 489,249. Filed Oct. 28, 1892.

A measuring instrument adapted for use with very heavy currents.

Metal Working :—

Electric Metal Working,, C. R. Arnold, Sharon Hill, Pa., 489,114. Filed May 17, 1892.

Claim 1 follows:

The herein described improvement in metal working by the electric arc consisting in setting up an extra or induced current in the circuit of the arc.

Miscellaneous:—

Elevator Indicator, N. Hiss, Baltimore, Md., 489,005. Filed Mar. 24, 1892.

Apparatus for Regulating Temperature, J. E. Watts, Lawrence, Mass., 489,052. Filed April 23, 1892.

Thermometric Indicator, C. R. H. Erkens, Lakewood, N. Y. 489,075. Filed Sept 15, 1892.

Operating Device for Bridge Gates, E. Zaremba, Chicago, Ill., 489,118. Filed March 5, 1892.

Temperature Indicator, J. Bartlett, Toledo, O., 489,212. Filed August 23, 1892.

Amalgamator, H. Calhoun, Hot Springs, & A. M. Beam, Bear, Arkansas, 489,216. Filed June 30, 1892.

Claim 1 follows:

In combination with an amalgamating vessel an electric generator connected therewith and adapted to deliver an interrupted current of constant direction.

Telegraphs :—

Telegraphy, Z. P. Hotchkiss, Oak Park, Ill., 489,435. Filed Apr. 18, 1891.

Employs a recording ribbon perforated by a stylus, actuated by an electromagnet, and a second stylus following in the line of the first, by means of which the perforations made by the first are enlarged.

Telephones and Apparatus :—

Telephone Switch, J. C. Francis, New York, 488,993. Filed Feb. 15, 1892.

Consists of a rotatable hook for supporting the telephone receiver, having a shaft rotating with it and bearing a commutator in contact with brushes for automatically cutting out the signal device when the receiver is removed from the hook.

Testing Apparatus for Multiple Switchboards, C. E. Scribner, Chicago, Ill., 489,098. Filed June 19, 1888.

A "busy" test for telephone central stations.

Testing Apparatus for Multiple Switchboards, C. E. Scribner, Chicago, Ill., 489,099. Filed June 19, 1888.

Similar to 489,098.

Test-Circuit for Multiple Switchboards, C. E. Scribner, Chicago, Ill., 489,100. Filed Mar. 1, 1890.

Similar to 489,098.

Telephone Switch Appliance, P. Rabbidge, Sydney, New South Wales, 489,266. Filed Jan. 2, 1892.

Employs a reversible vessel, insulated end plugs, a set of contacts extending through the plugs into the vessel, and mercury within the vessel.

Electromagnet, R. Varley, Jr. Englewood, N. J. 489,277. Filed June 13, 1892.

Employs a double winding for the magnets; one wire being bare and its successive convolutions separated one from the other by those of the second wire, which is insulated. See page 75.

Combination Fuse Box, W. F. Bossert, Utica, N. Y. 489,364. Filed Dec. 14, 1892.

Claim 2 follows:

The combination of the movable conductor, a movable supporter therefor, a catch for securing the supporter, and a fuse wire holding the catch.

Valve Controlling Clutch, J. P. Tirrell, Boston, Mass., 489,424. Filed Mar. 7, 1891.

Has for its object to enable the armature of an electromagnet to act as a coupling device to engage an electric clutch with the pulley, and thus cause one of the parts to give motion to the other.

Case for Electrical Measuring Instruments, E. Weston, Newark, N. J. Design 22,101. Filed Dec. 7. 1892.

Railways and Appliances :—

Trolley Wire Support, G. H. Scranton & L. Spillman, Columbus, O.. 489,097. Filed May 27, 1892.

Consists of a plate having a rounded lower side and a grooved upper side, in which the trolley wire lies, and a bracket arm overhanging the plate for the purpose of suspension.

Fender for Electric or other Cars, M. S. Starkweather, Boston, Mass., 489,207. Filed July 18, 1892.

Electric Railway Trolley, J. Reutlinger, St. Louis, Mo. 489,234. Filed July 30, 1892.

Claim 1 follows:

A trolley having teeth arranged on the side and insulated from the body portion.

Electric Elevated Railway, A. L. Rutter, Washington, D. C., 489,330. Filed Feb. 20, 1892.

An electric railway employing cylindrical cars suspended from an overhead track.

Underground Conduit for Electric Railways, C. P. Tatro, Spokane, Wash., 489,422. Filed Mar. 23, 1891.

Relates particularly to means of communication between the rail and the line wire, and also means for mounting the trolley carriage upon wheels in the conduit, and connecting it with the car by a flexible conductor.

NEVER FAILS TO RECOMMEND IT.

A Southern electrical railway builder and engineer writes us in renewing his subscription:—"You well know my high appreciation of your valuable paper; and I never fail to recommend it to those looking for an electrical journal."

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

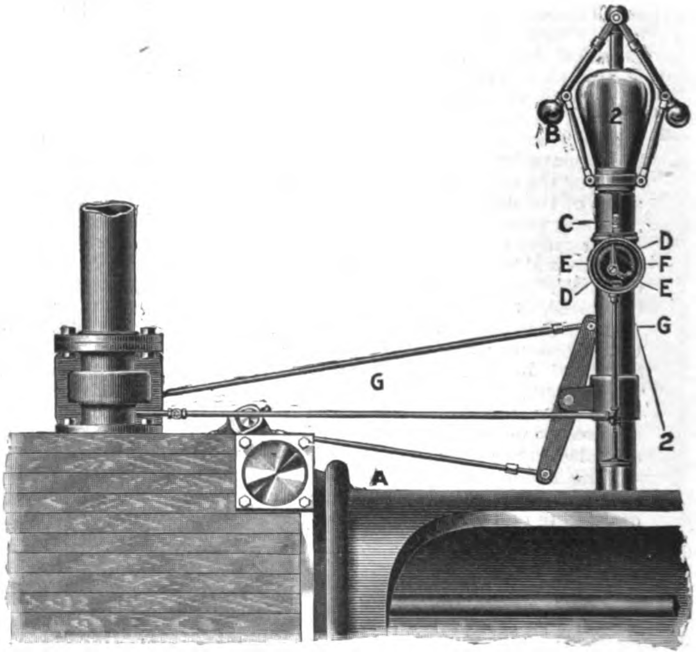
THE BARCLAY AUTOMATIC GOVERNOR STOP.

The accompanying illustration shows James Barclay & Co.'s automatic safety governor stop for the Corliss engines, manufactured by the Sioux City Engine Works, of Sioux City, Iowa.

The engine is provided with the usual governor connected with the valve mechanism of the Corliss type of engine, or with the valve stem of throttling governors. The governor is provided with its usual sleeve C adapted to rest on a stop made in the shape of a lever when the steam is shut off by the engineer. When, however, an accident happens to the governor, while the engine is running, the stop D being moved from under the sleeve permits the governor to drop sufficiently to completely shut off the steam from the engine.

The lever is fulcrumed within a casing attached to the support of the governor, and provided with an extension pivotally connected by a link with the closed end of a spring tube F, bent in the shape of a segment of a circle, and connected at its open end with a pipe G leading to the supply pipe or other part of the steam chest.

It will be seen that when the steam passes through the pipe G into the tube F the latter swings outward at its free end, thus exerting with this free end a pull in the extension of the lever whereby the latter swings from under the sleeve C to permit the latter to drop below its normal position in case of accident to the governor. As soon as the steam is cut off from the pipe G by closing the valve in the inlet pipe to the cylinder, then the tube F is relieved of the pressure and consequently its free end contracts so as to move the lever back to its normal vertical position, to support the sleeve C in a normal position.



Barclay Automatic Governor Stop.

THE BISHOP GUTTA-PERCHA COMPANY.

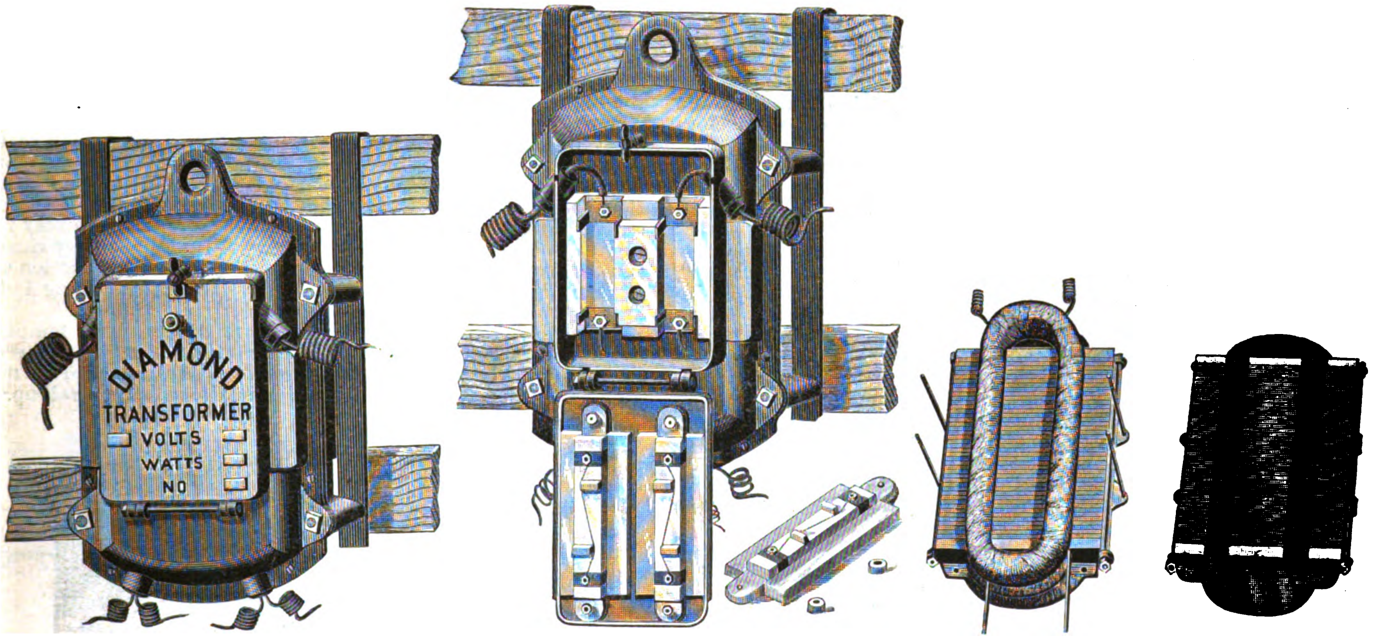
The Bishop Gutta-Percha Company, at a meeting of stockholders, held Jan. 11, reelected the old board of directors, Sam. Boardman, Helen E. Blitz and A. Spadme, and the board elected Sam. Boardman, president, Helen E. Blitz, vice-president, and Henry A. Reed, treasurer and secretary. Mr. Samuel Boardman, senior member of the firm of Boardman & Boardman, attorneys, 155 and 157 Broadway, has been concerned with the Bishop Company for more than 30 years, first as attorney for Mr. Bishop, then as attorney in fact, and agent for Mrs. Bishop and later as her executor. On closing her estate, in 1885, he organized the present company, and has since held the offices of president and treasurer. Henry A. Reed was employed by Mr. Boardman under his Executorship as an expert to prepare evidence in defence of a threatened suit for infringment of the Simpson patent and as accountant in settling the estate. On the organization of the company, Mr. Reed was made its secretary, and one year later its general manager. On account of the ill health of Mr. Boardman Mr. Reed has for several years been acting treasurer so that in receiving the title his duties are not changed.

THE "DIAMOND" TRANSFORMER.

It is only within a comparatively short time that transformers have been manufactured apart from generating apparatus. Practical experience, however, had suggested so many economies that might be effected by improved types of transformers, that about two years ago factories outside of parent companies were established for the exclusive manufacture of transformers and kindred articles.

The diamond transformer is the latest type of these independent efforts, and embodies, it is said, all that experience has obtained from the good qualities of other converters, while it is claimed to obviate all of their defects.

A transformer to be popular in these days with the superintendent of central stations and with linemen, must be convenient and unattended with any abnormal difficulties in placing upon poles or buildings. Our engraving, Fig. 1, illustrates the transformer as it appears when attached to the cross arm. It will be seen that this converter is easily adjusted and held in secure position by the hooks engaging with the cross arms. The ring in the top is for hoisting it upon a pole by means of a block and tackle. Should it be necessary, however, to attach the converter to a brick wall, the hooks may be easily removed and the converter secured to the wall by means of the four lugs seen in the cut. The diamond transformer is also made "three-point" and is easily and quickly convertible from 50 to 100 volts on the secondary wires without the use of a more or less clumsy and inconvenient switch.



Figs. 1, 2, 3 and 4.—The Diamond Transformer.

Fig. 2 shows the transformer with fuse box exposed to view. The primary and secondary connections are readily seen, and it will also be noticed that when the door is closed each fuse is in a separate compartment, so that in case one should blow out, it would have no effect upon the other by excessive heating. The porcelain box and fuse blocks are highly glazed, and it is claimed that there is no danger of their absorbing moisture. The convenience of this style of fuse box will thus be apparent. The fuse blocks are attached to the door itself; it follows that when the door is opened the connection is completely broken, and a lineman may replace fuses upon a live wire with perfect safety, at the same time having the fuse blocks entirely exposed to view. The fuse blocks themselves may be detached by means of a little knurled thumb-piece, seen by the side of the detached block. These fuse blocks are interchangeable for all sizes of transformers, so that a central station, by keeping a few of them on hand, may always be assured of a fuse block in case one upon the line should be destroyed by lightning or otherwise.

It has been a source of inconvenience and expense to central stations heretofore to return burned-out converters to their respective factories to be repaired or replaced. The delay has often caused serious inconvenience, and it has resulted in many cases in the largers tations making ineffectual attemps to repair the converters themselves. Figs. 3 and 4 illustrates one of the most important features of the diamond converter, which will be appreciated by practical central station men. It will be seen that the secondary coils are in two parts, the primary coil being securely embedded between the two, thus affording a common centre of magnetism. After the primary coil is in position the secondary coils are adjusted and firmly bolted together, completing a perfect magnetic circuit. Should, however, a primary coil be burned out by lightning or otherwise, it is only necessary to have another coil sent by express when the central station man can readily place it in position himself, thus obviating all the delay and expense which was a necessary part of the old methods.

The Diamond converter is of very high efficiency, low leakage current and excellent regulation. It is made as light in weight as is consistent with the best practice, and is well ventilated through the top and bottom of the case, so that a free passage of air will aid in keeping the coils at a low temperature.

Messrs. Taylor, Goodhue & Ames, 827 Monadnock Block, Chicago, Ill., have taken out the exclusive agency for the sale of this converter, and have in course of preparation a pamphlet treating quite extensively of its merits.

AN INTERESTING PLANT IN THE HICKOCK WORKS, HARRISBURGH, PA.

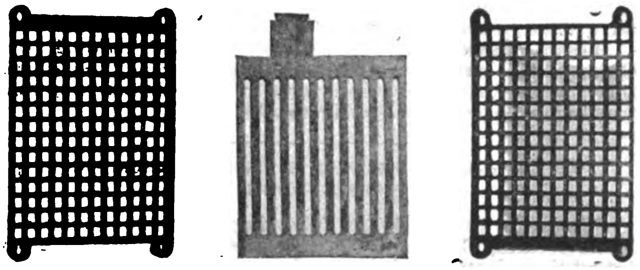
We are in receipt of the following from the W. O. Hickok Manufacturing Company, of Harrisburgh, Pa., who have a very interesting electric lighting and power plant in their factory, where bookbinders' machinery is made. The factory covers considerable ground in the form of a quadrangle, and was built in 1890, since which time the plant has been gradually increased:

"Our establishment is run by electricity. We have a machine department, which covers a floor space of about 250 x 80. The machinery in this department is arranged the full length of the floor in four rows; two rows of machines back to back on each side of a broad central aisle; two main lines of shafting run the full length of this department, one line over each double row of machines. About in the centre of each of these lines of shafting we have a small house built against the side wall, having glass in front and on either side, one side being occupied by a glass door. A slanting roof, tinned on the top, covers this motor house. Thus we protect the motors from injury by water in case of fire and keep them free from dust. In each of these motor houses we have a 20 h. p. 'C. & C.' motor, and we belt direct from each of these motors to their respective line shafts, thus dividing the power in our machine department in a most convenient form. We also conduct two floors in our wood-working department, and on each of these floors have a motor of the same make and size, housed in the same manner, one of these motors also giving power to a 10 x 15 foot platform, five-ton 'Graves' elevator. We are preparing to run our cupola fan and foundry rattler by independent motor. Our testing department supports several small motors. We have found that the 'C. & C.' motor has been so economical in the line of repairs, and has given so much universal satisfaction, that we are confining ourselves to that make.

"Our foundry, machine shop, smith shop, wood-working department, yard and office are all illuminated with electricity, We believe the division of power and arrangement of our plant gives the best and most economical result that we have had the pleasure of inspecting in the line of electric power for manufacturing purposes."

THE ACME STORAGE BATTERY CAR.

The Acme Storage Battery Company have equipped a car of the Ninth avenue street car line with a set of their batteries and have been conducting a series of tests on the road between 53d and 125th streets. A public test was made on Jan. 11, the car containing a number of representatives of the electrical and daily press, and doing its work very creditably, notwithstanding the very slippery condition of the tracks.



Acme Storage Battery Plates.

The equipment consisted of 144 cells, arranged in 12 boxes, six on either side of the car, the whole weighing 8,500 pounds. The car had a Baker truck and a McDougall motor capable of developing 30 h. p.

The Acme cell weighs 27 pounds against 40 pounds for a cell of the same dimensions using lead grids. The grids are of a non-conducting material which is not attacked by the acid and which is sufficiently elastic to yield to the expansion of the active material without buckling, warping or breaking. On the other hand, the active material is retained with sufficient firmness in contact with the conducting plate of lead which is situated in the middle of the complete plate. There is an equal amount of active material on each side of this lead conducting plate, thus ensuring an equal distribution of current. The form of the grids is shown in the accompanying illustrations.

Ribs on the non-conducting grids meet through slots in the conducting plate, and are cemented together, uniting the whole into one solid plate. The openings for the reception of active material are smaller on the outside to aid in the retention of their contents. The exposed surface of active material is about 40 square inches on each plate or about 200 square inches for the five positives.

During the test a grade of six per cent. half a mile long was climbed. The maximum steady discharge on this hill was 130 amperes or about .65 ampere per square inch.

THE JOSEPH DIXON CRUCIBLE CO.

The Joseph Dixon Crucible Company, of Jersey City, are taking time by the forelock by putting up a fifth story, 175 x 75 feet, on their pencil factory. The new addition will be equipped with new and improved pencil machinery of their own invention. The Company will also establish a rubber and brass plant for the manufacture of the various pencil accessories and novelties. As it was only in 1891 when the Dixon Company put extensive additions on their crucible and black-lead works, and erected offices which for size and beauty are second to none in the State, it seems evident that prosperity claims the Dixon Company for its own.

E. W. BLISS CO.

This company, of 17 Adams street, Brooklyn, N. Y., report that the past twelve months have witnessed by far the greatest enlargement and most extensive improvements in their works that have taken place during the history of the concern. After amalgamating with their business that of the Stiles & Parker Press Co. it was decided to move the entire plant of the latter company to the Brooklyn works. Partly to accommodate the increase of business in that direction, an additional building was erected 150 feet long by 90 feet wide and six stories high. The machine shops now occupy the entire block bounded by Adams, Pearl, John and Plymouth streets, and enclose in the centre an erecting shop for heavy machinery, spanned by a 25-ton electric traveling crane. A large number of new machine tools have been put in, and some large, special boring and milling machines are being built.

The company have also equipped a portion of the works with special machinery for the manufacture of Whitehead torpedoes and torpedo guns, which they are making on contract with the United States Navy Department. The development of this branch of business has called for much mechanical skill and elaborate investigation, not to speak of the large investment. All departments have been well filled with orders during the year, the prospects are thoroughly good, and they expect to make still further extensions of their already large facilities.

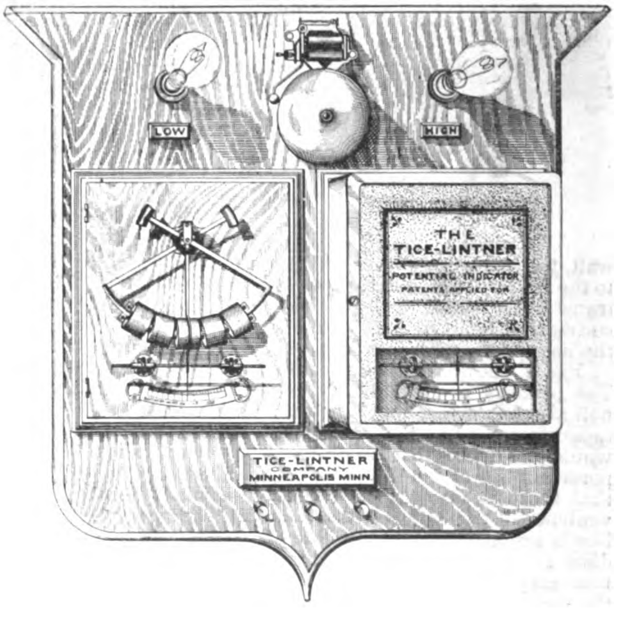
THE TICE-LINTNER POTENTIAL INDICATOR.

Recognizing the necessity of close potential regulation, and believing that with more perfect regulation, lamp breakage would be reduced to a minimum, the Tice-Lintner Electric Company, of Minneapolis, have brought out an instrument which combines with a voltmeter of the highest degree of accuracy, permanency and dead-beat qualities, an alarm attachment of equal reliability which immediately attracts the attention of the attendant to any change or variation in pressure. Red and green lamps to indicate whether the pressure is high or low, are provided and lighted simultaneously with the ringing of the alarm bell.

The accompanying engraving shows a general view of the instrument adopted for the three-wire system. The instrument is wound in such a manner as to produce a field of the greatest intensity, with the lowest possible temperature co-efficient and contains nothing in its make-up subject to change or deterioration. The intensity of field results in the indicator being little affected by the close proximity of circuits carrying heavy currents or by other similar disturbing agencies so troublesome to most measuring instruments. In its construction it has been the aim of the inventors to concentrate the action within the normal limit of the system on which it is placed, so as to give to the index arm the requisite degree of force essential to a circuit-closing device.

Two delicately-balanced armatures of the softest obtainable iron, to one of which is attached the index, are acted upon by the magnetic field of a curved solenoid in such a manner as to form opposite poles at their contiguous extremities, the mutual attraction of which greatly augments the directive force of the solenoid. This attractive force of the iron cores increases very rapidly as they approach and diminishes as rapidly as they recede, thus giving to the instrument the greatest delicacy of action and securing wide range of movement to the circuit-closing index arm for the slightest change of potential.

The alarm circuit, together with that of the signal lamps, is completed through one of the platinum-tipped contact points set on either side of the index, and which are adjustable, by turning a milled head, to any desired range, from a fraction of a volt up. If desired, the contact points may be removed to the extreme ends of the scale to permit of using the instrument as a voltmeter.



The Tice-Lintner Potential Indicator

The indicator is now in successful operation in some of the largest lighting plants in the country, and its introduction has been attended with a marked diminution in lamp breakage, as there can be no perceptible increase of potential without the dynamo attendant being immediately apprised of the fact and the same remedied before any damage ensues.

THE VARLEY DUPLEX ELECTROMAGNET.

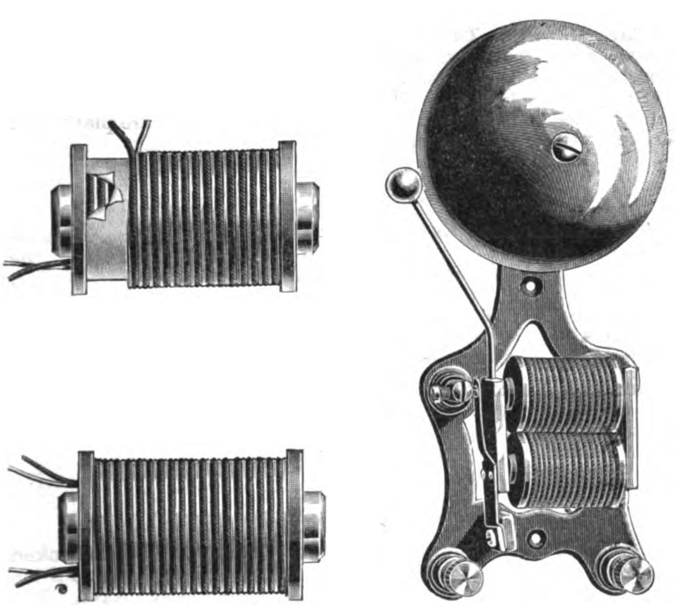
BY

McSullivan.

At a time when the electrical community is practically at a standstill so far as the invention of novelties is concerned, it is pleasant to know that the inventors are not idle and that the patent office continues to turn out its usual quota of patents relating to electricity in its varied applications.

Most of the patents of late however have been of a specific character and either relate to improvements in the quality of the article or cheapness in its method of manufacture. Among the latter is one relating to a new method of winding electromagnets and called by its inventor, Richard Varley, Jr., the duplex method.

This method of winding magnets is a novel one and is a wide departure from the methods heretofore in vogue. Fig. 1 shows a magnet in section, with a portion of the interior exposed. It will be seen that a bare and an insulated wire are wound simultaneously, the insulation of the covered wire serving the purpose of keeping the turns separated, and paper being used between each layer. This method necessitates the use of a machine which has been designed for the purpose. The magnet when completed has four ends, and these, in the case of a simple magnet, are connected in series, or in multiple in the case of galvanometer coils, etc., where a differential circuit is required. This is easily accomplished, the very nature of the method of winding making it possible to have any combination of circuits, series, parallel or differential. Fig. 2 shows a magnet complete and Fig. 3 an ordinary bell with duplex magnets. Owing to the fact that insulated-magnet wire in the smaller sizes costs about twice as much as bare wire of the same size, it will be seen that with one-half the wire on every magnet by the duplex method being bare, a considerable saving in the cost of wire is effected, even if the number of feet of wire were the same as if all insulated wire were used; but, as this method makes the magnet more compact, the required number of turns are secured in a smaller space, and a saving is effected in the amount of copper used when considered by weight, or in price when considered from the standpoint of insulation.



Figs. 1, 2 and 3.—Varley Duplex Electromagnet.

When one stops to consider, it seems unfortunate that as the many convolutions on a magnet where the current is slight, as in the majority of smaller magnets, have only to be separated an infinitely short distance from each other, this distance is of necessity made much greater than is actually needed, because of mechanical reasons.

Magnet wire is usually covered with some fibrous insulating material in the form of yarn, and this in order to stand the strain of the winding machinery must be of sufficient tensile strength. This consideration, of course, being a necessary one, we find that a wire when insulated has a very much increased diameter, and the insulation is much thicker than would be put on for this service if no other than electrical considerations were to prevail. As the diameter of the wire is increased it requires a greater amount of wire to get the necessary number of turns to give a magnet the required strength, and the complete magnet is much larger than if it were possible to use a wire of a smaller diameter. These conditions are practically the natural result of winding magnets as it is done at the present time. The manufactured magnets, when all insulated wire is used, are quite at variance with the principles which govern the operation of this device when looked at from a scientific standpoint, that of an ideal electromagnet.

An electromagnet approaches its ideal efficiency when all the limiting space around the iron core is occupied by energizing current, without any intervening air-space. This, of course, can only be accomplished when the limiting space is occupied by but one turn, in which case no losses are due to insulation. When a departure is made from this theory the losses increase as the number of turns which have to be put on to get the required saturation. In other words the nearer we approach the utilization of the available space around the core, as completely as possible, with nothing but a conductor, the nearer we approach the ideal magnet from a standpoint of economy as well as efficiency. This condition would render the length of wire as small as possible, because the diameter of the successive layers being decreased, it takes less wire to secure the required number of windings. Conditions, of course, known as ideal are as a rule impossible to obtain in practice, yet, at the same time, it will be seen that Mr. Varley's process is a great step in advance of the present usages in this department of electrical manufacture. It is a step that affects this branch of manufacture more than would appear at first sight, because, as before stated, the cost of manufacture is materially reduced. The valuable space that is gained by dispensing with one-half of the insulation renders it possible to make the magnet more compact, thus making a great step forward toward what may be considered the ideal magnet. In the case of such apparatus as fire alarms, railway-signals, and the telephone service where the element of space is an important consideration, the duplex method, which makes a magnet smaller without decreasing its strength will be of great value in these fields alone, if from no other consideration. The machine for making these magnets was designed by Mr. Varley, and, being automatic to a great extent in its action, uniformity in the magnets made on it is but a natural result.

The Varley Duplex Magnet Company has been organized for the purpose of introducing this invention, with offices at No. 136 Liberty street, New York City.

A NEW FACTORY FOR THE GIANT ELECTRIC MOTOR COMPANY.

A Portland, Me., newspaper says: "The second grand boom for our village cousin on the other side, and one that will add nothing to the very active appearance of Portland, will be the removal of the Giant Electric Motor plant from Commercial street to one section of the Mussey farm at the Cape Elizabeth. Plans have been laid for the erection of four large two-story buildings in the direction from the plush mill toward the ferry slip. The buildings will be of iron with brick interior, and will be built by the Berlin Iron Bridge Works, of Berlin Falls, Connecticut. The dimensions of each building will be 150 by 75 feet, and will cost $25,000 each. The architect is Elmer J. Thomas, of Auburn. The work on the first building will be started as soon as the ground is in a fair condition for breaking which will probably delay the matter of laying the foundation until spring. It is further proposed, according to the plans that have been drawn, to later adjoin the second building of 150 by 75 feet to the first building of the same dimensions. A short distance away a third building of the same dimensions as the two others will be erected, and eventually a fourth building adjoined to that, making two immense double iron edifices. Several sets of machinery run by as many motors, will be put in operation instead of one long shafting with a single motor supplying the power. It is thought by this that considerable power that is lost by the use of long shafting will be saved, and in case of a break down of any single motor the machinery will continue and work would not be suspended. An electric crane something like the one now in use at the Portland Company, and which will cost the big sum of $10,000 is to be one of the features of the plant. Six months ago there were seven men employed in the Giant Electric Motor Company, and but a small plant. To-day there are 50 skilled workmen employed while the machinery has been increased until it is now seven times larger and valued in proportion. While some of the credit is due to the men at the head of it, considerable praise must be credited to Superintendent Upp who has succeeded in bringing the work to so high a standard. Among the contracts now on hand is one to supply 10,000 arc and incandescent lights in the White Mountain region this coming spring at a cost of $60,000."

LECLANCHÉ BATTERIES.

Mr. R. Aylmer, of 47 Victoria street, London, England, has been appointed sole concessionaire for the manufacture and sale of Leclanché batteries in Great Britain and the Colonies, and has issued an interesting catalogue descriptive of various styles of these well known cells.

MESSRS. WATERHOUSE, GAMBLE & CO.

The Waterhouse arc lamp, which, it will be remembered, was described and illustrated in our columns some months since, has passed beyond the experimental stage and seems to have warranted all the confidence reposed in it. Messrs. Waterhouse, Gamble & Co., of 45 Broadway, this city, are now manufacturing these lamps on a commercial scale and have received many testimonials from users in regard to their satisfactory working. They are now prepared to furnish a single carbon lamp for ⅝-inch carbon to burn 15 hours, as well as lamps adapted to burn on circuits of variable E. M. F., by means of an automatic regulating device. They also make various forms of resistance hangers for lamps under different conditions.

MARQUAND, SKEHAN & CO.

The banking and brokerage firm of Marquand, Skehan & Co., of 16 Broad street, which has already made a distinct place for itself in the *haute finance* of Wall street, has begun the New Year under brighter auspices than ever. It has now admitted to partnership Mr. Abram C. Bernheim, late of the firm of Bernheim, Bauer & Co. The style of the firm will remain unchanged, but as the new member is connected with the influential management of the Manhattan Electric Light Company, the firm will be in an even more advantageous position for enjoying a practical control of dealings in local electric light stocks.

500-VOLT MOTOR CIRCUITS.

With regard to the recent discussion in our columns of the growing use of 500-volt motors, the Motor Department of the General Electric Company writes us:

> For two years past we have been putting in 500-volt circuits for power purposes and have them now fairly well distributed throughout the country. Nearly every town of any size has a 500 or 220-volt circuit. Boston has both 220 and 500-volt circuits, but the demand in this city is largely for 220-volt machines, although the company controlling the 500-volt circuit is now pushing out for power work. In Providence a 500 volt circuit has been operating for two years, and we now have between 500 and 600 h. p. in motors on it.

A COMMERCIAL CABLE SOUVENIR.

The Commercial Cable Company has issued to its friends a very handsome souvenir in keeping with the recent holiday season. It is in the form of a card with the customary holiday greeting, and contains a well-executed picture of the company's offices at Wall and Broad streets as they appeared during the Columbus Quadri-Centennial Celebration. The tasteful decorations of the structure, which won so much merited praise during the celebration, are well brought out in the card.

WIRE AND WIRE ROD MILLS' COMBINATION.

A special dispatch from Pittsburgh, of Jan. 8, says that a deal is being engineered to consolidate the wire, wire nail and wire rod interests in the United States. If the combination can be effected it will be one of the biggest concerns in the country. The capitalization will be $25,000,000.

The proposition comes from the Washburn-Moen Company, and was made to the Consolidated Company, with headquarters in Pittsburgh and Chicago. A barbed-wire trust was organized about three months ago, but the idea is to wipe out the limited consolidations and unite all in a grand combination that will regulate the output and maintain prices.

WESTERN NOTES.

The Central Electric Co., 118 Franklin street, find that the demand for Interior Conduit and Lundell motors is considerably on the increase. They have devoted a department exclusively to the manufactures of the Interior Conduit & Insulation Co., New York. Mr. H. H. Small, for some years manager of the Western supply department of the Thomson-Houston Electric Co. will assume the charge of this new department.

Mr. Harry Bishop, formerly New England agent of the *Street Railway Gazette*, has accepted the position of Western sales agent for the Massachusetts Chemical Co., with offices at 823 The Monadnock Building. Mr. Bishop comes well recommended, and will doubtless build up a fine business for the "Insullac" people in the West.

L. H. Hart, formerly business manager of the W. J. Johnston Co., spent several days in Chicago recently in the interests of the new journal, *Heating and Ventilation*, of which he is business manager. He renewed some old acquaintances in the Rookery, and of course called on the Engineer. All wish him success in his new venture.

Mr. H. M. Swetland, president of the *Power* Publishing Co., was a welcome caller at the office this week.

The Chas. E. Gregory Company, capital $50,000, has been formed with Chas. E. Gregory as manager, to deal in complete steam and electrical equipments. The wonderful growth of Mr. Gregory's business during the last year has necessitated this move so that he may be able to handle the immense business now enjoyed.

Mr. H. M. Linnell, managing director of the Automatic Telephone & Electric Company, of Canada, with office in the City of Montreal, has been in this city for some days. There is considerable stir in Strowger telephone matters in Canada, and several important exchanges are well under way.

Mr. W. Taylor, of Taylor, Goodhue & Ames, has an interesting New Year's article on electrical development, in the Chicago *News-Record.*

PHILADELPHIA NOTES.

"Queen & Company, Incorporated."—Among recent business changes of special interest to the electrical fraternity is the transferring of the business of James W. Queen & Co., Philadelphia, to a stock corporation bearing the title Queen & Co., Incorporated. The new company starts with a paid capital of $600,000, which will be increased from time to time as may be required for the extension of its numerous interests, which in addition to electrical measuring instruments now comprise scientific apparatus of every description. The incorporators and Directors for 1893 are S. L. Fox, E. B. Fox, J. G. Gray, W. Biddle, Jr., J. G. Biddle, and F. W. Stanwood, all of whom have been actively connected with the old fim. E. G. Willyoung continues as superintendent of the electrical laboratory.

The Scranton Traction Co., of Scranton, Pa., have placed the contract for the buildings of their new plant with The Berlin Iron Bridge Co., of East Berlin, Conn. The boiler and engine room will be 65 feet wide by 200 feet long, with a machine shop and car shed 93 feet wide by 225 feet long. The entire plant will be fire-proof, of the well-known Berlin construction.

NEW ENGLAND NOTES

The Berlin Iron Bridge Co., of East Berlin, Conn., have secured the contract for a new iron fire-proof store house for the Pope Mfg. Co., at Hartford, Conn. The building will be 40 feet wide by 84 feet in length, two stories high, and will be used for storing the separate parts of bicycles, as the Pope Company have to carry a very large stock of the different parts to supply the wants of the numerous users of the Columbia safety.

The New York Insulated Wire Co., has opened a branch office at 182 Summer Street, Boston, where it will carry a full stock of all its specialties for the New England trade. Mr. Walter S. Barker will be the selling agent.

NEW YORK NOTES.

The E. P. Gleason Manufacturing Company have just broken ground for the erection of a four-story building to be an addition or extension to their already large glass works in Brooklyn. The new buildings will be used principally for finishing glassware for illumination, *i. e.*, polishing, cutting and etching the articles after they have gone through the glass house proper. The company have erected two buildings last summer to increase the output of their glass factory, and this building is now necessary, as their finishing shop, which at present consists of a three story building, 100 feet front x 150 feet deep, is too small for the increasing trade of the company.

CANADIAN NOTES.

The Packard Lamp Co., Ltd., of Montreal, notwithstanding the fact that they recently more than doubled the capacity of their factory, are contemplating its further enlargement in order to be able to meet the demand for their lamps, for which orders are coming in faster than they can be filled. The factory of this company, Nos. 96 to 100 King street., Montreal, is equipped with the most improved machinery for the manufacture of incandescent lamps of any candle power and voltage, to fit any base. The lamps manufactured there are the latest improved "Packard High Grade" incandescent lamps, similar in all respects to those made by the New York and Ohio Co., at Warren, Ohio, and are meeting with the greatest success among the Canadian trade, as is shown by the continually increasing demand for them throughout the Dominion.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

Electrical Engineer.

Vol. XV. JANUARY 25, 1893. No. 247.

THE CARBON FILAMENT LAMP OF 1859.—THE STORY OF AN OVERLOOKED INVENTION.

BY

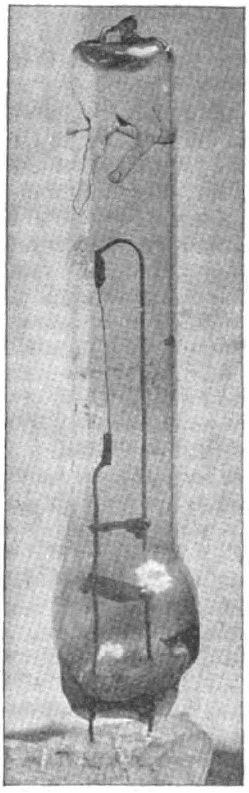
Franklin Leonard Pope

Incandescent Lighting, Union Square, 1859.

THERE will probably be more than one reader of this article, whose memory of street-scenes and incidents in the city of New York runs back thirty years or more, to a period "just before the war," who will recall, among the various well-known street spectacles of that day, a peripatetic astronomical observatory, which might frequently have been seen in the full tide of successful operation on pleasant evenings, in one of the open spaces of the up-town streets, perhaps more often than elsewhere in Union Square, or in the vicinity of the Cooper Institute. This establishment consisted of a four wheeled wagon, between the shafts of which stood a pony usually contentedly munching a wisp or two of hay; and a refracting telescope, fifteen or twenty feet in length, mounted upon the wagon, with its eye-piece in convenient proximity to the ground and its opposite extremity directed towards the constellations of the firmament. The exhibitor, a kindly-faced, middle-aged German, with the manner of a gentleman as well as of a student and a philosopher, could usually be heard enthusiastically discoursing, in picturesque English with a strong Teutonic flavor, to an assemblage of all sorts and conditions of men, women and children, upon the wonders of the starry heavens, and upon the remarkable phenomena which might be seen by those who were sufficiently curious to pay a small fee for the privilege of gazing through the telescope at the various celestial objects within its range. The philosopher was usually accompanied by a small boy, whose duties consisted principally in looking after the pony, and in officiating as assistant cashier, when business was brisk. Whenever the interest of the auditors began to flag, or they evinced too great a tendency to straggle away, their attention was not infrequently aroused anew by the sudden flashing out from the obscurity behind the driver's seat, of two or three brilliant lights of mysterious origin and appearance, which were explained to be caused by the action of electric batteries concealed in a couple of large chests at the front and rear of the wagon. The exhibitor was accustomed to speak of these pieces of apparatus to his motley audience with pardonable pride, for not only the telescope, even to the shaping and grinding of the lenses, but the mysterious electric lamps, and the batteries by which they were brought into action, were the work of his own hands.

Then followed the fateful years of the war of the rebellion, and in the frenzied excitement of rapidly recurring events at the front, the milder diversion of star-gazing lost its power to charm. The telescope wagon with its owner disappeared, and the places that had known them knew them no more. But now, after the lapse of a generation, the almost forgotten astronomer of the boulevards suddenly finds himself the centre of attraction in the world of electricity, for in some of the still existing electric lamps of that former time, modern science recognizes, not only the general principle, but most of the details of construction as well, which go to make up the incandescent electric lamp of to-day.

It is a trite saying that "truth is stranger than fiction," and surely nothing could be more strange and more dramatic even, than the unexpected discovery, almost at the very moment of the final decision which marks the termination of years of protracted and costly litigation, of a pre-existant lamp embodying the very principles, nay the very forms, of the invention so long in controversy, accompanied with what must be admitted to be almost irrefutable evidence that it had been made and publicly exhibited to hundreds if not thousands of people in the streets of the metropolis, more than thirty years ago.



Goebel's Carbon Filament Lamp of 1859.—"Meat Saw" Type.

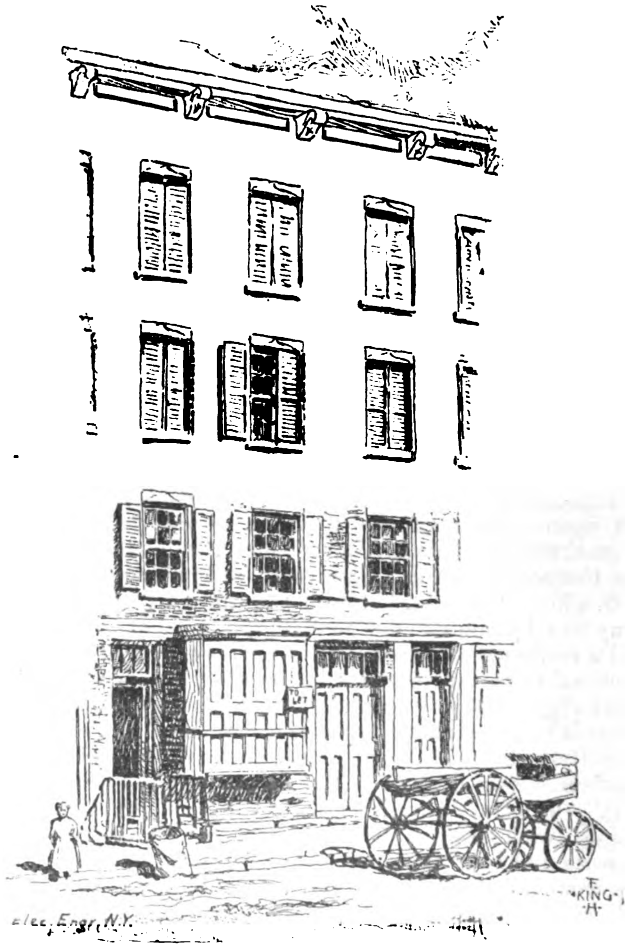
Heinrich Göbel was born in the little village of Springer, a few miles from Hanover, Germany, on the 20th of April, 1818. His father, Friedrich Göbel, was a manufacturer of chocolate, and a man of some prominence in the community in which he lived. He was for a time, about 1819–

20, Consul for the Netherlands in New York. Heinrich received a tolerably good education in the Lutheran Church school of his native village. Having a marked predilection for the study of physical science, he was not content to pursue his father's business, but preferred that of a watchmaker and optician, which he learned after some preliminary experience as an apothecary's assistant, and subsequently carried on on his own account in Springer.

Having in the course of his business, frequent occasion to repair philosophical apparatus for the instructors in the Technological School of Hanover, he soon became much interested in physical research, in which he was aided and encouraged by one Professor Mönighausen, a tutor in a neighboring wealthy family, for whom he made various pieces of apparatus, and who was accustomed to spend a great deal of his leisure time in Göbel's little shop. In 1846 the technical journals of Europe published accounts of the now well-known electric lamp invented by J. W. Starr, of Cincinnati, in which a brilliant light was obtained by the incandescence of a thin rod of carbon enclosed in a Torricellian vacuum. As Göbel was well skilled in the construction of barometers and thermometers, Professor Mönighausen often discussed with him the possibility of making an electric lamp on this principle, and they even went so far as to make some experiments in this direction, but without successful results. During this period Göbel also made galvanic batteries and electromagnetic apparatus, as well as a small magneto-electric machine. He continued, however, to work industriously at his trade, and relates that after having finished a number of clocks, he was accustomed to take them to Hanover on market-day, and expose them for sale in the market place where they were usually soon disposed of.

In 1848, being then thirty years of age, Göbel determined to seek his fortune in the United States. After a tedious voyage of over three months in a sailing vessel, he landed in New York, and in a short time had established himself in his business in a little shop in an obscure neighborhood near the Grand street ferry, where he remained for more than twenty years. He found himself able to support his family in comfort from the proceeds of his business, and in a position to devote considerable time to his favorite occupation of making experiments and inventions. Within three or four years after his arrival in this country, he had constructed a zinc-carbon battery of about 80 large cells, by the aid of which he astonished the neighborhood one dark night by exhibiting from the roof of his house, an electric arc formed between two pieces of carbon. The experiment was, in fact, altogether too successful, for an alarm of fire was sent in, and the department, headed by the historic "Big 6," promptly appeared upon the scene. Being unable to locate the fire, they caused the philosopher to be arrested and carried before a police justice charged with a breach of the peace.

It is possible that the unpleasant results of this experiment may have led Henry Goebel as he thenceforth preferred to be called, to turn his attention in the direction of incandescent lighting. At all events, he undertook to put into practice some of the suggestions of his friend Prof. Mönighausen. He had noticed, in trying to burn a piece of wood out from the ferule of a broken walking stick, that some portions of the wood from which the air was excluded by the ferule were carbonized, and upon testing a piece of this carbonized wood he found it to be a conductor of electricity. This suggested to him the employment of wood fibre, carbonized in a similar manner, for the light-giving conductor of the lamp. Among various woody materials tried, were splinters from a bamboo pipe-stem, which were found to answer admirably. As early as 1855, Goebel had succeeded in making quite a number of lamps, which, by the use of about 30 cells of zinc-carbon battery, emitted, for a short time, a brilliant and beautiful light. A number of these old lamps have fortunately been preserved, and an example of one of the earlier forms, which Goebel called his "meat-saw" lamp, is shown in the accompanying illustration, which has been photographed directly from the lamp in its present condition.

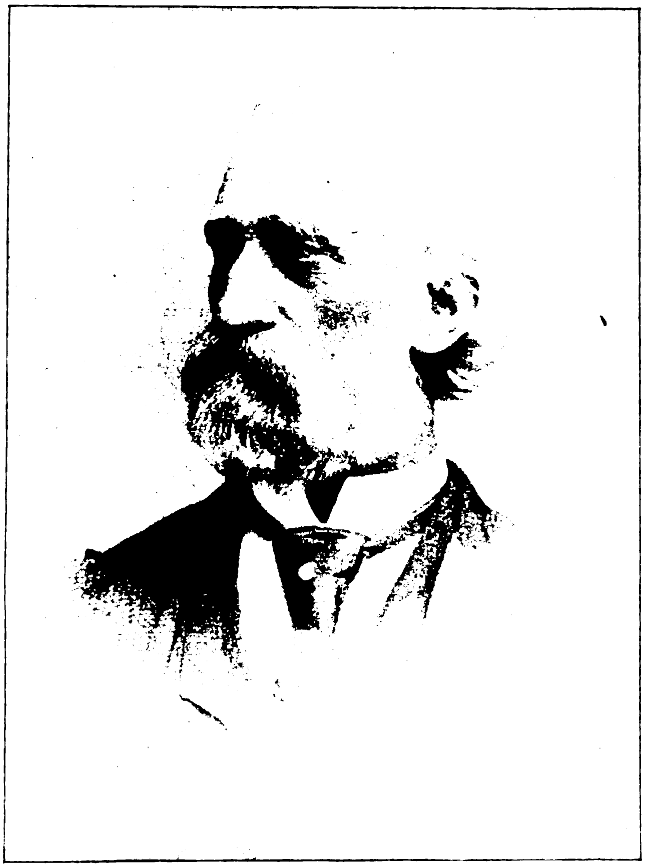


House in Monroe Street, New York, Where Goebel Made His Incandescent Lamps in 1859.

A critical examination of this lamp reveals many surprising anticipations of what have been regarded as distinctively modern discoveries in electric lighting. The chamber of the lamp, which is formed from a piece of glass tube, is now cracked near the bottom, and consequently the vacuum has been destroyed, but that such a vacuum once existed is conclusively proven by the deep concave depressions in the top of the chamber, made by the pressure of the external air when the lamp was sealed off, and before the glass had set. The leading-in wires of this particular lamp are of copper, but both platinum and iron are used in other specimens. An examination of the filament of this lamp under a magnifying glass, shows plainly that it is made of carbonized woody fibre of endogenous growth; undoubtedly bamboo. The filament is $1\frac{1}{16}$ inch long and about $\frac{8}{1000}$ of an inch in thickness, and is elastic and flexible. The ends of the supporting wires are bent into little spirals into which the ends of the carbon filament are thrust, and the joint is secured by a carbonaceous cement; Dixon's stove polish having been employed, according to the statement of the maker. Other lamps examined by the writer, have much thinner leading-in wires, and in some instances the joint has been secured by electroplating it with copper in a bath. Not one essential feature of the modern incandescent lamp is wanting in these examples. There is the filament of carbon, elastic and flexible, first formed and then carbonized, of high resistance and secured to metallic conductors of platinum sealed into the walls of a highly exhausted glass chamber. The familiar smoky discoloration on the interior of the glass, due to the continuous burning of the carbon at high incandescence, is plainly visible in the illustration, proving that the lamp has been put to its intended use, and that the vacuum was, at all events, sufficiently high for that purpose.

Finding the "meat-saw" form of burner liable to give way by the fracture of the filament near its points of attachment, owing to the effects of repeated expansion and contraction, Goebel sought to improve it by the substitution of a spiral or corkscrew shaped carbon, in which he was measurably successful, although but few of these were made, as he soon found that equally good results could be obtained with less trouble by making the carbon in the familiar arch-shape, or as the inventor called it, of the "hair-pin" pattern.

These lamps were exhausted by the process of sealing them, after the carbons and leading-in wires were in place, to the upper end of a glass tube about three feet long, which, being held in an inverted position and filled with mercury, was again inverted while at the same time the mouth of the tube was immersed in a bowl of mercury. The mercury at once descended below the contracted portion of the tube at the top of the lamp, which portion was then softened in a blowpipe flame and sealed off in the ordinary way now practiced.



Henry Goebel

Long before the removal of Goebel from the shop so long occupied by him, which was in 1874, he had been accustomed to set up two or three of these lamps on the show-case and exhibit them to the public, and a considerable number of persons have been found who have a distinct recollection of having seen them burning. One of the lamps is remembered as having been placed in front of the dial of a clock, and arranged with a circuit-closer attached to the mechanism, so as to be automatically lighted during the time of the striking each hour. But the most important public exhibition and use of these lamps, and that which appears to have been seen and remembered by the largest number of persons, has already been referred to in connection with the astronomical telescope. This telescope was quite a large one, having an aperture of some 12 inches, and being 15 or 20 feet in length. It was mounted upon a four-wheeled wagon constructed expressly for the purpose, upon which was carried, besides the telescope, two wooden chests capable of containing 30 large battery cells each, for operating the incandescent lamps. Two or three lamps were lighted simultaneously when the batteries were fresh, and a single lamp could be kept in operation half an hour or more at a time, or until the battery was exhausted. These street exhibitions were given at frequent intervals for two or three years prior to 1860 and also during that year.

With a view of taking advantage of the excitement which at that time filled the public mind with reference to Edison's discoveries, a company was organized in New York, which attempted early in the year 1881, to manufacture and install electric lamps. The person in immediate charge of the lamp manufacture, who was supposed to have gained his knowledge in Edison's laboratory appears to have met with very poor success in his earlier efforts, and thus it happened that a person connected with the company, chancing to hear some rumor of Goebel's work, sent an expert assistant to investigate the matter, who was surprised not a little to find that this obscure artisan was not only an expert manufacturer of carbon filaments, as well as of complete lamps, but that he had quite a stock of these articles in his possession, together with a complete outfit of mercury pumps and other necessary appliances for carrying on the business. As a result of this discovery, Goebel was taken into the service of the company, and at once commenced turning out successful lamps with carbons of unusually excellent quality, and continued to do so until the company fell into financial difficulties and suspended active operations, an event which occurred within a very short time. In view of the very considerable number of persons to whom these facts must at the time have been more or less known, it is certainly very singular that they should have attracted so little attention among those who might naturally be supposed to feel the most interest in the matter.

The fact that Mr. Goebel himself has not pressed his claims to public recognition as an inventor of the incandescent lamp, is, in view of all the circumstances of the case, not difficult of explanation. Although so long resident in the United States, his associations have been mainly confined to the somewhat obscure neighborhood in which has always lived, and to people from his own country. He speaks and understands the English language with some difficulty, and can scarcely read it at all. He never made, so far as it appears, any secret of his methods of constructing and operating the lamps, but as he had constructed his batteries for operating them with his own hands, and had paid the cost of their maintenance out of his own pocket, doubtless no one knew better than he, that so long as it was dependent upon any such source of electricity, the incandescent lamp, interesting and beautiful as it was as a scientific demonstration, was, nevertheless, wholly incapable of extended commercial use. Considering Goebel's circumstances and surroundings, it is perhaps not a matter of surprise that the knowledge of the applicability of the dynamo to this purpose, which only began to attract public attention in the early part of 1880, did not reach him, and that such knowledge should first have come to him through his employment by the lamp company in 1881. He might, it is true, have applied for a patent at that time, but in view of his long continued and repeated use of the invention in public, more than twenty years before, it is, to say the least, a matter of some doubt whether a valid patent could have been granted to him.

A few words respecting the personal characteristics of the man who forms the central figure in this somewhat dramatic episode in the history of the progress of electrical invention, may not be out of place. Although seventy-four years of age, Mr. Goebel's figure is as erect, his eye as bright, and his hand as steady, as a man's in the prime of life. Few can excel him, even at his age, in delicacy, skill and accuracy of touch, in the finer processes of handicraft. Of an unassuming, cheerful and kindly nature, nothing delights him more than to converse upon topics relating to his favorite pursuits of optics and electricity, or to relate with a humorous twinkle of the eye, some of the scientific practical jokes that in younger days he was wont to play upon his unscientific and unsuspecting associates. After a long, industrious and well-spent life, he is passing his declining years in comfort and contentment, in a quiet country village within half a day's journey from the metropolis. The portrait which accompanies this article was taken quite recently, and is a most excellent likeness. The face is that of an observer and student of nature; of a thinker, an inventor, and a mechanician; the very man of all others who might have been expected to have originated that which it has been proven, so far as abundant corroborative testimony can prove, he did in fact originate—the practical electric incandescent lamp.

NEW YORK'S ELECTRICAL SUBWAYS.—IV.

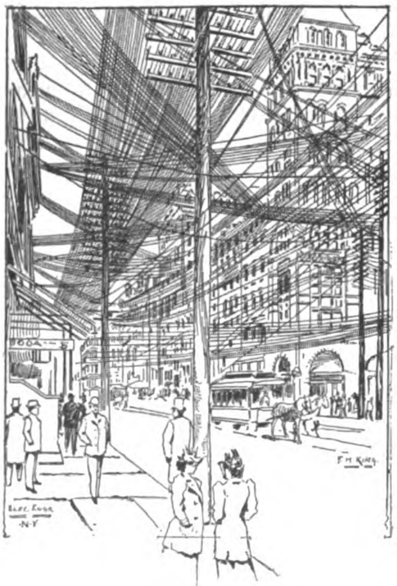
BY

Wm. Maver Jr.

(Concluded.)

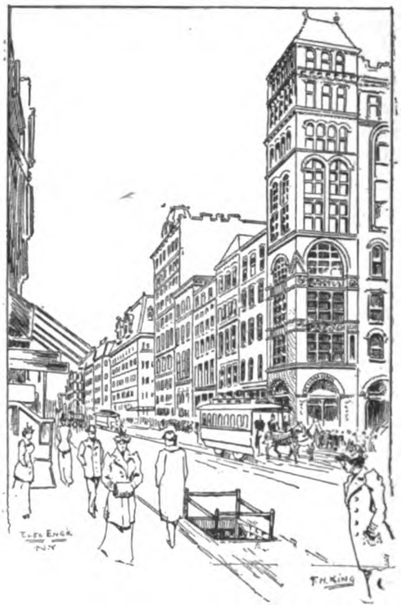
XIII.—COMPARATIVE COST OF MAINTENANCE AND ADVANTAGES OF WIRES—UNDERGROUND WIRES VERSUS WIRES OVERHEAD, IN CITIES.

The question of comparative cost of maintenance of underground wires *vs.* overhead wires, in cities, is obviously a very important one.



Broadway, New York, Before the Removal of Overhead Wires.

The more common items of maintenance of overhead wires in cities are the removing of foreign substances, kite tails, etc., from the wires; trimming foliage; removing ordinary crosses and grounds; removing poles and wires out of the way of scaffolding for new buildings; repairing and replacing cross-arms, insulators, etc.; repairing wholesale damage to lines caused by severe wind-storms, sleet and snow-storms, etc. It is known that the cost of repairing miles of overhead wires after severe storms has frequently amounted to a virtual renewal of the pole line.



Broadway New York, After the Removal of Overhead Wires.

To the cost of those items may be added incidental loss of revenue due to imperfect working, or, as often happens, entire suspension of business during extensive repairs. This applies generally to telegraph, telephone and electric light wires, but, in the case of the latter, there may be added losses due to damage to armatures, etc., caused by breaks, crosses, grounds and lightning. Also may be added, in the case of the latter, the payment of damages on account of injuries and fatalities by direct or indirect contact with overhead electric light wires. In the case of telegraph and telephone service the losses occasioned by fires as a consequence of the contact of overhead telephone or telegraph wires with electric light wires cannot be neglected. Experience has abundantly shown that none of the foregoing items of expense or causes of losses, excepting that of an occasional "ground" or "burn out," has to be considered in the case of properly made and properly laid underground wires.

Perhaps, however, the most important single feature of overhead maintenance in cities as compared with underground maintenance is that of periodical renewal of the pole line. The average life of an overhead wire system, including poles, etc., in cities may be placed at ten years. From present appearances the life of the underground cables in the New York subways will be as long as that of the lead covering. As already mentioned that shows no sign of deterioration.

Apart from the cost of rentals, or the maintenance, of subways, therefore, the cost of maintenance of a well-established underground wire system must clearly be much below that of an overhead system of equal extent. As an instance may be cited the case of an electric light company having no overhead circuits and operating over 25 miles of underground cable, in the service of which, for over a year, there has not been, so far as the underground conductors are concerned, any occasion for a single "shut down," and during which time not a penny has been expended for "patrol" or repairs. Taking the average of several hundred miles of underground electric light wires in this and other cities of which I have knowledge, and including the expenses of testing circuits, repairing an occasional bad joint, or burn out, and of replacing an occasional defective portion of cable, I believe it is a liberal estimate to place the average cost of maintenance of well constructed and well managed electric light underground cables at from five to eight dollars per mile, per annum. Of course, the full economic advantage of underground service cannot be realized so long as any considerable part of the circuits remains overhead, for, in that case, delays and damage incidental to overhead wire service will continue.

The average of maintenance of overhead wires in cities may be placed at about 18 dollars per annum per mile. This is exclusive of rental for roof privileges, etc., and does not include outlay for periodical renewals of the pole line, nor the payment of claims for injuries or fatalities due to whatever cause.

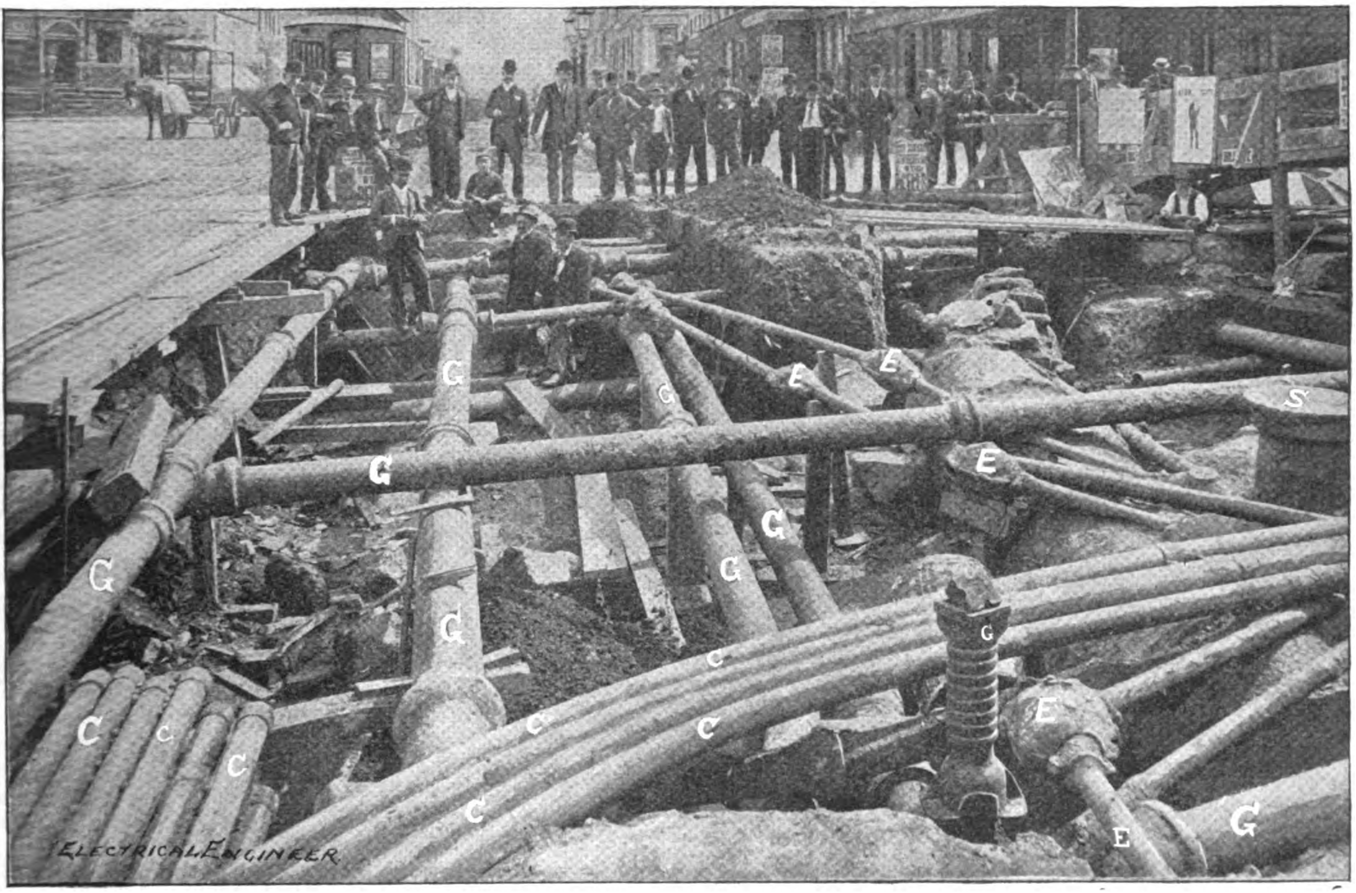
In the matter of public safety the advantage is, of course, all in favor of underground wires. Apropos of this it may be noted that during the year 1888 there were according to the Board of Health, five lives lost by contact with electric light wires, in New York City. There has not thus far been one fatality due to contact with electric light wires in the New York electrical subways since they were built.

The disadvantages of underground service are, it would seem, almost entirely economic, consisting as they do, mainly, of the first cost of conductors, and the cost of construction and maintenance of subways or rentals therefor, and the greater difficulties in the way of reaching districts more or less remote from the line of the subways.

As to reliability of service, it is now generally admitted that the advantage is altogether with the underground conductors.

XIV.—THE DIFFICULTIES OF SUBWAY CONSTRUCTION.

Some idea of the outlay necessary for subway work, of the crowded construction of the streets underground and of the engineering difficulties encountered in the construction of the electrical subways in this city may be gathered from the illustration (Fig. 21) showing the excavations made at the corner of Broadway and Fourteenth street, preparatory to laying the conduit for the cable of the Broadway Surface Railway. The pipes marked G G are water and gas mains; S S are sewer pipes and sewer manholes; E E are Edison conduits; C C are the wrought iron pipes of the electrical subways. The flexibility and utility of the wrought iron pipes for this purpose is shown in the illustration where they are curved to turn from Fourteenth street into Broadway; the pipes having been bent to the proper curvature by the workmen as the construction proceeded. In many cases, as obstructions have been met, it has been necessary to bend these pipes twice within their own length, care being taken, of course, that the bends shall not be so sharp or frequent between manholes as to interfere with the drawing in and out of cables. The cement in which the pipes are laid, the protecting planking, etc., had, it will be observed, been removed before the photograph from which the illustration is made, was taken. It may be added that there are other streets in this city in which pipes, sewers, etc., are even more crowded than is the case at the point illustrated.



EXCAVATION EXPOSING ELECTRIC, GAS, WATER AND SEWER PIPES, 14TH STREET AND BROADWAY, NEW YORK.

XV.—WHAT THE SUBWAYS ACCOMPLISH.

It may not be generally known that the New York electrical subways (apart from those of the Edison system) were designed to meet the following general requirements, namely, that they should afford a ready means of drawing conductors in and out of the ducts as desired; that they should afford easy access for additions, alterations or repairs to conductors, and should provide facilities for the distribution of current, but aside from which it was designed that they should serve only as a mechanical protection for the conductors placed therein, it being deemed impracticable to attempt to construct and maintain subways intended for general use which should serve also as insulators for the conductors. The question of electrically insulating the conductors was therefore left entirely with the users of the subways.

The successful operation of these subways, and of the conductors within them, during the past five years, and at the present time, has shown that they have well fulfilled the requirements laid down, and further, has, in view of the peculiarly crowded conditions of many of the New York streets underground—an illustration of which has been given—the liability to flooding from various causes and the great strains to which the conduits would be subjected by traffic, street excavations, etc., demonstrated, I think, that the material employed and the general construction and design were the best that could have been selected and devised for the purpose.

From an æsthetic point of view, the gain to a city by the placing of electric wires underground may be judged by a comparison of the accompanying illustrations showing the appearance of a portion of Broadway, New York City, near THE ELECTRICAL ENGINEER offices, "before and after."

LAMINATED OR DIVIDED IRON AND OTHER METALLIC MASSES IN ELECTROMAGNETIC APPARATUS.—IV.

BY

Thos D Lockwood

Leon Foucault.

The year 1846 shows us a British patent granted to Edward A. King (a communication, probably from his associate Starr), April 30, No. 11,188, for "Improvements in the Production of Magnetic Electricity," the fourth section of which relates to "A method of preventing the formation of neutralizing currents in the brass or other metallic plates forming the wheel which carries the armatures." A saw cut is made from the edge to the hole through which the armature passes.

In this year, also, Joule has a paper (*Phil. Mag.*, series 3, vol. xxx, pp. 76,225), on the "Effects of Magnetism upon the Dimensions of Iron and Steel Bars," describing experiments, in which he says he employed "fine wires, both of iron and steel, bundles of very fine iron wires, chains composed of copper and iron links, etc."

A patent was taken out in England, by William H. Hatcher, on March 23, 1847, No. 11634, for an improvement in "Electric Telegraphs and Time Keepers," which describes an electromagnet having an iron core built up of laminations. The core is V-shaped, and is made of soft iron, or preferably of "*a series of thin plates of iron placed closely side by side.*"

Daniel Davis, an electrical instrument maker, of Boston, wrote prior to 1848 a most instructive little work entitled "A Manual of Magnetism." It is even now a very readable book. The second edition was published in 1848. Magneto electric induction is discussed in it most intelligently (pp. 264–306), and (pp. 287–291) the action of bundled iron wires when used for induction coil cores is dealt with; as is also the operation of metallic screen tubes, which can be slipped over the core to decrease the spark and shock.

The operation of the bundled core is rightly ascribed to its breaking up of the eddy current circuit, and it is pointed out that the tube, if split, no longer acts as a screen, and also that sawing a solid iron core longitudinally to its centre, in the direction of division, improves its effects.

Isaac L. Pulvermacher patented in England, Dec. 15, 1849, No. 12899, improvements in about all known kinds of electrical apparatus, among which was a magneto machine which he says may be constructed of "flat grooved plates."

The next instance we find is in a British patent, granted to Werner Siemens, April 23, 1850, No. 13062, for "Improvements in Electric Telegraphs," the first of said improvements relating to electro magnets, and consisting in the use, instead of solid iron cores, of iron tubes cut open longitudinally, which, however, have poles formed of large masses of iron having considerable surface.

In a British patent granted to John F. Kingston, Dec. 22, 1852, No. 1134, a variation appears. This patent is for "Obtaining Motive Power by Electromagnets," and it shows electromagnets, the cores of which each consist of several plates of soft iron or nickel. The energizing wire however is wound round each of the individual plates composing the core.

In a "Treatise on Electricity in Theory and Practice," by Aug. de La Rive, (Vol. i, London, 1853), Chap. 5, comprising pp. 347—440 is devoted exclusively to the subject of electro-dynamic induction, which subject is most elegantly, and considering the time, exhaustively treated. On page 81, induction coil cores are considered; the superior advantages of cores made up of insulated soft iron bars are explained, and the principal reason for their use given is, that when they are used, eddy currents cannot circulate. The action of hollow brass or copper cylinders over the core is also discussed.

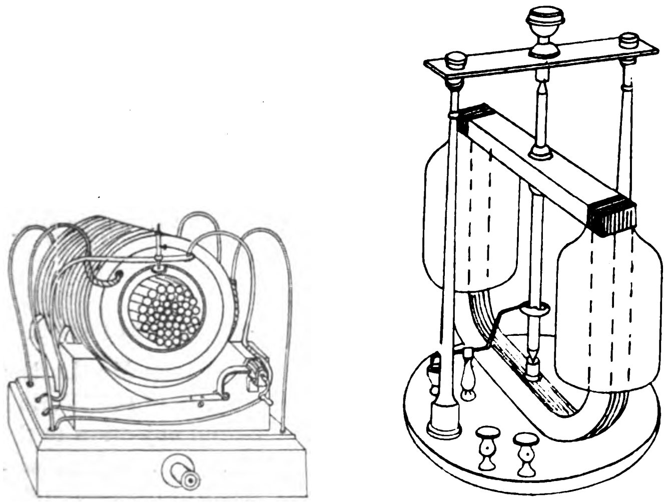
In the same work (p. 388) Bonijol's coil is described, and illustrated and, referring to Fig. 2, it is stated that "the core is not a single cylinder but a bundle of small cylinders covered with an insulating varnish of wax." Considerable space is given in the same work to the researches of M. Dove. The account given of these, is of the highest interest and includes an elaborate discussion on the influence of magnetic masses in bobbins. It well repays a close study and examination, and the action of iron wires—and thick and thin tubes, is fully considered. The reason of these advantages is also analyzed, and the existence of adverse eddy currents proved experimentally.

In 1855, the London, Edinburgh and Dublin *Philosophical Magazine* (Vol. x, 4th series pp. 5 and 6) has a long pape by Poggendorff on "Induction Coils, their Construction and Arrangement," which everyone interested in the subject should read through. It foreshadows quite a number of recent inventions in inductive distribution. In it, together with many other things, Poggendorff shows that in 1855, divided magnetic cores for induction coils were a matter of course; and also that it was not unusual to insulate the divisions. He says with regard to his subtitle—Soft Iron Cores: "Usually this is formed of pretty thick wires *or we may almost say small bars* held together by a common cap, but yet separated from each other by some insulating medium. I have employed such a collection of bars but oftener I used cores of much thinner wire * * *. I found it unnecessary to cover the wires with a varnish, partly because the stratum of protoxide which forms on the surface when heated, is comparatively a bad conductor; partly because the irregularity of the spaces between the wires, none of which remain straight, is more than sufficient to destroy the pernicious continuity in the direction of the periphery of the core."

A British patent was granted on Dec. 4, 1856, to Cromwell F. Varley, No. 3059, which was remarkable for its many sided prevision. It comprised an induction coil having a central core, and an outside casing, both of iron, both finely divided, and joined together in the direction of magnetic continuity to form a magnetic circuit. The central core in the principal form shown, is made up of iron wires which extend out from the ends of the coil, and are lapped backwardly over the outside so as to encase the whole coil practically with iron wire.

A similar construction for induction coil cores was also in the following year advocated in a patent issued in England to our old friend of electric belt fame, Isaac L. Pulvermacher, No. 2411, of Sept. 17, 1857; and laminations of the coil cores of magneto-machines are suggested in the French patent of Berlioz No. 21590 of July 25, 1858.

1859 presents but one instance for our record, but that one is worthy of remark. It is an induction coil with a rotary armature arranged to operate the break. Fig. 3 shows the construction of this coil, which was made by Mr. W. T. Henley, and presented to Henry M. Noad, who describes it. ("Manual of Electricity," Vol. II., pp. 721–722). The machine was in the form of an electromagnet with two spools, and a **U**-shaped core made of a series of **U**-shaped bars of soft iron and bolted together. Over this was first wound a coarse wire to form the primary helix, and then a long winding of fine wire for the secondary. Noad observes toward the end of his description, that "when the ends of the secondary are disunited, the sparks from the primary are large and brilliant; when united they are small and faint." He also in a foot-note gives some brief historical notes referring to the work of Sturgeon, Bachhoffner, Magnus, and Dove in investigating divided cores, and mentions that the work of Magnus and Dove is recorded in Peschel's "Elements of Physics;" (Vol. III., p. 237). Fleming refers to Henley's work in the second volume of his "Alternate Current Transformer," pp. 33–35.



FIGS. 2 AND 3.

A British patent to Chas. W. Harrison, No. 2116 of Sept. 1, 1860, describes an induction coil. The cores described are cylindrical, of iron, and formed either of bundles of wires, or of slotted tubes.

At this point we may take our leave of induction coil cores which are provided merely with unmodified cores made up of fine iron wires, since other improvers—Ruhmkorff, 1851; Stohrer, 1854; Hearder, 1857; Ritchie, 1857, and Gassiot, 1858, did not especially concern themselves with cores. Hearder, however, according to Fleming, says that he improved the iron core by using smaller iron wires than Ruhmkorff.

We may here note that the function of such cores is stated with striking terseness by Prof. S. P. Thompson in his "Elementary Lessons in Electricity and Magnetism," 1st Ed., London, 1882, p. 364, where he says: "The central iron core is for the purpose of increasing by its great coefficient of magnetic induction the number of lines of force that pass through the coils; it is usually made of a bundle of fine wires, to avoid the induction currents, which if it were a solid bar, would be set circulating in it, and which would retard its rapidity of magnetization and demagnetization."

In 1865, Henry Wilde patented in England a magneto-machine having a cast iron armature core having a slot extending three-fourths of its length (British Patent, No. 2762, Oct. 26, 1865).

The Gramme machine which, as every one knows, had a ring armature core composed of an iron wire coiled into a thick hank, was patented in France, No. 87938, Nov. 22, 1869; and in England on June 9, 1870, No. 1668. The latter specification states that the soft iron which is to be magnetized, is given the "form of a solid or hollow ring, cylinder, or other suitable endless shape, constructed of a bundle of iron wires." The Gramme machine has been described in nearly every text book or electro-technical periodical published between the above dates and 1882, and is such a familiar apparatus that no further reference to it is necessary.

In 1870, Sir Wm. Thomson took out a British patent, No. 3069, Nov. 23, for "Improvements in Electric Telegraphs, etc." Speaking of electric engines, the patentee says:—"I diminish the inductive action * * * * and increase the maximum speed and efficiency, by taking advantage of another principle discovered by Faraday, and dividing the soft iron core into parts separated from one another by thin layers of varnish or other non-conductor, in surfaces cutting across the lines of flow of the currents which are induced in the iron when this improvement is not made. One way of executing this improvement is to make the core altogether, or in part, of varnished soft iron wire which, however, has the disadvantage of leaving considerable interstices not occupied by iron. I prefer a smaller number of pieces fitting approximately to one another." This is a remarkable statement. It is, of course, inaccurate in ascribing the principle of division to Faraday; but it is clear that Sir William appreciated the importance of dividing the iron core, and it is curious to note the close resemblance between his language and that of the present day concerning the direction of division.

In 1871, two patents were granted in England to S. A. Varley, Nos. 131, on January 18, and 1150 on April 29, which both show for field magnets a number of magnetized bars piled one upon another, and held apart by being mounted in holes drilled in metal supporting plates.

In 1871, also, we once more hear from Joule, who read a paper before the Manchester Literary and Philosophical Society, March 21, 1871, on "Examples of the Performance of Electro-Magnetic Engines." He concludes by stating that "the actual duty is less than the theoretic; which is owing partly to the pulsatory nature of the current, and partly also to induced currents giving out heat in the substance of the iron cores of the electromagnets; although these last were obviated as far as possible by using annealed tubes with slits down their sides." It should be stated that all of the papers of Joule, to which reference has been made, are easily accessible, since they have been collected and published by the Physical Society of London in two volumes, dated 1884 and 1887 respectively.

VOL. XV. NEW YORK, JANUARY 25, 1893. NO. 247.

AT THE ELEVENTH HOUR.

SINCE the final decision of the Circuit Court of Appeals affirming the validity of the Edison incandescent lamp patent, one after another of the large lamp-manufacturing concerns have been compelled by due process of law to close their doors and dismiss their employés. On Monday, the turn of the Beacon Company, of Boston came, the General Electric Company's counsel having made application to Judge Colt for an injunction. It had been supposed that the granting of this injunction would be a mere matter of course, but when the case came to be called, the audience in the court-room were treated to a genuine surprise, not to say a sensation. The counsel for the Beacon company, armed with a formidable pile of affidavits, proceeded to attack the Edison patent in its most vital point. He produced a number of incandescent lamps, in all material respects the precise counterpart of the Edison lamp, containing a thin filament of carbonized bamboo, with its metallic terminals sealed into an exhausted glass globe; and then proceeded to read from one affidavit after another a great mass of testimony going to show that these self-same lamps had been made at least twenty years before the Edison lamp was ever heard of, by an obscure artisan in one of the humblest neighborhoods of New York and had been publicly exhibited and used by him year after year, within the sight and knowledge of perhaps thousands of people. At first sight, such defence as this, brought forward at this late day, seems absolutely incredible, but the more the evidence is examined, the more does one become convinced, in spite of himself, that the story, at least in its essential particulars, is probably true. Abstracts of the more important of these affidavits are given in our report of the proceedings in another column, and the connected history of the invention, as confirmed by the affidavits, and in part verified from independent sources, is given at length in an illustrated article, hastily prepared for us, by Mr. F. L. Pope.

What will be the ultimate effect of this amazing disclosure upon the Edison patent? Must this patent, too, be compelled to succumb to the adverse fate which has heretofore befallen the patents of Siemens, Gramme, Brush, Gaulard & Gibbs, Sawyer & Man, Weston, and other pioneer inventors in applied electricity? There can be but one answer; if the courts believe the sworn statements of the thirty or more witnesses, who more or less positively identify and fix the date of the Goebel lamp and its public use prior to the breaking out of the rebellion in 1861, then it most certainly seems as if the Edison patent was doomed. Perhaps there is no better off-hand test of the question of anticipation than to inquire whether the alleged anticipating structure, if constructed to-day, would be an infringement of the claims of the patent. In this aspect of the case, the resemblance in the present instant is too clear to require argument. The Goebel lamps are far more nearly identical with the commercial lamp of to-day than they are with the structure described in the Edison patent.

The Court has not granted any injunction as we go to press, but is still in session. In the meantime, by dint of no small effort night and day, and by the unstinted use of the long distance telephone, we are able to present our readers with that which is, whatever its merits and whatever its outcome, one of the most remarkable stories of invention we are acquainted with. Our narrative, and the report of the proceedings in Boston, tell the whole story thus brought to light.

THE WORLD'S FAIR ELECTRICAL FOUNTAINS.

WE publish on another page a letter from Mr. Luther Stieringer, the consulting electrical engineer of the World's Fair, in which he makes a very natural objection to the gross injustice done him by *The Electrical World* in issuing what purport to be views of the electrical fountains that he has designed for the World's Fair, and which appear entirely without his sanction or approval. We also have a little duty to discharge in this connection, in mentioning a few facts. All the drawings published by the *Electrical World were first submitted to us* by the artist who made them, and were accepted, *subject to Mr. Stieringer's approval,* there being some doubt in our minds as to their accuracy. They lay in our office for about a week. On Mr. Stieringer's return from Chicago, they were at once shown him, when he objected to them strongly, and requested us not to use them. The artist was also informed by him that they would not do. He was asked to "turn them to the wall" and to prepare others. They were, however, taken to the *Electrical World,* and peddled there. It seems to us that while artistic imagination may know no bounds, newspaper decency should know some; and that Mr. Stieringer's confidence and reputation have been shamefully abused. As to the quality of the work in these sketches, on which our contemporary spread itself so recklessly, we may remark that the middle fountain of the three is *not* to have any electric light of its own at all, and that the details of the ironwork for the two electric fountains proper are still being determined by the designer and the iron manufacturer!

SOME MECHANICAL AND ELECTRICAL ANALOGIES.

BY

Frederick Bedell & Albert C. Crehore.

No phenomena are so readily comprehended as those which may be compared directly with facts that are familiar, and no reasoning is so quickly grasped as reasoning "by analogy." The analogies between certain mechanical and electrical relations are so striking that when either relations are understood the others follow, and from the laws of mechanics we can readily write those of electricity. The process is a reversible one and the electrician can with equal ease step over into the realms of dynamics. To enable one to reason accurately in this manner and to reach definite results with absolute certainty, it is necessary to give with exactness the fundamental relations of mechanics and electricity.

The following tables are, therefore, given showing the analogies between linear motion, motion of rotation and the electric current. Starting a current of electricity in a circuit is analagous to imparting motion to a body and requires an impressed force. This force must overcome the resistance (electrical resistance corresponding to that of friction) and the inertia of the mass or current. In the case of the electric current this inertia is called "self-induction." A revolving fly-wheel may well represent the flow of electricity, its velocity corresponding to the current, its moment of inertia to the co-efficient of self-induction and the friction to ohmic resistance. A study of the tables will make these analogies more clear.

TABLE I.—LINEAR MOTION.	TABLE II.—ROTARY MOTION.	TABLE III.—ELECTRIC CURRENT.
Notation.	*Notation.*	*Notation.*
1. Time = t.	1. Time = t.	1. Time = t.
2 Distance = s.	2. Angle = ϕ.	2. Quantity = q.
3. Linear velocity = $v = \frac{d\,s}{d\,t}$. $d\,s = v\,d\,t$.	3. Angular velocity = $\omega = \frac{d\,\phi}{d\,t}$. $d\,\phi = \omega\,d\,t$.	3. Current = $i = \frac{d\,q}{d\,t}$. $d\,q = i\,d\,t$.
4. Linear acceleration = $a = \frac{d\,v}{d\,t} = \frac{d^2\,s}{d\,t^2}$.	4. Angular acceleration = $\alpha = \frac{d\,\omega}{d\,t} = \frac{d^2\,\phi}{d\,t^2}$.	4. Current acceleration = $\beta = \frac{d\,i}{d\,t}$.
5. Mass = M.	5. Moment of inertia = I.	5. Coefficient of self-induction = L.
6. Momentum = $M\,v$.	6. Angular momentum = $I\,\omega$.	6. Electromagnetic momentum = $L\,i$.
Frictional Resistance.	*Frictional Resistance.*	*Ohmic Resistance.*
7. Frictional resistance = R.	7. Frictional resistance = R.	7. Ohmic resistance = R.
8. Force to overcome resistance = $F_R = R\,v$.	8. Torque to overcome resistance = $T_R = R\,\omega$.	8. E. M. F. to overcome resistance = $e_R = R\,i$.
9 Energy expended in overcoming resistance in the time $d\,t = d\,W_R = F_R\,d\,s = R\,v^2\,d\,t$.	9. Energy expended in overcoming resistance in the time $d\,t = d\,W_R = T_R\,d\,\phi = R\,\omega^2\,d\,t$.	9. Energy expended in overcoming resistance in the time $d\,t = d\,W_R = e_R\,d\,q = R\,i^2\,d\,t$.
Inertia.	*Inertia.*	*Self-Induction.*
10. Force to overcome inertia = $F^1 = M\,a = M\,\frac{d\,v}{d\,t}$.	10. Torque to overcome inertia = $T^1 = I\,\alpha = I\,\frac{d\,\omega}{d\,t}$.	10. E. M. F. to overcome self-induction $\Big\} = e^1 = L\,\beta = L\,\frac{d\,i}{d\,t}$.
11. Kinetic energy acquired in the time $d\,t \Big\} = d\,W^1 = F^1 ds = Mv\frac{d\,v}{d\,t}d\,t$	11. Kinetic energy acquired in the time $d\,t \Big\} = d\,W^1 = T^1 d\,\phi = I\omega\frac{d\,\omega}{d\,t}d\,t$	11. Energy acquired by the magnetic field in the time $d\,t = d\,W^1 = e^1\,d\,q = L\,i\,\frac{d\,i}{d\,t}\,d\,t$.
12. Kinetic energy = $W^1 = \int_0^v M\,v\,\frac{d\,v}{d\,t}\,d\,t = \frac{1}{2}\,M\,v^2$.	12. Kinetic energy = $W^1 = \int_0^\omega I\,\omega\,\frac{d\,\omega}{d\,t}\,d\,t = \frac{1}{2}\,I\,\omega^2$.	12. Energy of magnetic field = $W^1 = \int_0^i L\,i\,\frac{d\,i}{d\,t}\,d\,t = \frac{1}{2}\,L\,i^2$
Inertia plus Resistance.	*Inertia plus Resistance.*	*Resistance plus Self-Induction.*
13. Total force applied = $F = F_R + F^1 = R\,v + M\frac{d\,v}{d\,t}$	13. Total torque applied = $T = T_R + T^1 = R\,\omega + I\,\frac{d\,\omega}{d\,t}$	13. Total E. M. F. applied = $e = e_R + e^1 = R\,i + L\,\frac{d\,i}{d\,t}$
14. Total energy supplied in the time $d\,t = d\,W = d\,W_R + d\,W^1$; or, $F\,d\,s = F_R\,d\,s + F^1\,d\,s$; or, $F\,v\,d\,t = R\,v^2\,d\,t + M\,v\,\frac{d\,v}{d\,t}\,d\,t$.	14. Total energy supplied in the time $d\,t = d\,W = d\,W_R + d\,W^1$; or, $T\,d\,\phi = T_R\,d\,\phi + T^1\,d\,\phi$; or, $T\,\omega\,d\,t = R\,\omega^2\,d\,t + I\,\omega\,\frac{d\,\omega}{d\,t}\,d\,t$.	14. Total energy supplied in the time $d\,t = d\,W = d\,W_R + d\,W^1$; or, $e\,d\,q = e_R\,d\,q + e^1\,d\,q$; or, $e\,i\,d\,t = R\,i^2\,d\,t + L\,i\,\frac{d\,i}{d\,t}\,d\,t$.

It is to be noted that the fly-wheel or moving mass, in slowing down, gives back its kinetic energy and the wheel is carried on, after the impressed force is removed, until this is entirely consumed in overcoming friction. Similarly, when the current diminishes upon the removal of the impressed electromotive force, the energy stored in the magnetic field is restored to the circuit and the current keeps flowing until the energy is entirely used up in overcoming the ohmic resistance.

These analogies cannot be considered as rigorous proof. The truth of the relations here given for the electric current has been fully established and may be found in the introductory chapter to our work on "Alternating Currents." Other striking analogies will suggest themselves, but space will not permit calling attention to any but the most fundamental ones given above.

PHYSICAL LABORATORY, CORNELL UNIVERSITY.

INSULATED ELECTRIC CONDUCTORS.—XVII.

BY

James Bowstead Williams M.I.E.

Paraffin.—This is a useful ingredient both for insulating and protecting paints. Its function is to impart elasticity, or to assist in doing so, and also durability to paints; but paints containing it dry more slowly than the same compositions *minus* the paraffin do. To use it properly, first melt the other solids and then add the wax, but at a temperature just sufficient to cause it to unite. The combination of solids is then ready to be dissolved in suitable solvents. Paraffin does not decompose as readily by heat when in *compounds* as it does when heated separately; and this is an important feature when compounds containing it have to be boiled for some hours in oil in order to form a perfect paint. If used in too large proportions it will cause "curdling" of paint during the preparation thereof. Solvents, as a rule, dissolve but a small quantity of it, and the majority of the published "receipts" for its use, when in solution for waterproofing, etc., are worthless. Paraffin unites with the most important substances which can be used for paint, but it should rarely exceed more than about five per cent. of the entire weight of the solids.

Beeswax.—This is used in practically the same way and for the same purposes as paraffin, but larger proportions may be used. It does not affect the drying of paints to such a degree as paraffin; it will stand higher temperatures, and impart a greater degree of toughness to the mass than the latter. The best way to use it is to melt with other solids, but it can be added, while in solution, to other solutions, if desired.

India Rubber.—This is used to render paints flexible, or elastic, according to the proportions used. When thus used it should be cut into fine pieces, dissolved in linseed oil, which requires about five hours at a boiling heat, and then added to the other solutions which have been made with a good rubber solvent. Of all the solvents bisulphide of carbon is the best, for it leaves the rubber, after evaporation, in its *natural* state, which is not the case with the solvents commonly used. Further, the bisulphide is a good solvent for most of the resins, asphalts and waxes, and it has this advantage over other solvents in that it can be recovered with but little loss after it has served its purpose.

The bisulphide for rubber paints should be purified. Rubber can be dissolved in rosin, by using a high temperature for five hours, and then dissolved in oil, turpentine, etc., but such paints remain soft for weeks afterward.

Most of the "rubber paints" on sale do not contain a particle of rubber, the elasticity which some of them possess being due to the oxidized oil and oxides of zinc and lead which they contain.

All rubber *paints* dry slowly, but rubber varnishes, *i. e.*, rubber in a volatile solvent, dry quickly.

Glass, silica, and asbestos may often be used with advantage if they are ground to an impalpable powder and thoroughly incorporated in the paints and the braids are not too close or tight.

As before stated, pure linseed oil is the best oil for paints, but be certain that it *is* pure before using. Factitious oils which contain sperm oil and the cheaper seed oils, etc., resemble the genuine oil so closely, even in color and specific gravity, that it is often a difficult matter to know when one does have the genuine.

For *protecting* paints heavy petroleum, alone or with a volatile liquid, is the best solvent.

The oleo resins, gum turpentine and Venice turpentine, can be used to make paints and varnishes more flexible, when first applied, but this effect does not continue owing to the constant changes of these substances by oxidization and evaporation.

The uses to which insulating paints and varnishes, apart from that of saturating the fibrous coverings of wires, are many and various. Cases are continually occurring in practice where additional insulation of wires is required, particularly when used in damp localities and where they are fastened to small glass and porcelain insulators; where parts of apparatus need extra insulation, as well as protection from air and light; where the stems of insulators need coating, and also the ends of some forms of insulated wires. In such cases there is perhaps nothing better than properly selected paints or varnishes to fulfill the required conditions.

In the next article the manufacture of insulated conductors will be considered.

ELECTRIC RAILWAY DEPARTMENT.

ELECTRIC RAILWAY AND LIGHTING STATIONS.

BY

C. A. Cooley

There seems to be no settled plan of construction and arrangement of electric lighting and power stations. During the first few years of electrical development, when its introduction was considered more or less as an experiment commercially, the matter of first cost entered largely into the calculations of its promoters. Many plants were built with the smallest possible outlay, and advantage was taken of existing and immediately convenient locations. But now the industry has passed the experimental period, and fully demonstrated its ability as an earner of dividends, and is attracting millions of capital seeking investment. Many of the electric generating stations being built to-day are marvels of solidity, and have an air of stability and permanence which impresses one as do the massive banking and business blocks of our large cities.

The problem before the electrical engineer of to-day is not how to make the smallest amount of money cover the most ground, but, with almost unlimited resources of capital, material and generating machinery, how to combine all of these elements to form a beautful and massive whole. The question of future needs and extensions should enter into the calculations as much as ever, and the engineer will save himself much trouble, and his company many dollars, who can so see and plan for the future as not to tie up and disable the capacity for extension in conformity with his original idea.

I have in mind an electric power and lighting station, built a few years ago, which to the observer shows a faulty plan of construction. It is situated on a corner of two streets, with a railroad track forming the third boundary. The engine and dynamo-room is placed on the corner, and the boilers are backed up to the end wall, thus shutting off the natural avenue for extension of the engine and dynamo-room. There is just about room enough between the railroad track and the dynamo-room for the boilers, and, thus built, the plant is capable of extension only by increasing the length of the dynamo-room, as the land is available only in that direction.

A splendid electric railway and power station not yet completed is being constructed for a capacity of 5,000 h. p. and is built near the wharf, with coal bunkers to facilitate the handling of coal, and no expense is being spared to make the plant first class. This station is placed with the end to the street. The engine and generator-room is at the front, with the boilers at the rear, and precluding any extension in that direction. The engine and generator-room will contain ten 500 h. p. tandem compound engines, placed crosswise of the building, and each will be belted directly to a generator. This arrangement, while blocking the natural way of extension, is also faulty as it necessitates very long steam pipes. By placing the boilers at the side of the engine-room, the plant can be enlarged at any time, and it permits the use of comparatively short steam pipes from the boilers to the high pressure cylinders of the several engines.

A careful study of the requirements of a plant before the buildings are begun, will in every case result in benefit to the interests involved.

FIGURES OF STREET CAR TRAVEL IN PHILADELPHIA.

At the annual meeting of the Second and Third Streets Passenger Railway Company president Horace T. Potts submitted a report showing that the road and its branches, exclusive of transfers, carried during the past year 11,944,743 passengers, an increase of 512,111 over 1891. The stockholders present at the meeting were almost unanimous in their expressions favoring the trolley system, and it is understood that at the meeting of the new Board of Directors steps will be taken toward adopting the system on all their lines, including the Frankford branch.

President Jeremiah J. Sullivan, of the Frankford and Southwark Passenger Railroad, and also of the Tenth and Eleventh

Street road, showed to his stockholders that those roads had carried during the past year 22,477,539 passengers, as against 16,267,610 in 1891. There was a very general expression of opinion among the stockholders in favor of adopting the trolley system, and it is thought that at the next meeting of the Board of Directors the matter will be taken up and acted on.

THE RAPID TRANSIT SITUATION.

THE RAPID TRANSIT COMMISSIONERS are still of the opinion that the tunnel plan, suggested by them is the only suitable and effective system for the city, notwithstanding the fact that no responsible bid was made for the franchise when the latter was recently offered for sale, and will, therefore, again offer it at public auction at any time upon information that a proposed purchaser is ready to make a sufficient deposit to justify confidence in his sincerity.

Meantime the Commissioners resolved to ask the Manhattan Elevated Railway to submit plans for proposed extensions of their system to relieve the pressure of urban travel, and the company has responded by suggesting a sufficient number of routes to virtually "double-deck" the city.

The proposed extensions are as follows: From the present Battery Place Station up West street to West Eleventh street, through the latter to Greenwich avenue, thence up Seventh avenue to Forty-fourth street, up Broadway to Fifty-ninth street, up the Boulevard to its intersection with Eleventh avenue at One Hundred and Eighth street, and up Eleventh avenue, through the Washington Heights district to Fort George. A connection of this line with the Sixth avenue line is proposed from the Eighth street station through Greenwich avenue. There would be another connection at Fifty-third street, and it is proposed to extend the Fifty-third street connection west to Tenth avenue and carry a new line up that avenue to the Boulevard line at the intersection at Seventy-first street, which would afford the means of running trains from the Sixth avenue road to that on the Boulevard. The privilege is also asked for a cross-town connection from West street through Watts and Canal to Centre street and down to the bridge, a branch from Sixth avenue at Forty-second street to Fourth avenue and the Grand Central Station, and another from Eighth avenue at One Hundred and Forty-ninth street east to Lenox avenue, down that avenue to One Hundred and Twenty-eighth street, and across to Third avenue. Another extension is desired up Third avenue above the Harlem River to Fordham. In addition to this it is proposed to put a third track on the Second, Third and Ninth avenue lines, with a fourth track through the Bowery.

Mr. Austin Corbin has sent to the Commissioners requesting a conference between the engineers of the Board and those of his proposed tunnels under the East and North Rivers, with a view to a modification of underground plans enabling the two systems to co-operate readily in the transfer of passengers.

DESTRUCTION OF THE PEORIA, ILL., RAILWAY POWER HOUSE.

THE Power House of the Central Railroad Co., of Peoria, Ill., was burned to the ground last week. The engines and dynamos were not running. The engineer and three others were in the building when it caught fire. The fire started in the machine shop and soon spread to the car and power house. The engines and dynamos are total wrecks. There were ten cars in the car house, all of which were burned. The cause of the fire is a mystery, as when it was first discovered the machine shop was all afire; those near tried to put it out with hose belonging to the building but could not, and they were glad to get out alive.

The building was a two-story brick one, only two years old. The loss is estimated as follows:

Power house building	$20,000.00
Engines and Boilers	12,500.00
Machinery	6,500.00
Dynamos and electrical machinery	35,000.00
Cars	30,000.00
Total	$104,000.00

with an insurance of $90,000.00. The company, who operate 20 miles of track, expect to have the Adams street line running this week. They will set up generators at either one of the idle distilleries, or else in the straw board mill, both of which have large engines. The remaining lines will be operated by horse power until current and motor cars can be got.

THE TROLLEY CAR MAIL SERVICE IN ST. LOUIS.

IN THE ELECTRICAL ENGINEER recently appeared an illustrated article on the trolley car mail service in St. Louis. A dispatch from Washington of Jan. 18, now furnishes the following additional information: The report of Postmaster Harlow of St. Louis, made after a two weeks' trial of his street railway postal car service, has been received at the Post Office Department. The St. Louis and Suburban Railway, over which the postal car runs, is a post route eighteen miles long, passes the shipping doors of the Post Office, and has public stations situated directly upon it, one full station three blocks away, and a number of Post Offices upon the road beyond the city limits. Postmaster Harlow says that he has in view a plan by which eight electric cars could wisely be put to this service, by which stations and sub-stations would offer additional facilities for the public and serve as rallying points for carriers, and that the time of twenty or more carriers would thus be saved, and the same men could be put to better use. During the two weeks covered by the report the number of pieces of local mail received and delivered, at a saving of from four to five hours each, has been from three to five hundred daily. Postmaster Harlow regards the trial as eminently successful in every particular.

SAN FRANCISCO STREET RAILWAY EXTENSIONS.

IT is stated that the extensions of the various street railways in San Francisco during the year of '93 will amount to about 85 miles and cost over $3,000,000. The company is devoting much time to the study of electric traction and many of the lines now using horses will adopt the trolley or storage battery. The Kentucky street line is to be extended to Market street and electricity substituted. On Mission street 50,000 yards of grading is to be done, after which the road will be entirely rebuilt, extended to the county line and operated by electricity. It is expected to complete this work in six months. Branches from this and other lines are to be built and will connect with existing and projected cable roads throughout the city. The company say that the trolley will be used for the present, but that they are prepared to adopt any other electric system the promoters of which may prove its practicability.

THE CHICAGO & ST. LOUIS ELECTRIC ROAD.

WE have received the following from the Chicago & St. Louis Electric Railroad Co.:

> "The daily papers have been teeming with stuff in regard to the fight in Congress between the Chicago & St. Louis Electric Road and the General Electric Co., the substance of which is this: The Chicago & St. Louis Electric Road, through Dr. Wellington Adams, and Representative Seth Cobb, of St. Louis, have asked for the right to import certain raw materials for the construction of their generating machinery, and the General Electric Co., through its attorney, E. H. Lewis, is fighting against the granting of this permission
>
> "The stand taken by the Electric Road is this. A multiphase current is to be used, and there are grave doubts as to the ability of the General Electric Co. to produce satisfactory machinery for generating a multiphase current. It has been successfully accomplished on the other side, and for this reason the Electric Road wants to import some of the necessary apparatus; and it surely shows a thoroughness in wanting to get what is no longer an experiment.
>
> "Of course, the General Electric Co. have an axe to grind, and will fight the case to the end. The Chicago & St. Louis Electric Road is in course of construction and will be running on time just the same."

Our own report of the proceedings in Committee, was published last week. The contention that the multiphase apparatus cannot be produced in this country is absurd, even while it may be true that the General Electric Co. has not the specific patent rights.

MISCELLANEOUS.

THE TELEGRAPH AMONG THE MICHIGAN FARMERS.

MR. GEORGE S. TIFFANY, of Tecumseh, Mich., in the January *Engineering Magazine*, says:—

> There is a line in the northern part of Senawee county which was commenced by connecting two farm-houses and has been extended from house to house and village to village until it is now over a hundred miles in length, and connects newspaper offices, doctors' offices, and stores in Adrian, Tecumseh, Clinton, Franklin, Mason, Ridgeway, and Raisin. The farmer keeps up the line across his farm and owns the instrument. One cannot enumerate the benefits it confers, but one which the manager, Mr. Raymond Bowen, of Tecumseh, mentioned to me to-day, it is worthy of special mention. The election returns came in very early from towns on the line and were given to the agent of the Associated Press *in exchange for their despatches*, which were immediately sent over the wire to each farm-house. In receiving news the farmer of Senawee county had an advantage over the business man of New York and Chicago.
>
> "I could not sleep last night," said Mr. Bowen, "for I *lay in bed* listening to the instrument ticking off the election news."
>
> What do you think of that? The Company is named the Commercial Telegraph Co.; but it is a misnomer; it should be named the Farmers' Telegraph Co, for it is such. The system should be extended until every farm-house is bound to every other with cords of steel.

SMASHING LAMP GLOBES AT FAR ROCKAWAY.

THE Far Rockaway, L. I., Electric Light Company is in arms against the wreckers of its lamp globes. The globes afford, after dark, a shining mark for those juvenile marksmen who have no sympathy for corporations and who possess Flobert rifles and bean shooters. The company declares that the expense it is put to for new globes obliterates its profits, and makes some steps to punish the mysterious marksmen imperative. The constabulary has been asked to aid in the matter.

EXPERIMENTS WITH HIGH FREQUENCY ELECTRIC DISCHARGES.

BY

A. A. C. Swinton

THE author has succeeded in passing through his body from hand to hand sufficient electricity to bring the filament of an ordinary 5 c. p. 100 volt incandescent lamp very nearly to full incandescence, or to bring the filament of a 32 c. p. 100 volt lamp to full redness. Practically no sensation was experienced.

The apparatus employed consisted of a large "Apps" induction coil capable of giving 10″ sparks, supplied with current through the ordinary vibrating contact breaker and a resistance consisting of eight 50 c. p. lamps in parallel, from a 105 volt continuous current supply. To the positive and negative terminals of the secondary of the induction coil were connected respectively the inside and outside coatings of three half-gallon Leyden jars, connected in parallel. The disruptive discharge of these jars across an air gap of about a quarter of an inch excited the primary of a simple form of high frequency coil similar to those employed by Mr. Tesla and Prof. Elihu Thomson. The secondary of this coil consisted of 500 turns of No. 26 S. W. G. cotton covered wire wound on a paper tube. Outside this paper tube was a glass tube, upon which the primary, consisting of 10 turns of three No. 16 gutta percha covered wires, in parallel, were wound. The whole coil was immersed in resin oil contained in a wooden trough. The ends of the secondary were connected through small glass tubes, also filled with oil, to brass balls.

On approaching the hand to one of the balls forming the terminals of the oil coil, sparks shoot out from the brush discharge which surrounds it. If the spark is taken on the skin a sharp prick is felt, but on approaching the terminal or touching it with a piece of metal grasped in the hand, or after grasping the terminal itself, practically no appreciable sensation is felt. If the terminal is grasped in this manner with the right hand, sparks will shoot out from the left hand or indeed from any portion of the body, if brought into proximity with another person, a piece of metal, the gas or water pipes or any conducting body. In the experiment referred to, the incandescent lamp was hung by one terminal on a wire connected to earth and connection was made between the other lamp terminal and the coil through the two arms and body by the right hand being brought into contact with one terminal of the oil coil, and a piece of metal grasped in the left hand being approached to the free terminal of the lamp. At the first approach the bulb of the lamp became filled with phosphorescent light, but on reducing the distance between the metal in the left hand and the free lamp terminal, sparks shot out between them and the filament at once became incandescent, the incandescence increasing very nearly to the full normal amount when the piece of metal and the lamp terminal were finally brought into contact.

To produce a similar incandescence of the filament with continuous or alternating currents of ordinary frequency would require about one-fifth of an ampere, and at first sight it would seem that this quantity of current might pass through the arms and body of the operator.

It has been generally assumed that with high frequency currents the current is rendered harmless by reason of the high frequency, in fact, that high frequency renders harmless to the human body currents of a strength that would be dangerous and painful, if not fatal, were the frequency lower. The author is inclined to think that another explanation is possible and that the true fact is, not that high frequency renders harmless a given strength of current that with ordinary frequency would be harmful, but that with high frequency it is possible to obtain effects with exceedingly small currents, that with continuous and ordinary alternating currents can only be obtained by the use of much larger currents.

This hypothesis is probably applicable to many other high frequency effects, but as applied to the above mentioned experiment it is simply this. The lamp filament having a certain definite resistance, with continuous or ordinary alternating currents which pass uniformly or nearly so through the section of the filament, a certain amperage of current is necessary to produce the number of watts required to raise the filament to incandescence. With the high frequency currents on the other hand, as is well understood, the current travels chiefly on the outer surface of the filament, little or none passing through the central portion. The current is in fact merely skin deep. The virtual resistance is therefore very high, as only an extremely small portion of the sectional area of the filament acts as a conductor. There is an ample sufficiency of volts, and though the current is very minute there is a sufficient expenditure of watts to raise the filament to incandescence. The lamp, in fact, ceases to be a 100-volt lamp and becomes, it may well be, a 100,000-volt lamp. As confirming this hypothesis it should be mentioned that while the filament was incandescent, sparks passed between the lamp terminals which were at some distance apart, this being evidence that there was a difference of potential amounting at least to thousands of volts between the two ends of the filament.

Returning to the experiments, several other curious results were obtained. If instead of connecting the lamp to the coil through the human frame a wire was used, the filament became much brighter than in the previous experiment. In fact, it gave considerably above its normal candle power. From this it was evident that the human body offered considerable opposition of some description to the passage of the electricity. In order to form some idea of the amount of this opposition the body was again inserted in the circuit between the coil and the lamp as previously, and the thumbs of the two hands brought near together. Sparks about one-quarter of an inch in length were found to pass between them, evidencing that the two hands of the operator had a difference of potential between them apparently equal to some thousands of volts. When the sparks passed between the hands, or when the wrists were brought into contact so, as it were, to short circuit to some extent the resistance of the arms and body, the filament became very appreciably brighter. It should be mentioned that when the sparks were allowed to pass between the hands very perceptible shocks were felt in the wrists.

Another experiment was to connect one lamp terminal by a wire to the coil, connect the other lamp terminal to earth, and short circuit the lamp through the body by grasping the coil terminal with one hand and a piece of metal connected to earth with the other. The effect of so doing was to reduce the incandescence of the filament to rather less than one-half its normal amount, half of the available current going apparently through the lamp, the other half through the body.

With the lamp terminal connected to the coil, it was found unnecessary to connect the other lamp terminal to earth to produce incandescence, all that was necessary being to touch this lamp terminal with a piece of metal held in the hand. That the incandescence of the filament produced under these conditions was due to the electrostatic capacity of the operator and not to his forming a connection to earth, was evidenced by the fact that it made no perceptible difference whether he stood on the floor or on an insulated stool.

In all the above experiments the second terminal of the oil coil was free and not connected to anything. It was however found that the effect of a second operator touching this terminal, or of connecting it by wire to earth, was to diminish the incandescence of the lamp filament. It was also found that the filament incandesced to a greater degree of brightness when connected as above between one terminal of the coil and earth, than when it was directly connected between the two terminals of the coil. This seems to show that capacity has much to do with the results obtained.

It should also be mentioned that in some of the experiments there was a decided tendency for the filament to vibrate in unison with the contact breaker of the induction coil. In fact in some cases the amplitude of vibration was sufficient to cause the end of the filament to beat against the glass of the lamp bulb.

ALTERNATE CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY.—III.

(Concluded.)

BY NIKOLA TESLA.

One of the most interesting results arrived at in pursuing these experiments, is the demonstration of the fact that a gaseous medium, upon which vibration is impressed by rapid changes of electrostatic potential, is rigid. In illustration of this result an experiment may be cited: A glass tube about 1 inch in diameter and 3 feet long, with outside condenser coatings on the ends, was exhausted to a certain point, when, the tube being suspended freely from a wire connecting the upper coating to one of the terminals of the coil, the discharge appeared in the form of a luminous thread, passing through the axis of the tube. Usually the thread was sharply defined in the upper part of the tube and lost itself in the lower part. When a magnet or the finger was quickly passed near the upper part of the luminous thread, it was brought out of position by magnetic or electrostatic influence, and a transversal vibration like that of a suspended cord, with one or more distinct nodes, was set up, which lasted for a few minutes and gradually died out. By suspending to the lower condenser coating metal plates of different sizes, the speed of the vibration was varied. This vibration would seem to show beyond doubt that the thread possessed rigidity, at least to transversal displacements.

Many experiments were tried to demonstrate this property in air at ordinary pressure. Though no positive evidence has been obtained, it is thought nevertheless, that a high frequency brush or streamer, if the frequency could be pushed far enough, would be decidedly rigid. A small sphere might then be moved within it quite freely, but if thrown against it the sphere would rebound. An ordinary flame cannot possess rigidity to a marked degree because the vibration is directionless; but an electric arc, it is believed, must possess that property more or less. A luminous band excited in a bulb by repeated discharges of a Leyden jar must also possess rigidity, and if deformed and suddenly released should vibrate.

From like considerations other conclusions of interest may be made. The most probable medium filling the space is one consisting of independent carriers immersed in an insulating fluid. If through this medium enormous electrostatic stresses are assumed to act, which vary rapidly in intensity, it would allow the motion of a body through it, yet it would be rigid and elastic, although the fluid itself might be devoid of these properties. Furthermore, on the assumption that the independent carriers are of any configuration such that the fluid resistance to motion in one direction is greater than in another, a stress of that nature would cause the carriers to arrange themselves in groups, since they would turn to each other their sides of the greatest electric density, in which position the fluid resistance to approach would be smaller than to receding. If in a medium of the above characteristics a brush would be formed by a steady potential, an exchange of the carriers would go on continually, and there would be less carriers per unit of volume in the brush than in the space at some distance from the electrode, this corresponding to rarefaction. If the potential were rapidly changing, the result would be very different; the higher the frequency of the pulses, the slower would be the exchange of the carriers; finally, the motion of translation through measurable space would cease, and, with a sufficiently high frequency and intensity of the stress, the carriers would be drawn towards the electrode, and compression would result.

An interesting feature of these high frequency currents is that they allow to operate all kinds of devices by connecting the device with only one leading wire to the source. In fact, under certain conditions it may be more economical to supply the electrical energy with one lead than with two.

An experiment of special interest is the running, by the use of only one insulated line, of a motor operating on the principle of the rotating magnetic field enunciated by the author a few years ago. A simple form of such a motor is obtained by winding upon a laminated iron core a primary and close to it a secondary coil, closing the ends of the latter and placing a freely movable metal disc within the influence of the moving field. The secondary coil may, however, be omitted. When one of the ends of the primary coil of the motor is connected to one of the terminals of the high-frequency coil and the other end to an insulated metal plate, which, it should be stated, is not absolutely necessary for the success of the experiment, the disc is set in rotation.

Experiments of this kind seem to bring it within the reach of possibility to operate a motor at any point of the earth's surface from a central source, without any connection to the same except through the earth. If, by means of powerful machinery, rapid variations of the earth's potential were produced, a grounded wire reaching up to some height would be traversed by a current which could be increased by connecting the free end of the wire to a body of some size. The current might be converted to low tension and used to operate a motor or other device. The experiment, which would be one of great scientific interest, would probably best succeed on a ship at sea. In this manner, even if it were not possible to operate machinery, intelligence might be transmitted quite certainly.

In the course of this experimental study special attention was devoted to the heating effects produced by these currents, which are not only striking, but open up the possibility of producing a more efficient illuminant. It it sufficient to attach to the coil terminal a thin wire or filament, to have the temperature of the latter perceptibly raised. If the wire or filament be inclosed in a bulb, the heating effect is increased by preventing the circulation of the air. If the air in the bulb be strongly compressed, the displacements are smaller, the impacts less violent, and the heating effect is diminished. On the contrary, if the air in the bulb be exhausted, an inclosed lamp filament is brought to incandescence, and any amount of light may thus be produced.

The heating of the inclosed lamp filament depends on so many things of a different nature, that it is difficult to give a generally applicable rule under which the maximum heating occurs. As regards the size of the bulb, it is ascertained that at ordinary or only slightly differing atmospheric pressures, when air is a good insulator, the filament is heated more in a small bulb, because of the better confinement of heat in this case. At lower pressures, when air becomes conducting, the heating effect is greater in a large bulb, but at excessively high degrees of exhaustion there seems to be, beyond a certain and rather small size of the vessel, no perceptible difference in the heating.

The shape of the vessel is also of some importance, and it has been found of advantage for reasons of economy to employ a spherical bulb with the electrode mounted in its centre, where the rebounding molecules collide. It is desirable on account of economy that all the energy supplied to the bulb from the source should reach without loss the body to be heated. The loss in conveying the energy from the source to the body may be reduced by employing thin wires heavily coated with insulation, and by the use of electrostatic screens. It is to be remarked, that the screen cannot be connected to the ground as under ordinary conditions.

In the bulb itself a large portion of the energy supplied may be lost by molecular bombardment against the wire connecting the body to be heated with the source. Considerable improvement was effected by covering the glass stem containing the wire with a closely fitting conducting tube. This tube is made to project a little above the glass, and prevents the cracking of the latter near the heated body. The effectiveness of the conducting tube is limited to very high degrees of exhaustion. It diminishes the energy lost in bombardment for two reasons: First, the charge given up by the atoms spreads over a greater area, and hence the electric density at any point is small, and the atoms are repelled with less energy than if they would strike against a good insulator; secondly, as the tube is electrified by the atoms which first come in contact with it, the progress of the following atoms against the tube is more or less checked by the repulsion which the electrified tube must exert upon the similarly electrified atoms. This, it is thought, explains why the discharge through a bulb is established with much greater facility when an insulator than when a conductor is present.

During the investigations great many bulbs of different construction, with the electrodes of different material, were experimented upon, and a number of observations of interest were made. It was found that the deterioration of the electrode is the less, the higher the frequency. This was to be expected, as then the heating is effected by many small impacts, instead of by fewer and more violent ones, which quickly shatter the structure. The deterioration is also smaller when the vibration is harmonic. Thus an electrode, maintained at a certain degree of heat, lasts much longer with currents obtained from an alternator, than with those obtained by means of a disruptive discharge. One of the most durable electrodes was obtained from strongly compressed carborundum, which is a kind of carbon recently produced by Mr. E. G. Acheson. From experience, it is inferred, that to be most durable, the electrode should be in the form of a sphere with a highly polished surface.

In some bulbs refractory bodies were mounted in a carbon cup and pushed under the molecular impact. It was observed in such experiments that the carbon cup was heated at first, until a higher temperature was reached; then most of the bombardment was directed against the refractory body, and the carbon was relieved. In general, when different bodies were mounted in the bulb, the hardest fusible would be relieved, and would remain at a considerably lower temperature. This was necessitated by the fact that most of the energy supplied would find its way through the body which was easier fused or "evaporated." Curiously enough it appeared in some of the experiments made, that a body was fused in a bulb under the molecular impact by evolution of less light than when fused by the application of heat in ordinary ways. This may be ascribed to a loosening of the structure of the body under the violent impacts and changing stresses.

Some experiments seem to indicate that under certain conditions a body, conducting, or non-conducting, may, when bombarded, emit light, which to all appearance is due to phosphorescence, but may in reality be caused by the incandescence of an infinitesimal layer, the mean temperature of the body being comparatively small. Such might be the case if each single rythmical impact were capable of instantaneously exciting the retina, and the rythm just high enough to cause a continuous impression in the eye. According to this view, a coil operated by disruptive discharge would be eminently adapted to produce such a result, and it is found by experiment that its power of exciting phosphorescence is extraordinarily great. It is capable of exciting phosphorescence at comparatively low degrees of exhaustion, and also projects shadows at pressures far greater than those at which the mean free path is comparable to the dimensions of the vessel. The latter observation is of some importance, inasmuch as it may modify the generally accepted views in regard to the "radiant state" phenomena.

A thought, which early and naturally suggested itself, was to utilize the great inductive effects of high frequency currents to produce light in a sealed glass vessel without the use of leading-in wires. Accordingly, many bulbs were constructed in which the energy necessary to maintain a button or filament at high incandescence, was supplied through the glass either by electrostatic or electrodynamic induction. It was likewise easy to regulate the intensity of the light emitted by means of an externally applied condenser coating connected to an insulated plate, or simply by means of a plate attached to the bulb which at the same time performed the function of a shade.

A subject of experiment, which has been exhaustively treated by Prof. J. J. Thomson, has been followed up independently by the author from the beginning of this study, namely, to excite by electrodynamic induction a luminous band in a closed tube or bulb, In observing the behavior of gases, and the luminous phenomena obtained, the importance of the electrostatic effects was noted and it appeared desirable to produce enormous potential differences, alternating with extreme rapidity. Experiments in this direction led to some of the most interesting results arrived at in the course of these investigations. It was found that by rapid alternations of a high electrostatic potential, exhausted tubes could be lighted at considerable distance from a conductor connected to a properly constructed coil, and that it was practicable to establish with the coil an alternating electrostatic field, acting through the whole extent of a room and lighting a tube, wherever it was placed in the same. Phosphorescent bulbs may be excited in such a field, and it is easy to regulate the effect by connecting to the bulb a small insulated metal plate. It was likewise possible to maintain a filament or button mounted in a tube at bright incandescence, and in one experiment, a mica vane was spun by the incandescence of a platinum wire.

It is hoped that the study of these phenomena, and the perfection of the means for obtaining rapidly alternating high potentials, will lead to the production of an efficient illuminant.

THE UTILIZATION OF NIAGARA.—II.

(*Concluded.*)

BY PROF. GEORGE FORBES, F.R.S.

Having now given some account of the hydraulic part of the work, and of the engineering construction, it will be well to say something about the manner in which this power is to be distributed and utilized. The directors of the company were very anxious that the best advice possible should be obtained on this point, and, in 1890, they appointed a Commission, which sat in London, under the presidency of Lord Kelvin, assisted by Professor Mascart, of Paris, Colonel Turrettini, of Geneva, and Professor Coleman Sellers, of Philadelphia, to consider the various proposals which had been made by several engineers and manufacturing firms who had been specially invited to submit projects for the utilization and distribution of the power developed at Niagara Falls. Professor Unwin, who is now considering the problem of dealing with the hydraulic engineering for utilizing the Horseshoe Fall, on the Canadian side, was the secretary. Among the projects submitted, the two most promising means of distribution were compressed air and electricity, but the further inquiries which have proceeded since the Commission was closed have resulted in the decision to adopt electricity. At one time it was thought that a large number of mills would be worked on the same plan as the paper company spoken of above—that is to say, by driving the mills directly by turbines in separate wheel pits having access to the great tunnel—but the expense of digging separate wheel pits for every mill is serious, besides that, this plan would involve a considerable extension of the tunnel; and it has been considered best, not only for transmission to a distance, but also for most of the local distribution, to employ electricity for supplying the power to the different mills and workshops. The question of using compressed air was seriously considered, but it also gave way in convenience and economy to electricity.

Now, when I come to speak of the electrical part of the scheme I feel some diffidence, because we are at the present moment on the eve of settling the type of machinery to be used. I have before me for consideration more than 20 distinct plans of the 5,000 h. p. generators which may be used. Some of these are for continuous currents, others for alternating currents, and while I naturally have definite views as to which of the plans proposed is the most practical, I confess that, even at this time, I have an open mind which would be free to accept anything which seems more valuable than the best design we have received as yet. Of one point I may assure you most definitely, and that is, that there is not the slightest difficulty in making this work successful from an engineering as well as from a commercial point of view. My difficulties have consisted chiefly in the number of different ways by means of which it was possible to attain the results required. The types of machine which have been proposed vary in many essential features, and in none more than in the important item of the weight of the revolving part, which varies in these designs from 7 or 8 tons up to 60 tons; but it is quite remarkable that in a science of comparatively recent growth, as in the distribution of power electrically, there should be so few differences of opinion as to the means to be adopted, and the character of the machinery to be used. This is the more remarkable when I contrast it with any ordinary engineering machinery which is the growth of a hundred years or more. Even in the matter of such a common-place article as a steam boiler, the differences of view which exist among mechanical engineers are quite surprising, for it would have been supposed that, after so long a period of practical experience, the views of all engineers would have been brought into harmony by this time. The question of broad and narrow gauge has equally disturbed the equanimity of engineers, and in every department of steam engineering we find the widest differences of views existing among engineers. It is consequently a little surprising that electricians are so nearly agreed as to the methods and machinery to be used.

There are two great classes into which this problem may be divided, depending upon the use either of continuous or alternating currents. Both of these are thoroughly available for the purposes under consideration, and each has some special advantages. A few years ago there was a certain dread of the use of alternating currents among a certain class, but this has gradually disappeared. Heated arguments were formerly used on both sides, but at the present day it is possible for all independent engineers to discuss these matters on a basis of pure reason, and no serious differences arise when the relative advantages of the two kinds of current are discussed among capable engineers. The continuous current has the advantage that the dynamos of this kind have been made in larger quantities, and that we can at a moment's notice procure on the market a motor of any moderate size. They can also be coupled in series or in parallel with the utmost facility. The alternating current dynamo has the advantages that it employs no commutator—a source both of expense and of risk in a continuous current machine, and also that the alternating current can be transformed up to a higher, or down to a lower pressure. A low pressure dynamo is a machine of more solid construction than a high pressure one. When the current has been created at low pressure, it can be converted by a transformer into high pressure, and so carried economically along fine wires to a distance where it can be reduced in pressure by a second transformer, and supplied to motors in a perfectly safe condition. With the continuous current, on the other hand, the motors must be of the same high pressure as that which is used upon the line, even if we adopt the combination of a motor and dynamo as a transformer for supplying low pressure current to workshops. Such an apparatus is far more objectionable than the alternating current transformer, which is at rest during the whole time of its action. It is also more expensive than the latter. When the distance to which the power has to be transmitted is short, it may become more economical to use low pressure and thick conductors instead of high pressure with transformers and thin conductors, but the distance to which this advantage extends is very short. The experiments which were made last year between Lauffen and Frankfort, show that we need not have the slightest fear about using so much as 20,000 volts in the transmission between Niagara and Buffalo, and if a subway be constructed over this distance in which to carry the conductors, we need not fear any climatic troubles, and inspection will be so easy that the conductors will always be in good order.

In 1890 I laid before the Commission my views as to the manner in which the desired results might best be obtained, and expressed myself at that time in favor of the use of alternating currents, most specially for the transmission to Buffalo, and I think that on this point there are no two opinions at the present time, although considerable opposition to this view was shown at the earlier date.

Alternating current motors may be divided into two classes, synchronizing and non-synchronizing motors. The former are mechanically identical with the alternating current generator, and revolve at constant speed governed by the speed of the generating machine. Of the latter class those best known are those depending for their action on principles discovered independently by Tesla and Ferraris. The former class have been in considerable use both in Europe and in America on what may be spoken of as a large scale, and they are found to equal continuous current motors in efficiency. The latter class, especially those which are described as rotary phase motors, have been gradually developed since I related my experience with them to the Commission two years ago, and their efficiency, as guaranteed by the makers, now amounts to 90 or 92 per cent. Continuous current motors have been used to so great an extent, and more especially in electrical tramways, that it is unnecessary to enlarge upon their capabilities. There are many other kinds of motors which are available, but it would be tedious if I were to describe to you the action of all these different varieties. I will only mention one more system, which may be described as a combination of alternating and continuous currents, and which promises to do important work in the future. In the ordinary usage of a continuous current, the dynamo originally generates an alternating current, and the commutator is applied to the dynamo to convert it into a continuous current, and this procedure prevents us from taking advantage of that valuable adjunct, the transformer. Many engineers are now working at a plan whereby the commutator, instead of being put upon the dynamo, is put at the other end of the line after the high pressure alternating current has been reduced in pressure, and we are thus able to distribute a low pressure continuous current to the motors at the distant station, while we have been using a high pressure alternating current over the line. I will not say at present which of the numerous methods which are available to us are most likely to be adopted. I have said enough to show you that we have ample means at our disposal to establish a thoroughly successful plant from an engineering point of view. As to the commercial side of the question I must satisfy myself with stating to you in general terms that after having worked out the cost in every one of the different methods which have been proposed, I have no hesitation is assuring you that the cost at which a horse-power per annum can be sold, either in the neighborhood of Niagara Falls or at Buffalo, is such as to make the enterprise certain of success from a commercial point of view.

Hitherto I have sketched out the general engineering questions which have arisen, but beyond that there is a great deal as to the policy which has been adopted by the directors of this company. Those who have taken the most active part in its development are Mr. E. D. Adams, the president, Mr. L. Stetson and Mr. E. A. Wickes, vice-presidents, and Mr. W. B. Rankine, secretary and treasurer. The consulting engineers include Professor Coleman Sellers, whose knowledge and experience of all classes of machinery is so well known; Mr. Bogart, who has had the construction of large engineering works under his charge; and Mr. Clemens Herschel, who has devoted his life to the development of hydraulic enterprises; while Col. Turrettini acts as foreign consulting engineer, my own position being that of electrical consulting engineer. Mr. Burbank is the resident consulting engineer, and Mr. Albert Porter the resident engineer.

The directors of the company have shown great foresight in a great deal of their work. The capacity of the present tunnel is sufficient to provide 100,000 h. p. applied to the turbines. Rights of way have been obtained for another tunnel of the same capacity on the American side. On the Canadian side a concession has been granted for utilizing the Horseshoe Falls, and the extent to which these will be used may probably reach 250,000 h. p. Thus we have in all 450,000 h. p. available.

Early in the history of this concern, before it had reached anything like a practical stage, about 1,500 acres of land had been bought up in the neigborhood of Niagara Falls, and it is intended to develop this land as much as possible so as to make a great manufacturing centre. A great number of applications for power have already been received, and it becomes perfectly evident that the establishment of each separate industry will bring to the neighborhood a large number of new industries. Thus we expect very shortly to have a copper refinery for electrolytic processes. This will naturally bring wire manufactories to the spot. Electric cables will also be made there, where the wire can be obtained cheapest. The wants of the company alone are sufficient to require the establishment of an electrical factory, and the facilities for transporting machinery by land or water will be such as to make it an important centre for the manufacture of large electric machinery, either for lighting, for traction, or other purposes. And so it appears likely to proceed, the success of one industry leading to the establishment of another, until the whole land of the company, and much more besides, is used up in the raising of what may eventually become the greatest manufacturing centre of the United States.

In order to give facilities of transport to those who establish themselves here, ample wharfage accommodation will be established, a matter which is comparatively easy, since the company owns several miles of river frontage. With the same object in view a terminal railway has been built, and is now at work, connecting the principal streets belonging to the company with the three great lines of railroad which pass beside it. Contracts have already been given out for the construction of laborers' houses, and before long this part of the new city will have made sensible progress.

The company has also undertaken the water supply of the city, including the old part, which was insufficiently supplied, and they are also dealing with the matter of sewage.

Altogether, I may briefly state the impression which has been thrust upon me by an examination of the plans and works of the company, in saying that they have taken a most comprehensive view of the situation, and have proceeded up to the present with an amount of caution and foresight that cannot but augur well for the future of the enterprise.

I have often been asked whether the diversion of the waters of the Niagara River will affect the picturesque character of the Falls. I do not think it will. The present tunnel will divert 100,000 h. p. The company has rights for constructing a parallel tunnel of like capacity. The Canadian concession will allow of 250,000 h. p. being utilized. Thus we have a total of 450,000 h. p. which may be used, being about 12 per cent. of the total water. These are the utmost limits to which the company can divert the river, and in their American charters they have, unsolicited, limited their demands to 200,000 h. p. on that side of the river. I do not think that a difference of 12 per cent. in the flow of the water would be noticeable to the tourists who come to see the Falls. But I think it improbable that all this power will be utilized for a long time to come. If we put the value of a horse-power day and night at only £5 per annum, the above output represents an income of £2,450,000 per annum.

With regard to ruining the amenities of the place, we need not fear anything from the action of the company, but this has already been largely done by the Government of Ontario, to its lasting disgrace, for the sake of a paltry addition to their revenue. By the energy of Lord Dufferin, the Canadian banks of the river near the Falls were lately reserved for the people as a park, called Victoria park. The Americans at the same time reserved the American shore and Goat Island for the people. Victoria park was one of the loveliest spots on earth, where you could enjoy the scenery in quiet. This is all spoilt now. A concession has been granted for a railway, which has now been built with almost indecent haste. It goes along the edge of the cliff where formerly one could walk in peace and safety. It goes through the lovely Dufferin Islands, where massive iron bridges have been built for a double track of railway, and thus for the sake of a paltry annual income the Government of Ontario has mortgaged the benefits conferred on the world by Lord Dufferin.

In concluding this paper, I must express my admiration for the policy of forethought displayed by the directors of the company that is undertaking the harnessing of Niagara. They traveled all over the world to see what had been done already in transmitting power, and before settling on any plans they spared no expense to get the best advice through the Commission they appointed. The same forethought was shown in securing the rights of way for two tunnels on the American side and getting the control of the Canadian concession; also in buying up the land which is to be the site of the new city. As another example of this spirit, I may say that when I was appointed as their electrical consulting engineer, I was instructed to visit on their behalf and report to them on any works in any part of the world that seemed to me likely to be of use in giving us more information about the distribution of power by electricity. I am sure that you will all agree with me that a work of this magnitude and importance, commenced and carried out with so much practical wisdom deserves to succeed, and I trust that many of you when on your way next year to visit the Chicago Exhibition will be able to stop at Niagara Falls, and see for yourselves the way in which these vast waste forces are being harnessed to the service of man.

ELECTRICAL RECORDING METERS.[1]—I.

BY CARYL D. HASKINS.

A BRIEF history of the evolution of the electric meter would be very appropriate, but repetition is odious, and I beg to refer all who are interested in the early history and genealogy of the meter to that most interesting and complete paper on this subject read before the Institute[2] by Mr. George W. Walker, May, 21, 1891.

The earliest meter patent was granted in 1872 to Mr. S. Gardner, of New York City, and the principle of a magnetic or electro-magnetic release for a simple clock movement, is preserved in two or three so-called time-counters to-day, and is doubtless very useful for many purposes; as for example in the Spaulding clock for registering the hours of use of a motor, or other similar devices for registering the hours of use of arc circuits. These devices I shall neglect; they are not meters within the true sense of the word, and their simplicity is obvious.

Before undertaking any description, a few words may be appropriately devoted to the question of the unit by which it is most desirable to measure electrical power in use.

The ampere has been, perhaps is to-day, the popular unit for the measurement of electricity supplied; yet, on careful consideration, how very meaningless for work of this kind, is the ampere unit. Had we but one standard voltage in use for lighting and for power, and for other purposes, no unit could be better than the ampere-hour for meter measurement; but unfortunately or fortunately, as the case may be, there is scarcely a potential, between 5 and 2,000 volts, which does not more or less imperatively call for measurement by meter to-day, and if the ampere unit is to be retained, then it will become necessary to reconcile ourselves to the use of an endless number of constants, or to a still more endless schedule of ampere-hour rates.

We wish to measure power delivered; in fact we wish to know how much coal a group of lamps is consuming. This points directly to the watt, and I venture to assert that careful consideration will invariably show that the watt is the only true unit for the measurement of electricity by meter. Unless, perchance, we adopt the cubic foot, as has at least one central station in the United States; a very amusing but equally practical demonstration of American ingenuity.

The earliest successful meters if we consider classes rather than individual instruments, were the chemical meters, closely followed by thermo-meters. The chemical meter is obviously capable of giving most accurate results; in fact with proper manipulation, it is very doubtful whether any measuring device, which has up to to-day been designed, could more correctly sum up passing power. It is in the manipulation and care which such meters require, that their fault lies—if fault there be.

It will be useless for me to waste the time and patience of my kind listeners, by describing to them the eminently successful and generally popular Edison chemical meter, and I will not attempt to do so.[3] An electro-plating bath in its meter form as generally used, does not, however, give a dial indication, and the consumers ask for a dial indication almost invariably, unless they have already become thoroughly familiarized with Edison meters as used by many large Edison stations. Many very ingenious and some quite successful attempts have been made to actuate a train of gears by the electro-deposition of an electrolytic bath,[1] such as the Edison "walking-beam" meter. Again we have a modification of the same device in the form of a wheel bearing a number of electrodes, and on the same principle setting up continuous rotation. It should be noted that in this first digression from the chemical meter, we at once meet with the prime factor of difficulty in all motor meter construction—that of friction, which, if uncompensated, must invariably introduce more or less serious error.

---

[1] Abstract of a paper read before the American Institute of Electrical Engineers, Jan. 17, 1893.

[2] *Transactions*, A. I. E. E., vol. viii, p. 351.

[3] See Jenks on the Edison Chemical Meter, *Transactions*, A. I. E. E., vol. vi., p. 26.

Another form of self-registering electrolytic meter has a cathode plate suspended from a spring-balance, an ordinary sensitive spring weighing machine, and the heavier the cathode grows, so much greater is the registration of the spring indicator. This device is perhaps preferable to the reciprocating movement, but is limited in the capacity of the spring, and probably lacks sensitiveness to small amounts, being dependent of course solely upon the nicety of construction in the spring-balance.

Mercury has at times been employed in the construction of electrolytic meters, and with at least moderate success, for with a mercury anode and a cathode of the same or other material, a record easily measured may be obtained, and such a meter may even be made self-registering in a graduated tube or by half a dozen other more or less simple means.

Another form of chemical meter formerly quite popular among inventors, depended for its registration upon the decomposition of water, generally acidulated water, and sometimes upon the decomposition of more volatile substances. This class of meter may very properly be divided under two heads: First, those meters simply dependent upon the measurement of the gas developed by the decomposition of water through any gas registering device. In fact, we may say that such meters are mere decomposing baths connected to a gas meter. There are some devices of merit which may be classed under this head, but the principle is probably not commercial, for we have nothing very successful of this kind in use to-day.

One of the more ingenious meters of this kind provides a diagonally placed rotating wheel with pockets; the decomposition takes place directly under each pocket progressively, and as the air pocket fills with gas, the wheel rotates sufficiently to free this gas at the surface of the fluid, bringing another pocket into place. Others have a rising and falling diaphragm like the popular gas meter, and still others, a delicately poised air fan over a minute aperture. This last device is obviously most inefficient.

The second group of meters under this classification brings us to the thermo-meters; a typical group containing a few meters of more or less pronounced merit.

Those thermo-meters depending upon volatilization of a fluid, generally have two or more sealed bulbs partly filled with some volatile fluid, as, for example, naphtha or ether. When two such bulbs are used, they have generally been mounted on a walking-beam mechanism combined with a pole-changer; each bulb containing some kind of a rheostat or heat developing device dependent for its heat on the current passing through the meter, the two bulbs communicating with one another. To be successful, such a device must be very sensitive, and to be sensitive, the construction must be of a more or less expensive character, and so delicate as to be to a greater or less degree prohibitive. Like the walking-beam meters just described, instruments of this class have been designed with a number of bulbs mounted on a rotating wheel; the same actuating principle holding true for all such devices.

Another ingenious form of thermo-meter, no longer in any sense a chemical meter, is an instrument dependent for its action upon the heat in a confined but circulating atmosphere. Thus a rheostat dependent for its heat upon the amount of current passing, is so arranged as to heat a body of air, which, by the peculiar construction of its receptacle, at once commences to circulate more or less rapidly, dependent upon the heat. It is obvious, that if a delicate air fan, a screw propeller in fact, be suspended over such a circulation of air, its speed would increase with the speed and volume of circulation, and one of the most ingenious and most interesting meters that it has ever been my good fortune to see, is the Forbes meter,[2] constructed on this plan. But here friction is the most serious consideration; the torque obtained in this manner being necessarily small.

While the Forbes meter cannot perhaps be properly considered as a motor meter in the true sense of the word, it still must be classed as such in a certain sense, and I think it may safely be accepted as an axiom, that to be successful in practical operation, a motor meter of any kind must be of high torque, for it is only by the combination of high torque and compensated friction that accurate results can be obtained on light loads. I might say that almost any one can build a meter which will record fairly accurately on heavy loads; the difficulty is to build a sensitive and accurate meter for very light loads down to one lamp.

Another ingenious and quite positive form of heat meter consists of two metallic rods, or in some cases of two bi-metallic rods, somewhat similar to an ordinary thermostat; such meters being in fact a simple application of the thermostat principle to a recording device. Two rods of this kind may be placed vertically, one under each end of a walking-beam mechanism, the familiar pole-changing device being again brought into play to throw the current first through one rod and then through the other. The character of the walking-beam must be such, that only a slight movement is needed to actuate the recording mechanism and also the pole-changer. I think no comments are needed on such a device as this; it probably lacks sensitiveness to a marked degree and it has other objections which are sufficiently apparent.

Probably better than this is the system of bi-metallic rods with one contracting and one expanding side, which bend to right and left, or up and down, with a rapidity dependent upon the strength of the current, a pole-changer of course being used as before. The method of actuating a train of gears by this system is comparatively simple, and not open to as many objections as the device just described,

I have neglected to state heretofore that the bulk of the thermo-meters are actuated on the shunt principle. It is obviously out of the question to operate a pole-changer by means of a meter, which shall cause one to break the full current passing to the lamps. As a rule, a very small portion of the total current is carried through the meter around a positive shunt. Instead of shunting the current, this device has at times been applied to alternating work by the introduction of a kind of transformer, which takes a few turns of wire in series with the lamps and transfers the energy through a secondary to actuate the meter; thus the meter is not on the lamp circuit at all, but on the independent secondary. But this intervention of induction is probably not desirable in cases of this kind.

A patent issued in the year 1889 to a Mr. Dahl, tells us of another quite unique form of thermo-meter, and this is probably the only heat meter actuated by an actual field and armature arrangement. In this instrument, the inventor provides a field of iron excited by a few series turns on the lamp circuit. The strength of the field should therefore bear a more or less definite relation to the amount of current passing through its turns. I will not comment upon how direct this relation would be. It will suffice to say that the introduction of iron in the construction of any meter of this character is probably detrimental to its accuracy to a quite marked degree. On a shaft in the meter which we are describing, is suspended a kind of armature consisting of a flat disc-like ring of iron, supported by a number of spokes and mounted as a wheel; in fact it is mounted on a quite ordinary shaft mechanism suspended in proper bearings. The iron portion of the wheel rotates between the poles of the electro-magnet, or at times permanent magnet, just described. We have, in fact, a disc armature rotating in such a manner as to pass between two poles of a more or less strong field. On the principle of the familiar thermo-magnetic motor, rotation is obtained in this meter by so placing coils of wire or other suitable material under certain portions of the disc and in series with the lamp circuit, that the disc is differentially heated at the proper point; thus, with the peculiar armature construction described, a thermo-magnetic action is set up, somewhat akin probably to the action of the thermo-pile. The portion of the disc heated, is attracted toward the field coils, and thus the disc being progressively heated and cooling rapidly owing to its thinness, continuous rotation is set up.

I might add here, at the risk of digressing from my subject, that there is probably no known indicating device from the Cardew voltmeter to the Sir Wm. Thomson balance which could not be so applied as to make a more or less accurate clock meter.

The last thermo-meter now under consideration is also a thermometer (a commentary perhaps on the English language). An ordinary thermometer of somewhat modified construction, is surrounded at the bulb by a coil of wire in series, or in shunt, with the circuit to be measured. It is apparent that the rise and fall of this thermometer will be *more or less* dependent upon the heat developed by the coil, and the heat again will be more or less dependent upon the current passing, but, of course, the temperature of the surrounding atmosphere must necessarily introduce serious error.

Now, it has been more than once suggested, though never patented, I believe, that a constant ray of light supplied, we will say by an electric lamp burning when the meter is in circuit, if thrown upon this thermometer could be made to photographically mark on rotating sensitized paper, actuated by clockwork at uniform speed, a line, or rather a solid block of light whose lower termination or line of demarkation would represent the height of mercury in the tube. Thus, we have a curve of registration which only needs to be integrated with a planimeter to determine the consumption, always supposing that the indicating device is correct. I have said, "only needs to be integrated." How desirable a meter would be in practical service whose record needs to be integrated, can best be left to the judgment of the station manager and the public.

THE NEW STANLEY TRANSFORMERS.

It is now nearly two years since the announcement was made that the manufacture of transformers had been begun by a company specially devoted to this branch and unconnected with any of the large companies manufacturing the other requisites to an alternating system. The inaugurators of this practice, the Stanley Electric Manufacturing Co., have since then followed consistently the course mapped out by them, devoting their attention almost exclusively to the perfection of the transformer. While their very first products were an advance upon anything that had been produced theretofore, experience has enabled them to still further improve their apparatus not only in the matter of electrical efficiency, but also in regard to its mechanical details.

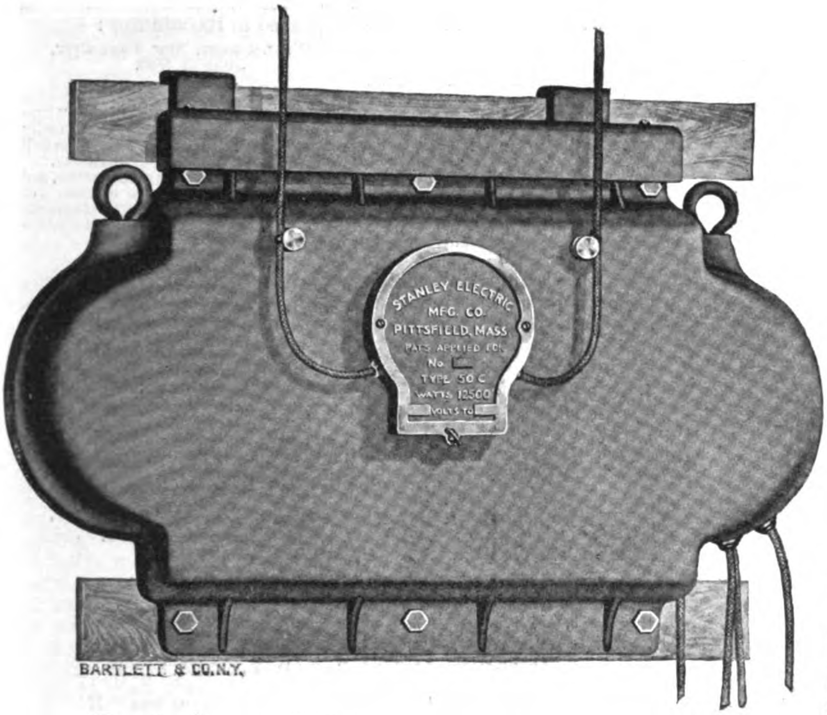

Fig. 1.—Stanley 250-Light Transformer. Out-Door Type.

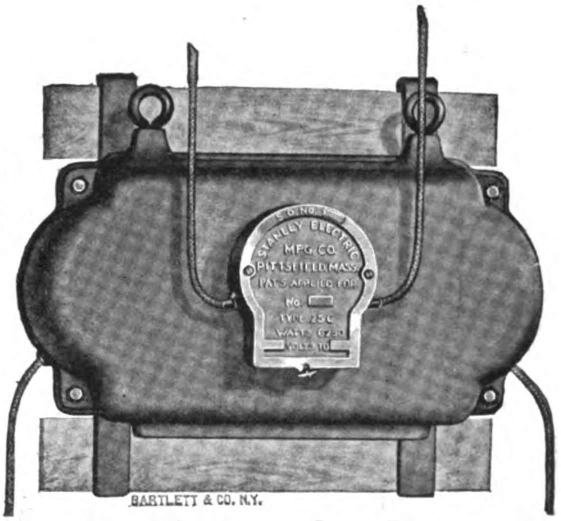

Fig. 2.—Stanley 125-Light Transformer.

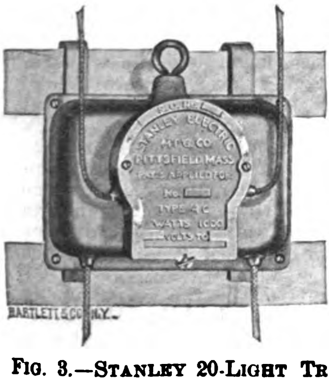

Fig. 3.—Stanley 20-Light Transformer.

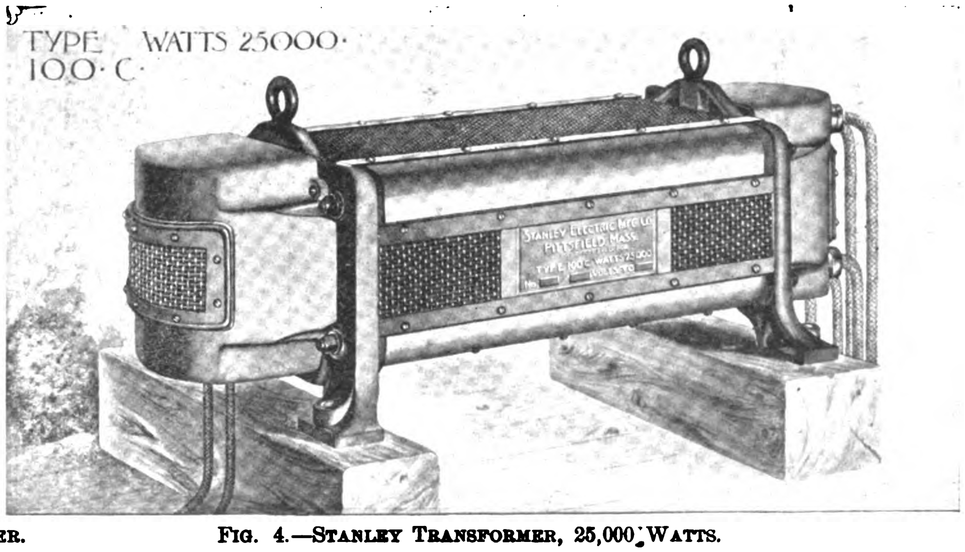

Fig. 4.—Stanley Transformer, 25,000 Watts.

Evidently the best designed transformer must eventually fail to do its work properly if its insulation fails, and as transformers are usually subjected to the full influence of the weather, their deterioration in this respect is far more liable to ensue than is the case in well housed apparatus which can be inspected daily. In these days of increasing use of higher potentials also, thorough insulation is more than ever a *sine qua non*. The Stanley Company have therefore devoted special attention to the insulation of their new type of transformers. The primary and secondary coils form a perfectly solid mass, and are protected from contact with the iron core by a new method. A cross section of a coil has the appearance of a first-class submarine cable, being absolutely moisture-proof.

The accompanying engravings, Figs. 1, 2, 3 and 4 show a few of the sizes of transformers of the new type. The efficiency of these is very high, as attested by recent tests made by Prof. Harris J. Ryan, of Cornell University, an account of which was given in our columns a short time since.

Their efficiency varies at full load from 97½ to 98, dependent on the size, while at quarter load they still show the remarkably high efficiency of 96 per cent. to 85 per cent. The regulation also has been so well kept in hand that there is only a difference of 1½ volts out of 50 at the terminals of the secondary between no load and full load.

In a recent catalogue, the company draw an apt analogy between magnetic leakage and regulation, and the efficiency and life of incandescent lamps; both being in their way inter-dependent of one another. In other words, in straining to decrease leakage, regulation is impaired, and vice versa. There is a medium point between the two, which is the best to aim at.

The Stanley Co. have from the first been advocates of the employment of large transformers wherever they can be properly employed, in preference to a number of smaller ones of equivalent capacity, and in conformity with this opinion, they are actually manufacturing a transformer with a capacity of 25,000 watts or equivalent to 500 lamps. The arguments in favor of the employment of large transformers are almost self-evident. Not only is their first cost of like lamp capacity smaller than for an equivalent number of smaller transformers, but the operating expense is vastly inferior. This becomes manifest when we stop to consider the loss due to leakage current in a large number of smaller transformers as compared with that of a single large one, Taking for example the case of one 250-light transformer. It has a leakage current of .2 ampere as against 9 small transformers of an equal capacity having a leakage current of .6 ampere. There would thus be an economy of 66⅔ per cent. in the energy consumed on no load; besides it must be evident, that with a small number of converters the cost of inspection and maintenance is much reduced.

The Stanley Co. has also devoted special attention to "boosters" or converters designed to transmit current to very long distances, where potentials up to and above 5,000 volts are required for economy. In this way, by converting at a station from 1,000 volts to 5,000 volts, and re-converting in the outlying towns or factories down again to 1,000 volts, a second central station is as it were established at the other end of the line. A number of such converters have already been stalled with eminent success by the Stanley Co

Particular attention has also been devoted to the minor details, though not less important, namely, the arrangement of the fuses. This is shown in engraving, Fig. 5. In accordance with the more modern practice only the primary circuit is fused. The fuse is double-pole, each wire or link being carried on a separate porcelain plug or block. To replace the fuse, the door is dropped down by simply loosening one thumb screw, the plug pulled out and an extra one inserted from the new fuse attached to the same plug. The same size of porcelain plug is used in all sizes of transformers, all plugs being interchangeable.

As no screw drivers or pliers are required, all danger from shocks by the line-man is avoided, as he is required to handle nothing but a highly insulated porcelain block.

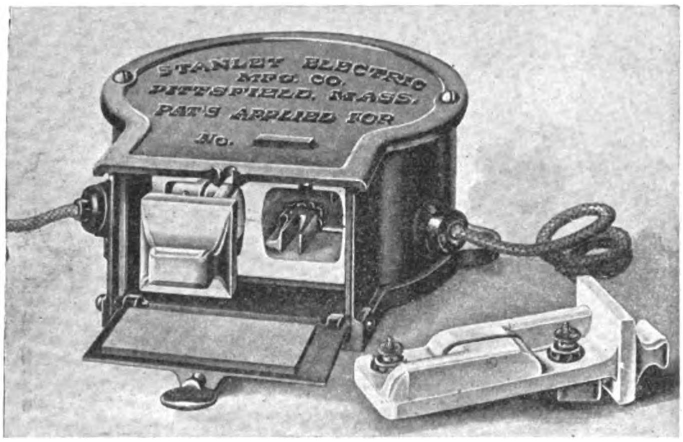

FIG. 5.—TRANSFORMER FUSE BOX.

The fuse-box inside of the iron is entirely of porcelain, thus making the whole fire-proof and the insulation perfect. The fuses are also entirely separated from each other by a porcelain partition, thus preventing arcing from one to the other.

Central station managers will, we are sure, find much to interest them in the new and highly artistic catalogue just issued by the Stanley Electric Manufacturing Company, of Pittsfield, Mass., from the press of E. E. Bartlett & Co.

ELECTRICAL ENGINEERING AT THE ARKANSAS STATE UNIVERSITY.

DURING the last year there has been established at the Arkansas State University a department of electrical engineering. The equipment as planned at present is designed to form the nucleus for further growth and enables the University to offer instruction in alternating and direct current, arc and incandescent systems, storage batteries, transmission of power and general experimental work.

The apparatus includes a 180-light Perret dynamo, two small Edison dynamos, a Westinghouse alternator, a six light Brush machine, a 10-h. p. Perret motor, a 3-h. p. Crocker-Wheeler motor and a few small machines built by the department. For experimental work there is available a 60-cell storage battery, Thomson balance and wattmeter, photometer, cradle dynamometer, Wheatstone bridge, Weston voltmeters and ammeters, magnetometers, Cardew voltmeter, eight galvanometers of various types, Wimshurst and Holtz machines, bank of incandescent lamps and large set of German silver resistance coils, so arranged as to carry dynamo currents, and to be free from the effects of self induction.

The course of instruction at the beginning of the junior year departs from that followed by the civil and mechanical engineers and offers work in the laboratory, in the elementary and more advanced theory of electricity, in electrical design, in specifications and contracts, and in the actual construction and operation of electrical machinery and apparatus.

The department is in charge of Prof. Harold B. Smith, a graduate of Cornell University, and associate member of the American Institute of Electrical Engineers.

INACCURATE REPRESENTATIONS OF THE WORLD'S FAIR ELECTRICAL FOUNTAINS.

WE have received the following important letter on the subject of the recent imaginative drawings that have appeared in one of our contemporaries, purporting to represent the World's Fair Electrical Fountains:—

To All who may be Interested:—

Reliable news regarding the progress of the plans for The World's Columbian Exposition is now of much importance to many electrical readers. The attempt of *The Electrical World* of this week to show in advance of the proper time of publication features which have not yet been decided upon regarding the proposed illuminated fountains, recalls a similar effort by the same paper less than three years ago.

At that time I sent to *The Electrical World* for publication the following letter, which never appeared in its columns:—

> 44 WALL STREET, NEW YORK CITY,
> June 25, 1890.
>
> Editor of THE ELECTRICAL WORLD.
>
> Dear Sir:—
>
> I am greatly interested in the sketch in your issue of this week of the "Proposed Edison Light Tower at the Minneapolis Exposition," more especially because, having the responsibility of designing and erecting this tower, I am still undecided as to nearly all the detail which your sketch purports to illustrate.
>
> I congratulate you upon the vividness of the imagination of your artist, and only regret that his idea and my own should have happened to be entirely dissimilar, and that his picture of this feature of the coming Exposition fails entirely to give your readers an adequate conception of the magnitude and beauty of the proposed structure and its surroundings.
>
> Yours very truly,

Both these unreliable batches of information came from the same source, the artist whose name appears on the illustrations. In the case of the Minneapolis Tower the disclosure was simply imaginative and premature; in the present case of the Chicago Fountains it is both imaginative and inaccurate and also a breach of faith. I presume it will be characterized as "newspaper enterprise"—the sort of enterprise that when it cannot print a genuine interview, prints an imaginary one.

I believe it was the celebrated A. Ward who once said "i had rather no nothing at all than to no what aint so."

L. STIERINGER,
Consulting Electrical Engineer,
World's Fair Chicago.

CHICAGO, Jan. 20, 1893.

LETTERS TO THE EDITOR.

IS STEINMETZ OR FARADAY RIGHT?

IN your issue of Jan. 11th I notice an article on the "Rotation of the Magnetic Field," by Mr. Chas. Steinmetz. This article is evidently intended as an answer to my criticism (p. 391 Vol. xiv) of his article (p 310 Vol. xiv) on "Twisting Magnetism." Mr. Steinmetz might have stated this fact without any fear of offending me, but as he did not, I have here done it for him.

Mr. Steinmetz states that "as long as the two characteristic quantities of the magnetic field, the intensity and the direction of the magnetic force, are constant in any point of space, the magnetic field must be said to be stationary and constant at this point of space." It is scarcely accurate to speak of direction as a quantity, but as the meaning of the sentence is clear and as I do not wish to be hypercritical I will let that pass.

I scarcely think, that Mr. Steinmetz meant what he wrote, as the words quoted are equivalent to saying that a uniform field of force must be fixed in space. For instance, assume a tangent galvanometer producing a magnetic field of sensible uniformity over a considerable space. Now suppose a small ring hung with its plane normal to the lines of force, from some fixed support outside the galvanometer. Next move the galvanometer in the plane of the ring, but not enough to bring the ring outside the uniform field. As the ring still encloses the same number of lines of force there has of course been no current or even E. M. F. induced in the ring.

According to Mr. Steinmetz the field of the galvanometer has not been moved; according to everyone else it has. But disregarding as he does, what everyone else says, I think that even Mr. Steinmetz will admit that when he carries a permanent magnet around in his pocket he also carries the field with it, whether the latter is uniform or not. If he does not he utterly deprives the term "field of force" of any intelligible meaning whatever. As the earth rotates upon its axis the imaginary lines called meridians rotate with it. We do not find the meridian of Greenwich for instance later in the day passing through New York and so on by the way of San Francisco and the Pacific Ocean back to Greenwich.

In the same sense in which the geographical meridians rotate with the earth, so do the magnetic meridians (neglecting the small diurnal variation); and so do the lines of force of every magnet, if the term "magnetic line of force" has as much meaning as the term "mathematical line."

TOWNSEND WOLCOTT.

NEW YORK, Jan 13, 1893.

LEGAL NOTES.

INCANDESCENT LAMP LITIGATION—HENRY GOEBEL, A NEW CLAIMANT FOR PRIORITY.

By Long Distance Telephone.

Boston, Jan. 23.—The columns of The Electrical Engineer last week contained a full and exclusive report of the interesting proceedings in Boston in the action brought before Judge Colt in the United States Circuit Court, by the General Electric Company against the Beacon Vacuum Pump and Electrical Company for alleged infringement of the Edison incandescent lamp patent. At that hearing, Monday, January 16, Mr. Witter, for the defence, obtained a delay of one week, in order that he might prepare and lay before the Court new evidence and an entirely new line of defence against any such action. The Court declined to enforce any sort of restraint against the defendant.

Pursuant to the adjournment for one week, until Monday, January 23, granted by Judge Colt, the case came up again for hearing to-day at 11 a. m. when Messrs. Witter and Brandeis again appeared for the defence, and Messrs. F. P. Fish, R. N. Dyer and C. A. Seward for the plaintiff. There were also in Court Mr. C. A. Terry, for the Westinghouse Electric and Manufacturing Company, with Messrs. Paul Cravath and Leonard Curtis; while Prof. Elihu Thomson and Mr. John Howell were in attendance on behalf of the General Electric Company.

Upon the opening of the Court, the plaintiffs asked for an adjournment of one hour in order that it might have time to examine a number of affidavits offered by the defence as the reason why no injunction of any kind should be issued against the Beacon Company. This adjournment was granted, and a recess was taken until 12 noon.

There were 28 affidavits, the more important of which ran as follows:

The affidavit of Heinrich or Henry Goebel, states that he is 74 years of age; was born in Germany, where he learned the trade of watchmaker and optician; was there thrown into association with one Prof. Moenighausen, a learned and ingenious man, for whom he made and repaired physical instruments; that this gentleman often talked with him about the possibility of making an electric light by means of a carbon conductor placed in a vacuum and heated to incandescence by the passage of a current. In 1848 he came to New York, and for more than 20 years carried on his business in Monroe street; in the early fifties he attempted to carry out some of the ideas of Prof. Moenighausen; he made a number of lamps of glass tubing having filaments of carbonized bamboo, and also of tampico; these were attached to wires of platinum, iron or copper, sealed air-tight into the tube by fusion; the air was exhausted by means of mercury and the lamp then hermetically sealed by fusion. From as early as 1855 to after 1881, he frequently made such lamps, and always had a number of them in his possession; often lighted his shop with them, with the aid of a battery of about 30 zinc-carbon cells; in 1859 and 1860 he was accustomed to exhibit in various public places in New York city, a large telescope mounted on a truck, through which he permitted people to look for a small fee; on this truck he had also a large battery and two or three of his incandescent lamps, which he was accustomed to light up to attract the attention of the passers by; these lamps were seen by a large number of persons, who well remember them. Some of these lamps have been preserved and accompany the affidavit.

The affidavit of John C. Goebel states that he is the eldest son of Henry Goebel and is an engineer; learned the machinist's trade from his father; remembers distinctly the electric lamps his father used to make in large quantities; often tended and lighted them himself; has a distinct recollection of having once looked at a picture in an illustrated newspaper of the shooting of Key by Sickles by the light of some of these lamps which stood on the show case in his father's shop (this event occurred Feb. 27, 1859); recognizes lamps shown him as exactly like his father's lamps; some of them had burners shaped like a fiddle-bow; others like a hair-pin and still others formed in a spiral; all were as small in cross section as the carbons of the lamps shown; remembers seeing his father make the spiral carbon by winding a very thin piece of wood around a cylinder, packing it in a crucible and putting the crucible in the fire. He remembers trouble his father had with employés of the gas company, who, seeing the electric lamps burning in the shop, accused him of having made a surreptitious connection with the gas mains. The light-giving portion of the lamps was always made of carbon, which his father called "coke;" the carbonizing was done in a range in the basement; he particularly remembers the use of a black lead crucible for this operation, because he used to wonder why, being lead, it did not melt in the fire; the wires passing through the glass were generally of platinum; sometimes of other metals; he bought little clippings and chips of platinum for this purpose because of their cheapness; does not remember how the air was removed from the lamps; does remember, however, that his father said there was no air in the lamps, and could not then understand how there could be space without air in it. He remembered his father's large telescope; sometimes exhibited it himself; there were at least three such lamps on the telescope wagon; had a great deal of trouble from slopping over of the batteries; one lamp, perhaps two, would burn while the wagon was going from Monroe street to Union Square; some of the lamps were destroyed as soon as the current was sent through them, but most of them were used repeatedly without apparent injury.

Henry Goebel, Jr., states that he is a son of Henry Goebel; has read his affidavit, and knows the electric lamps referred to therein; remembers seeing his father work upon and burn each of the three kinds of lamps mentioned by him, particularly the "hairpin" and "meat-saw" lamps. He frequently saw the lamps burning on the counter in his father's store, from his earliest remembrance; everybody could see them, and they attracted general attention. When a young boy he accompanied his father when exhibiting his large telescope in Union Square and other places, and remembers on a number of occasions hairpin and meat-saw lamps were burned just behind the driver's seat, partly to give light and partly to attract attention of passers by. Recognizes lamps shown him as some of those made by his father prior to 1872; the lamps did not burn long at a time because the batteries ran out; sometimes they would run half an hour or longer; many hundreds of persons must have seen the lamps burning on the wagon. Remembers his father thrashed him for breaking a meat-saw lamp the day he went to see his brother off who had enlisted in the navy during the war of the rebellion. All the lamps made by his father had the enclosing tube entirely of glass; the wires passed directly through the glass and had no solder or metal connection with the glass; the glass was fused directly round them and was fastened to the ends of two wires or ribbons, generally by stove-blacking. His father had a repeating clock fixed so that the mechanism would connect the circuit and light one of these lamps and illuminate the dial while the clock was striking; this was before and after 1872. In 1878 or '9 his father made a mercury vacuum pump which he used in exhausting lamps; he cannot remember any time prior to 1880, so long as six months at a time, when his father did not light up some of his lamps.

Horace E. Van Ranst, in his affidavit, states that he has been on the police force in New York for the past 32 years; knew Henry Goebel from about 1863 to 1872, when he was a watchmaker and optician; was frequently in his shop; he was a very sociable and interesting man, always experimenting and making something new. Remembers a large telescope that Goebel had mounted on a wagon, and behind the telescope on the wagon he had very brilliant lights which used to attract the attention of the crowd who followed the wagon; he also had some of these same lights in his store; remembers that the lighted part was enclosed in glass and that Goebel claimed that the light was produced by electricity, but does not recall having seen any batteries from which the electricity could come. Many people besides himself saw these lights; they were very remarkable lights and attracted a great deal of attention. Believes Mr. Goebel to be a man whose word could be thoroughly relied upon; he was a good-natured, reputable and reliable man, and was always experimenting; he once electroplated the buttons of his police uniform; he lived within two or three blocks of Goebel's shop.

Franklin L. Pope, makes affidavit that he is a solicitor of patents and expert; is familiar with the patents of Edison involved in the present litigation; has read the opinion of the Circuit Court of Appeals of October 4, 1892; understands the court to have held the then defendant to infringe the second claim of patent 223,898, that Edison's invention was practically made when he ascertained the hitherto unknown fact that carbon would withstand high temperature, even when very attenuated, if operated in a vacuum without the phenomenon of disintegration, and that Edison had utilized this fact by placing a filamentary carbon in a nearly perfect vacuum. The court had further said that no satisfactory evidence had been produced that the prior art had furnished any burners less than twice the size of that of the patent-office model of Edison's lamp. Deponent has examined the three exhibit lamps said to have been made by Goebel; neither of them is now in condition to be operated; but is entirely satisfied that when first made they were capable of such operation, and that they have at some time been so operated; each of these lamps originally consisted of a sealed chamber of glass within which was a carbon filament attached to metallic wires, which pass through and are sealed into the glass by fusion; the opening of the chamber has also been sealed by fusion; the light-giving portion of the filament in exhibit No. 3, is one and one-sixteenths inches long and from eight to ten one-thousandths of an inch thick; it is secured to the leading-in wires by indurated carbonaceous cement; the filament is made of carbonized woody fibre of endogenous growth, probably bamboo, the chamber is cracked and there is no vacuum in it now, but that there has been a vacuum in it is proved by the indentations at the top made by the pressure of the air when the glass was soft, and furthermore by the smoky discoloration on the inside of the glass which could only have been made by the vaporization of the carbon when in a state of incandescence. Deponent is clearly of the opinion that these structures embody the invention of the second claim of the patent in suit; moreover, the making and using of them necessarily involved a knowledge of the fact that a filamentary carbon would withstand high incandescence when placed in a nearly perfect vacuum. Referring to the affidavit of Goebel, in which he describes how he constructed his lamps, and how he obtained a supply of electricity for producing light, deponent is satisfied that it is entirely practicable to construct and operate such lamps with the methods and appliances which said Goebel states that he made use of, and that with equal care and skill in the manufacture that they would have a life commensurate with lamps made in accordance with the instructions laid down in the patent in suit. Some of the first lamps made by Edison lasted but a short time, but the long duration of some others demonstrated the correctness of the principle, and hence the question was how to make all the lamps last as long as the exceptional ones; this result has been secured by careful attention to all the details of manufacture.

PROF. CHARLES R. CROSS, of the Massachusetts Institute of Technology, makes an affidavit covering substantially the same ground as that of Mr. Pope, and confirming his opinions and deductions. He states that the cross-section of the carbonized filament of the Goebel lamp No. 3 was less than half that of the model accompanying the application for Edison's patent in suit.

NICHOLAS FINCK, in his affidavit, says he lives in Elizabeth, N. J., and keeps a jewelry store; is well acquainted with Goebel. Many years ago, about 1853, he made Goebel's acquaintance and was frequently in his store. Moved away from New York about 1855, and has since lived in Newark and Elizabeth. Has examined the exhibit lamps; has often seen such lamps in Goebel's possession and burning in his shop; can state positively that he saw such lamps before he left New York in 1855, and also since that time. Has frequently seen Goebel make the glass parts of these lamps; has seen him cut up the glass tubes and heat and work the glass; he used a bellows worked by the foot; there were two flames pointed towards each other with which he heated the glass. After the glass part was finished and the wires were in place inside, has seen him attach a long glass rod to the top of the lamp and fill the lamp and the rod with mercury and invert the lamp and let the mercury run out in a bowl; before the mercury had run out of the tube he would heat the tube near the top of the lamp and then twist it off so as to seal it tight; he said this was to get the air out of the lamp; asked him why he took the air out and he said that if any air was left in the lamp would be no good and wouldn't burn. He said the part which gave light was carbon and he made it; he showed him a crucible about six inches high in which he burnt the carbon. One evening saw him working with a piece of wood such as fishing-poles are made of, which he split up into pieces not thicker than fine wire or fine silk thread; saw a good many of these slivers before they were burned and afterwards; does not remember distinctly how the wires and the carbons were fastened together. Was concerned with Goebel in trying for eight or ten years to make something out of a patent for a hemmer which was granted in 1865, and this business led to his frequently seeing him at his place in New York; has no doubt from first to last, saw four or five different lamps before he left New York; sometimes they were used without any other light in the shop. Mr. Goebel was much discouraged by the constant trouble with the batteries. The shape of the carbons was sometimes straight and sometimes bent like a hairpin; the wires were attached to the ends of the hairpin. Mr. Goebel was a very ingenious man; made his own batteries, made his own tubes, carbonized the carbons and made the connections. Has no doubt Jacob Fey would remember the lamps; he was much about Goebel's store, and his statements may be relied on. Remembers taking his wife to Goebel's shop and showing her the lamps. Remembers the large telescope which Goebel used to exhibit at Union square, and that he had some of his lamps on the wagon that carried the telescope that were burned by batteries carried in the wagon; they were used to attract people to make use of the telescope.

JACOB FEY, of Brooklyn, makes affidavit that he is a native of Germany, a mason by trade, and came to New York in 1847; first knew Goebel in 1849; was often in his store in Monroe street; remembers well the little glass electric lamps which Goebel made and used; helped him make some of them; as many as fifty at least; Goebel used to heat the glass in a flame while deponent pressed the melted glass with pincers around the wires which went into the tube; would recognize the lamps if he saw them. Helped make some of them in 1852, and many more after he returned from Pennsylvania, which was in 1857. Has seen such lamps burning in Goebel's store hundreds of times; made a hole in Goebel's chimney before 1852 for him to put batteries in so that the fumes would go up the chimney. Helped Goebel to exhibit his big telescope once on Chatham square; has often seen the lamps burning on the wagon when the telescope was exhibited; identifies the lamps shown him as precisely like those he helped make; has seen Goebel take the air out of the lamps; he first filled them with quicksilver, then emptied them and sealed them by heating the glass; the lamps on the telescope wagon were to attract the attention of persons passing by and to induce them to look through the telescope.

GEORGE G. CROSBY makes affidavit that he was one of the organizers and general manager of the American Electric Light Company, formed about the beginning of 1881 for making and selling incandescent lamps; in March or April, 1881, learned that a man in New York named Goebel had an electric lamp and a vacuum pump, and was an expert in the manufacture of carbons and various physical instruments; sought him out and had a long conversation with him. Goebel showed deponent incandescent lamps which he said had been made a long time before, and that he had been making and using them constantly up to that time; he brought out a number of carbons, thirty or forty at least, which he had on hand; some of these were in the form of a loop; deponent took some of them home with him; they were from 2 to 3 inches long, thin and of very high resistance; they proved so much better than any the company had been able to make that they afterwards employed Goebel and his son to make carbons for them; but previous to thus employing him, he had made some lamps, glass and all, far superior to those the company had been making. Goebel had, when deponent first saw him, two vacuum pumps which he had made himself, and which were exceedingly good ones. Deponent at that time considered himself an expert in incandescent lamp matters, as in the early part of 1879 and until September, 1880, he had been employed in Edison's laboratory at Menlo Park, having while there worked under Edison's supervision upon carbons and vacuum apparatus. Deponent was impressed with and very much surprised at the knowledge possessed by Goebel, which was not only extensive, but surprisingly accurate. Deponent recognizes the lamps shown him as exactly like those shown him by Goebel at his first interview with him.

CELESTINE WEST, in her affidavit, says she is a daughter of Henry Goebel; recognizes the three lamps shown as precisely like those her father had as far back as she can remember, when he lived in Monroe street; has many times seen him make and use such lamps; most of them had straight carbons; some were hook-shaped but they were all thread-like, like the ones now shown her. Has often seen her father making lamps from glass tubing; remembers his carbonizing the thread-like part that gives the light, in a crucible in the fire. Does not remember seeing him extract the air from the lamps, but has heard him say there was no air in them. Remembers a lamp arranged to throw light on the face of a clock in his bedroom, which lighted up of itself whenever the clock struck. Remembers his large telescope on a wagon, and that he had some of the electric lamps on the wagon, but does not remember anything about the batteries; heard him speak about having them. Remembers having seen the lamps burning on the wagon a great many times as it started from the store, when going out in the evening for an exhibition.

MRS. NICHOLAS FINCK makes affidavit that she was married in 1858; that after her marriage and before the birth of her first child, which was in 1860, in company with her husband, she saw at Goebel's place several electric lamps; certainly more than two; they were lighted by electric batteries which her husband and Goebel explained to her; the lamps were little glass tubes, inside of which was a very slender piece which gave the light and which was connected by wires with the batteries; all the lamps were lighted; it was in the afternoon; never saw him make any of the lamps; never remembered seeing Goebel's lamps but that once, but has never seen incandescent lamps in recent years without recalling the fact that except the shape of the glass part they were just like the lamps in Goebel's shop. Remembers looking through Goebel's large telescope in Union square in the evening, and that the wagon was lighted; did not remember by what means. Is now shown for the first time the three exhibit lamps; they might be the very lamps she saw; can discover no difference in them. The light-giving part looked like a very fine wire white hot, and as she remembers it, not thicker than a thread. The light-giving part of lamps of to-day is in the form of a loop, but that of Goebel's lamps was straight; told Mr. Goebel it was a beautiful light and that he ought to get rich out of it; has never forgotten the effect which these lamps produced upon her mind.

A considerable number of affidavits were produced from old residents of that section of New York City where Goebel lived at the time he is alleged to have made and exhibited his telescope and his electric lamps. Most of these persons state that they have known Goebel from 30 to 40 years, that they frequently saw his lamps burning, both in his store and on his telescope wagon, and are able to describe them with considerable accuracy and to identify the exhibits. Many of them testify to his good character. The names of some of these witnesses are as follows:

John J. Benson, Alexander McArthur, James Benson, William Nethercott, William Whikehart, Thomas Conroy, James F. Conerty, William Harrigan (of Harrigan & Hart), John Galvin.

There were other affidavits also from Julia Zoller, E. Seger, E. Brush, G. Linder, W. Newman, T. F. Brady, H. J. Schwallenberg, and H. S. Kaliske, of the Beacon Co.

Upon the reassembling of the court, **MR. FISH** said they were ready to take the thing up now.

MR. DYER made a vigorous plea for an immediate injunction, pooh-poohing this mass of affidavits which had been presented showing a prior use in public of the carbon filament lamp 30 years back. He laid great emphasis on the improbability of the story amounting to anything, in view of the fact that it was claimed that the prior invention had been known to so many people in New York city. Had that been so it would have come out long before. Again, these affidavits set forth that Goebel, the claimant for priority, had been in the employ of the American Company in 1882. That old company was practically a part and parcel of the infringers against whom an injunction had already been secured, as it had become one with the Sawyer-Man, Consolidated, and Westinghouse interests. That being so, those defendants against whom they had already secured judgment must have known all about this thing, and yet they never produced it—which was significant. Mr. Dyer said they would be prepared to prove also that those defendants had been in possession of the Goebel matter for some months back, but had not found it desirable to try to use it.

Mr. Fish said that he would later in the day produce in court two affidavits, then being prepared, which would be offered in rebuttal of this mass of affidavits offered for the defence.

After the lunch recess, Mr. Dyer again made an urgent request for an immediate injunction, waiving aside as immaterial and as unworthy of further investigation this alleged prior use.

Mr. Witter, however, followed immediately in a long and able speech, which lasted about 1½ hours and was not concluded at the close of the day. He read long portions of the affidavit of Henry Goebel, the claimant for priority, and commented upon them very fully. This was the only affidavit taken up and discussed out of the twenty-eight presented before the Court and open for inspection. Mr. Witter urged the entire probability of Goebel's story.

The Court adjourned at 4.05 p. m. to reassemble at 10 a. m. on Tuesday.

G. M. P.

THE MANUFACTURE OF ALUMINUM.—DECISION IN FAVOR OF THE PITTSBURGH REDUCTION COMPANY.

The suit between the Pittsburgh Reduction Company, of Pittsburgh, Pa., and the Cowles Electric Smelting and Aluminum Company, of Lockport, N. Y. and Cleveland, Ohio, for infringement, was decided in favor of the plaintiffs, the Pittsburgh Reduction Company, on January 11, by Judges Ricks and Taft, of the U. S. Circuit Court for the Northern District of Ohio. The decision was a sweeping one, inasmuch as the Hall patent for the reduction of pure aluminum by electrolysis was sustained on every point. This gives the Pittsburgh Company a practical monopoly of the entire aluminum business of this country, as it is the only process used to-day in this country or abroad for the reduction of that metal. The suit has been going on for the last two years and the testimony covered 2,000 closely printed pages. The principal experts on the plaintiff's side were Prof. Charles F. Chandler, of Columbia College, N. Y.; Prof. John M. Langley, of the Case School of Applied Sciences, Cleveland, Ohio; Dr. Rossiter W. Raymond, expert metallurgist, and Secretary of the American Institute of Mining Engineers; and Mr. Charles M. Hall, the inventor of the process.

Mr. Hall, the inventor, is a very young man, being a graduate of the class of '84 in Oberlin University, where he conceived his process before his graduation. The invention consists in the reduction of the ore of aluminum, alumina, which is an oxide, by dissolving it in a fused mass of fluoride of aluminum, together with a fluoride of some other metal more electro-positive than aluminum, and precipitating the metallic aluminum from the dissolved alumina by means of electrolysis. The dissolving fluoride bath remains practically constant, and the process is a continuous one, for the reason that the ore is simply dumped into the bath, when the precipitation immediately begins, and the metal is either tapped out, or ladled out without interruption whatever. By it aluminum of exceptional purity has been brought from $12.00 a pound to 50 cents a pound, which, figured bulk for bulk, is as cheap as copper, and cheaper than tin or nickel. By the very careful estimates made by experts it is thought that by further refinements of this process aluminum can be produced on a scale of two or three tons a day at a cost of something like 17 cents a pound, which, bulk for bulk, is as cheap as zinc or lead.

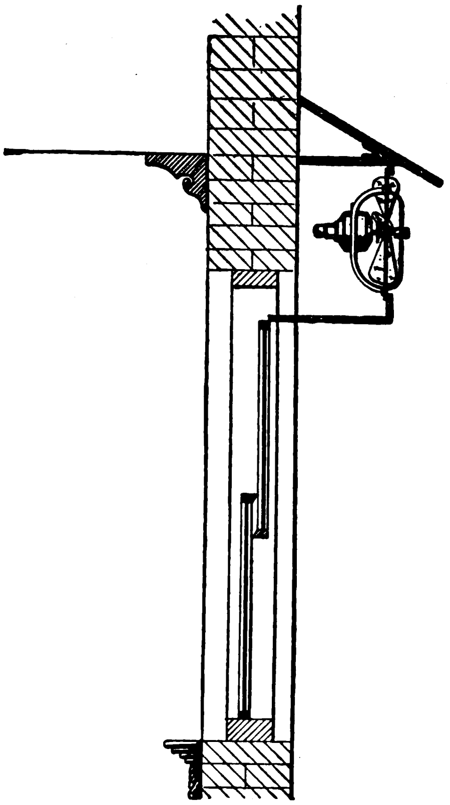
The attorneys for the plaintiffs in the case were George H. Christy and Thomas W. Bakewell, of Pittsburgh.

It may be added that in 1886, Hall had an interference suit with Heroult, who has large aluminum works, near Schaffhausen on the Rhine, Switzerland. The suit lasted a year and Hall was adjudged the prior inventor. The point at issue was one of those raised in the present suit and again decided in favor of Hall.

Pettingell-Andrews Co., the well known Boston electrical supply house, have been given the large and important New England agency for the Siemens & Halske Electric Co. of America. They will handle all the various classes of Siemens & Halske apparatus. The agency could not be in better hands.

VENTILATING A CLUB BILLIARD ROOM.

The present winter has put to a very severe test the ventilation of many rooms and halls which were supposed to be modern in every hygienic respect. When the cold is as rigorous as it has been the last month or two, the temptation to keep all the doors and windows closed can hardly be overcome. Heat units are doubly valuable, and the blast from the window or draughts from the door are so icy that nobody encounters them willingly. As a consequence, rooms remain either very chilly or seriously overheated; and this is true of many pretentious dwellings and handsome clubs and hotels. A study of this situation has led Mr. E. W. Little, of the Interior Conduit & Insulation Company, to hit upon a highly simple yet effective solution of the difficulty, and it is illustrated in this article. The special problem was the ventilation of the billiard room of the New York Clubhouse, on Fifth avenue. Mr. Little and other players there experienced annoyance as much, perhaps, from the heavy clouds of tobacco smoke as from the heat; and ordinary methods of "ventilating" only added to the discomfort. Mr. Little has therefore rigged up at an open window one of the Lundell globe motors attached to a small Blackman ventilating fan. The motor stands in a neat little box, with pent roof, just outside the slightly lowered window, and hence there is no interference with the window or sash proper. The motor is controlled by a switch in the room, and the sash itself can be raised or lowered at any time except that at which the fan happens to be running. A very little work of the fan will clear and purify the air, and yet there is no sudden indraught of cold air from any point; and the motor can be stopped whenever it has done its work.



Ventilating with Lundell Motor and Blackman Fan.

The success of this handy little outfit has suggested its application elsewhere, for summer and winter alike; and the Lundell motor, with ventilating fan is thus beginning to occupy a new field of usefulness. The motor and exhaust fan are supplied in various sizes, for the various currents, and with the due complement of starting and regulating boxes. The combination, and its method of application, are among the most ingenious things we have seen of late.

ELECTRIC RAILWAY GROWTH.

The General Electric Company reports the sale of one-fifth as many railway motors in one week in January as during the whole year of 1892. There are now 277 street railways in the United States, using an aggregate of 5,774 Thomson-Houston motor cars, and on January 15, 1892, there were only 180 street railways using 2,790 Thomson-Houston motor cars. This makes 2,984 Thomson-Houston motor cars sold from the street railway department, or an aggregate business of about $5,968,000 last year for motors alone.

IMPORTANT MEETING OF THE ADVISORY COUNCIL OF THE CHICAGO ELECTRICAL CONGRESS.

A MEETING of the Advisory Council of the Chicago World's Congress of Electricians was held at the rooms of the American Institute of Electrical Engineers, New York, on Jan. 17th.

The following gentlemen were present: Dr. Elisha Gray, Chairman, Prof. Wm. A. Anthony, Prof. Chas. R. Cross, Dr. Louis Duncan, Dr. Wm. Geyer, Mr. Carl Hering, Mr. Geo. A. Hamilton, Prof. F. B. Crocker, Mr. A. E. Kennelly, Mr. T. D. Lockwood, Mr. T. C. Martin, Mr. Geo. M. Phelps, Dr. M. I. Pupin, Mr. R. W. Pope, Prof. H. A. Rowland, Mr. Herbert Laws Webb.

Mr. H. L. Webb was elected Secretary of the meeting, in the absence of Prof. Carhart, permanent Secretary of the Council. The preliminary reports of the English and American Committees, already made public, were received.

It was resolved that the Electrical Congress of 1893 shall consist of two Chambers, of which the Legislative Chamber shall decide on units, names of units, and standards, and shall consist solely of delegates named by their respective Governments.

A Committee was appointed to determine the total number of official delegates and their apportionment to the various countries to be represented.

The following apportionment of delegates was made by the Committee whose report was adopted by the meeting. Great Britain 5, France 5, Germany 5, Austro-Hungary 5, United States 5, Belgium 3, Italy 3, Switzerland 3, Holland 2, Denmark 2, Norway and Sweden 2, Russia 2, Spain 2, Portugal 1, British North America 1, Australian Colonies 1, India 1, Japan 1, China 1, Mexico 1, Brazil 1, Chili 1, Peru 1, Argentine Republic 1; making a total of 55 official delegates.

It was resolved that a Committee on Invitations be appointed by the Chairman, this Committee to consist of 5 members who shall select and recommend to the Chairman the names of electricians, electrical engineers and others who shall be members of the Electrical Congress. Said Committee to co-operate with the foreign Committees.

It was further resolved that in addition to invitations to deliberating and voting members of the Congress, a general invitation shall be extended through the journals or otherwise that the meetings will open to the public, for attending the proceedings, but not for taking part therein.

It was resolved that a Committee on Programme and Papers be appointed by the Chairman. This Committee shall consist of eight members, whose duty it shall be to invite, receive and consider papers and other documents relating to the work to be done by the Congress. And it was further resolved that it shall be the duty of this Committee to formulate a programme for the Congress.

It was resolved that the reports of the English and American Sub-Committees which were received at the meeting should be referred to the Committee on Programme and Papers, and that the Committee confer with the English Committee as fully as possible and with such other foreign Committees as may be formed.

It was resolved that the Electrical Congress of 1893 shall last one week, beginning on August 21st.

It was resolved that a Committee of three be appointed by the Chairman as a Finance Committe.

It was resolved that an Executive Committe of five shall be appointed by the Chairman, said Committe to have full power to act for the Advisory Council.

It was resolved that the question of charging a fee for membership of the Congress, and fixing the amount of such fee be referred to the Executive Committee.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 10, 1893.

Alarms and Signals :—

Railway Signal, W. F. Z. Desant, New York, 489,629. Filed Apr. 25, 1892.
An electrically operated semaphore.

Railway Signal, J. E. Geary, Syracuse, N. Y., 489,736. Filed Dec. 29, 1891.
An electric block system for steam railways.

Distribution :—

Electric Lighting System, F. B. Badt, Chicago, Ill., 489,598. Filed Oct. 22, 1892.
Employs a group of incandescent lamps, the filaments of which are connected in series, and conductors leading each from one main line conductor to a point in the series circuit between a pair of lamps.

Dynamos and Motors :—

Means for Controlling Electric Motors, J. F. Ott and A. E. Kennelly, Orange, N. J. 489,687. Filed May 7, 1891.
Provides means by which the motor can be controlled in a safe and efficient manner from either end of the car.

Variable Speed Electric Motor, C. Hering, Philadelphia, Pa., 489,709. Filed Apr. 30, 1892.
Claim 1 follows:
A duplex electric motor consisting of two electric motors both having the usual parts, namely, an armature and a field, one of which parts is fixed, two of which revolve and are mechanically coupled, and the fourth of which is capable of revolving and is connected to the work.

Galvanic and Thermo-Electric Batteries :—

Galvanic Battery, W. C. Cahall, Philadelphia, Pa., 489,522. Filed Sept. 29, 1891.
Employs a plate composed of the oxide of antimony intimately combined with carbon.

Galvanic Battery, G. L. Foote, Brooklyn, N. Y., 489.559. Filed Sept. 13, 1892.
Employs a rotatable zinc electrode with a stationary scraping device arranged below it.

Electric Battery, C. H. Bryan, Chicago, Ill., 489,668. Filed May 3, 1892.
A dry battery exciting compound comprising a mixture of salt of calcium, a ferrous salt and a salt of mercury.

Galvanic Battery, W. R. Reud, New York, 489,832. Filed June 23, 1892.
Claim 1 follows:
A galvanic battery of cylindrical shape having concentric poles and a ball secured to one end of the battery.

Lamps and Appurtenances :—

Electric Lighting System, H. M. Doubleday, Pittsburgh, Pa., 489,526. Filed Apr. 21, 1892.
Employs a reactive coil carried by the fixture or chandelier and two or more incandescent lamps with multiple point switch devices and circuit connections to different points in the length of the reactive coil.

Lamp Socket. A. Metzger, Schenectady, N. Y., 589,682. Filed Apr. 26, 1892.
A socket having an insulating body with an extension on which the terminals are mounted.

Socket Switch for Incandescent Electric Lamps, L. Henry and L. N. Dalysson, Newark, N. J., 489,739. Filed Oct 10, 1892
Provides means whereby the current may be turned on by pressing a button and turned off again by pressing the same button.

Hanger for Electric Lamps, C. S. Hume, Detroit, Mich., 489,815. Filed June 2, 1892.

Miscellaneous :—

Automatic Feed and Return Mechanism for Phonographs, M. O. Anthony, Cincinnati, O., 489,519. Filed Nov. 20, 1890.

Electrical Diaphragm, C. N. Waite, Newton, Mass., 489,551. Filed March 16, 1892.
A layer of acid resisting fibrous material and bi-chromatized gelatine.

Electric Gas Lighting Apparatus, A. M. Sloss, Kansas City, Mo., 489,616. Filed March 24, 1892.

Electrically Controlled Ventilator, S. G. Brinkman, New York, 489,625. Filed March 3, 1892.

Electric Gas Lighter, T. W. Lane, Boston, Mass, 489,653. Filed Jan. 25, 1892.

Bracket for Electric Light Wires, G. H. Bennett, Cincinnati, O., 489,861, Filed Nov. 16, 1891.

Electric Prison Cell and Guard, W. S. Hull, Sheffield, Ala., 489,902. Filed Sept. 22, 1891.

Railways and Appliances :—

Electric Railway Trolley, E. H. Jenkins, Winfield, Md 489,481. Filed July 20, 1892.
Invention consists of a longitudinally movable bracket evenly supported upon the end of the trolley pole and carrying the trolley wheel.

Electric Railway, D. E. Kimball, Topeka, Kans., 489,563. Filed Jan. 11, 1892.
Employs main and sectional conductors, a series of rock shafts, and switches between the conductors operated by the rock shafts, and a device carried by the car to close the switches when the car is passing.

Conductor System for Electric Railways, G. W. Von Siemens, Berlin, Germany, 489,573. Filed Feb. 3, 1891.
Employs a contact conductor composed of a series of relatively-insulated sections with normally-interrupted connections between it and the supply conductor; an electromagnetic device for each contact section and armatures adapted to be successively operated by a magnetic device on the vehicle, to close the circuit and complete the interrupted supply connections of the section into which the vehicle is moving.

Multiphase Railway System. F. B. Badt, Chicago, Ill., 489,597. Filed Feb. 19, 1892.
Claim 7 follows:
The combination of a movable car with means for leading from an insulated conductor a multiphase current thereto, a multiphase motor transformer on such car, a storage device to receive from such motor transformer and a switch to control connections from the insulated cable to the car, said switch responsive to a current delivered from such storage device.

Strain Insulator, Louis McCarthy, Boston, Mass., 489,658. Filed June 29, 1892.

Telephones and Apparatus :—

Spring Jack Switch, C. E. Scribner, Chicago, Ill., 489,570. Filed Dec. 27, 1880.
Employs a main lever and a yielding contact against which it normally presses, and a stop for limiting the movement of the contact toward the spring.

Spring Jack Switch for Telephone Exchanges, C. E. Scribner & W. R. Patterson, Chicago, Ill., 489,571. Filed Jan. 21, 1892.
Employs a pair of flat springs insulated from one another by a strip of rubber.

Attachment for Telephones, J. L. Davidson, Pittsburgh, Pa., 489,608. Filed Oct. 8, 1892.
A writing desk attachment for telephone wall sets.

Underground Electric Railway, J. B. Sheldon, D J. Murnane and G. L. Van-Beek, St. Louis, Mo., 489,764. Filed June 22, 1891.
Employs a main supply conductor, a pivoted switch provided with an exposed flexible contact, and consisting of a hermetically-sealed box with contacts located therein so arranged that when the switch is actuated the exposed contact is thrown into electrical connection with the supply conductor.

Closed Conduit Electric Railway, C. A. Stark, Duluth, Minn., 489,835. Filed Mar. 23, 1892.
Claim 1 follows:
An electric railway, comprising a surface conductor, a line wire held in a conduit adjacent to the surface conductor and adapted to connect therewith, a compressible rail, and means for closing the circuit through the surface conductor by the movement of the rail.

Electric Car Truck, T. Tripp, Avon, Mass., 489,883. Filed June 30, 1892.
Claim 4 follows:
In an electric vehicle, the combination of an axle, loose wheels adapted to rotate on said axle, an electric motor having two independently rotatable armature shafts disposed in endwise relation to each other, and connecting mechanism between said loose wheels and said shafts.

Switches and Cut-Outs :—

Electrical Switch, G. Baehr, Brooklyn, N. Y., 489,553. Filed Mar. 26, 1892.
A quick-acting double-blade snap switch.

Loop Switch, F. D'A. Gould, Schenectady, N. Y., 489,674. Filed April 15, 1892.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

GENERAL ELECTRIC PLANT IN THE INDIANA HOSPITAL FOR THE INSANE.

It is a rule to which we find but few exceptions, that when state and city governments undertake the construction and fitting up of establishments under their own immediate supervision, the work is excellently well done with material of the best, little expense being spared to make the job a credit. The electric installation by the Indiana state government in the Central Indiana Hospital for the Insane, at Indianapolis, is no exception to this rule. The establishment is one of unusual size, and the installation can be considered as one of the largest isolated plants in the country. The large building is divided into two separate departments, and the power and steam plants are both located in a small building 200 feet in the rear of the centre of the main buildings.

The generating plant consists of three 45 K. W. and two 25 K. W. compound wound General Electric Company's dynamos for direct incandescent lighting, and one 10 K. W. 30-light arc dynamo each directly connected to a high-speed engine of the Phœnix type drawing steam from three 125 h. p. boilers installed by the Phœnix Iron Works.

Three separate feeders of lead-covered cable, laid underground in water-tight boxes of 2-inch plank painted with insulating paint, run from the power-house to each main building. Each wire lies loosely in its place so that they can be drawn in or out at any time. Socket-bolted terminals are used where the underground cables connect to feeders in the basement and can be readily disconnected for testing purposes. Rubber-covered wires are carried from the feeders to the attic, and the current is fed from the attic down to the other floors.

The three feeders which run to the Women's Department supply three separate systems; feeder No. 1 furnishes current for 12 wards south from the grand centre of the building; feeder No. 2 supplies 11 wards north of the grand centre; feeder No. 3 supplies the grand centre itself, in which are the executive offices, and the rear centre comprising chapel, bakery, kitchen, etc. This last is an all-night circuit, controlled by a switch in the superintendent's office. A similar switch controls the all-night circuit in the sick ward, 600 feet north from the centre.

The wiring of an insane asylum differs materially from that of other institutions, not subjected to the peculiar conditions presented. In this case the wires are all run in moulding with backing, and the cabinet-cut-out boxes are set back in the brick walls. The covers are heavily-raised panels of extra strength so that they cannot be broken by the patients. Each cut-out box is furnished with a Yale lock, and each ward has its own cut-out box controlling from 20 to 65 lights.

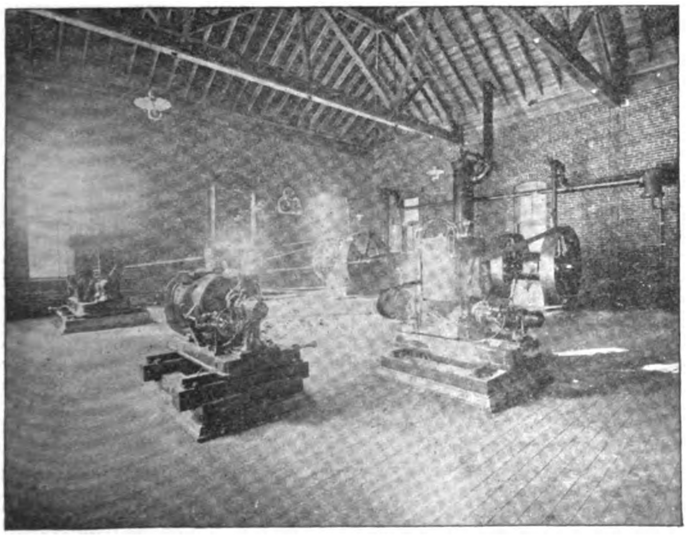


Fig. 1.—Dynamo Plant, Indiana Hospital for the Insane.

The 2,200 lights on the system are controlled by switches, and each switch, whatever its capacity, when operated controls an equal number of lights on each side of the neutral, with 110 volts only on each switch, so that overbalancing of the system is obviated.

All lights are thrown off at the power-house at 10 o'clock at night, with the exception of those in the sick wards and superintendent's quarters. A special switch changes the system from three-wire to two-wire at 10 o'clock, the smallest engine sufficing to operate the incandescent and arc dynamos after that time until morning. This switch is so connected that one, two or three dynamos can be thrown into multiple on the two wire system, together or separately.

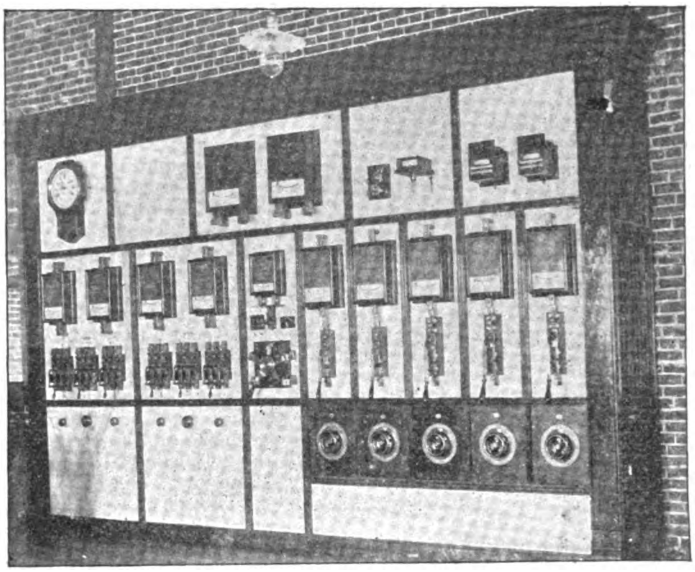

Fig. 2.—Switchboard, Indiana Hospital for the Insane.

There is 70 000 feet of moulding, from 1¼ inch to 5½ inch used on this installation. The lamps are suspended by flexible-cord pendants with key-sockets and porcelain cut-outs.

The arc circuit is used to illuminate the grounds. Two miles of General Electric lead-covered cable laid undergound in iron pipe, carries the current to the twenty 1,200 c. p. lamps suspended from 25-foot ornamental poles, well stepped.

The cable runs from lamp to lamp without splices. At the bases of each pole, and four inches below the surface is set a junction box 18 inches square.

The accompanying illustrations Figs. 1 and 2, show the dynamo-room and the switchboard respectively. The entire system is laid out with material of heavy enough capacity to carry 3,300 16 c. p. incandescent lamps, as well as the arc lamps. The installation was effected by the Chicago office of the General Electric Company and is pronounced by the trustees to be alike a "credit to the company and the state."

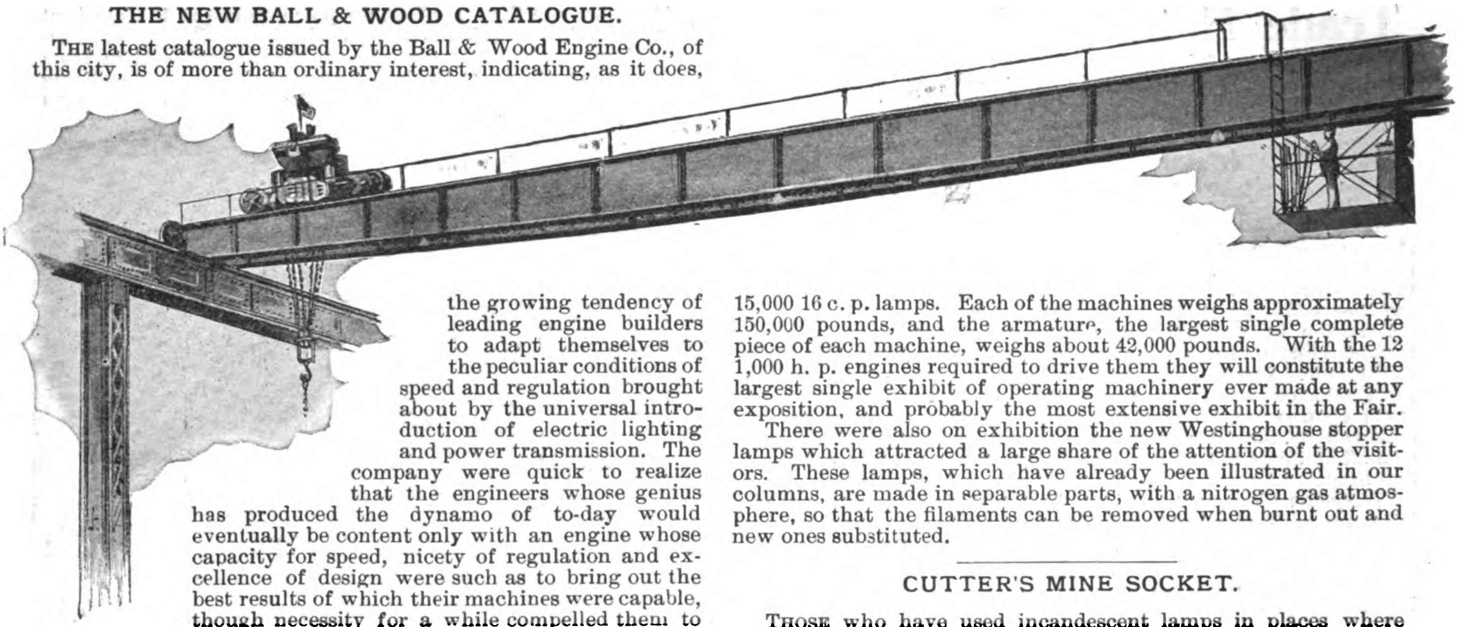
TERMINAL CHARGES AT THE FAIR.

The Traffic Department of the World's Fair has issued a memorandum to exhibitors and transportation companies containing the latest regulations concerning the charges for the reception and handling of exhibits on the exposition grounds. It is announced that the exposition will make a terminal charge of six cents per 100 pounds, with a minimum charge of 50 cents for any single shipment. Extra charges will be made for handling exhibits over 30,000 pounds in weight, and arrangements for the reception of such exhibits must be made in advance with the transportation manager. A charge of $5 per car will be made on all exhibits which arrive on their own wheels, such as palace cars to be exhibited in the Transportation Building, and $10 for locomotives arriving with their tenders. These charges will be made in each direction.

"WORTH FIVE TIMES ITS PRICE."

A reader in the South, electrician to a railroad company, writes us in renewing his subscription :—"Please let me say here that I would not be without The Electrical Engineer for five times the subscription price. Whenever I require anything (which is frequent) I can always tell where to send for it by looking over the advertising columns of The Engineer, and it has given me a vast amount of information. I say, long live The Electrical Engineer, and wish you every success."

THE NEW BALL & WOOD CATALOGUE.



THE latest catalogue issued by the Ball & Wood Engine Co., of this city, is of more than ordinary interest, indicating, as it does, the growing tendency of leading engine builders to adapt themselves to the peculiar conditions of speed and regulation brought about by the universal introduction of electric lighting and power transmission. The company were quick to realize that the engineers whose genius has produced the dynamo of to-day would eventually be content only with an engine whose capacity for speed, nicety of regulation and excellence of design were such as to bring out the best results of which their machines were capable, though necessity for a while compelled them to accept what was already at hand. Events have proved the accuracy of their foresight; to quote the language of the catalogue before us: "Perhaps there has never been witnessed a more striking instance of two mechanisms advancing hand in hand than this of the modern dynamo and the modern high speed engine."

It is of the merits of this engine, as designed by the Ball & Wood company, that the pamphlet treats. Simple, tandem and cross compound types, together with their separate parts in detail, form subjects for a set of illustrations that are masterpieces of the engraver's skill in this difficult class of work. The catalogue is further embellished with a number of artistic little wash drawings daintily executed and cleverly placed, and is bound in an embossed cover of electric blue bearing in relief the name of the company surrounded by a graceful design.

The catalogue is from the establishment of Messrs. E. E. Bartlett & Co., and is executed with all their customary artistic design and finish.

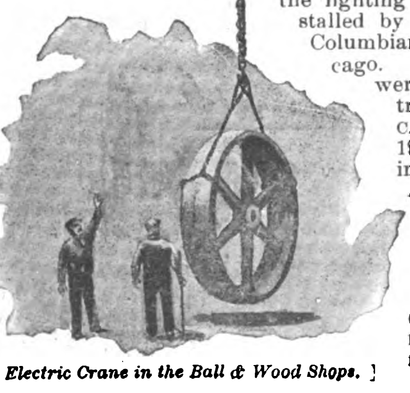
THE PERU, IND., ELECTRIC MANUFACTURING CO.

THE PERU GLASS AND CARBON COMPANY and Peru Porcelain Works (associated) have been succeeded by the Peru Electric Manufacturing Company, incorporated with capital stock of $100,000, and all accounts, both payable and receivable, have been assumed by the Peru Electric Manufacturing Company.

The new company have purchased the factories known as the "Dow Plant," regarded as one of the finest plants in the State and expect to occupy their new headquarters about the first of the coming year, when their products will be doubled, and with better accommodations more prompt service can be guaranteed. The officers of the new company are J. O. Cole, president; P. C. Burns, vice-president; S. F. Porter, treasurer and manager; R. H. Bologne, secretary; who are also directors with Milton Shirk, R. A. Edwards, and C. H. Brownell. The company will make, as before, but on a larger and more varied scale, carbons, carbon batteries, switches, sockets, rosettes, cut-outs, insulators and general electrical supplies.

THE WESTINGHOUSE WORLD'S FAIR EXHIBIT.

AT the invitation of The Westinghouse Electric and Manufacturing Company, a large number of visitors were afforded last week an opportunity of inspecting the lighting machinery to be installed by the company in the Columbian Exposition at Chicago. The dynamos which were described and illustrated in THE ELECTRICAL ENGINEER of Oct. 19, 1892, are now nearing completion in the Allegheny City Works of the Westinghouse Company, and are among the largest machines of their kind ever constructed. They are 12 in number, each with a maximum capacity of 15,000 16 c. p. lamps. Each of the machines weighs approximately 150,000 pounds, and the armature, the largest single complete piece of each machine, weighs about 42,000 pounds. With the 12 1,000 h. p. engines required to drive them they will constitute the largest single exhibit of operating machinery ever made at any exposition, and probably the most extensive exhibit in the Fair.

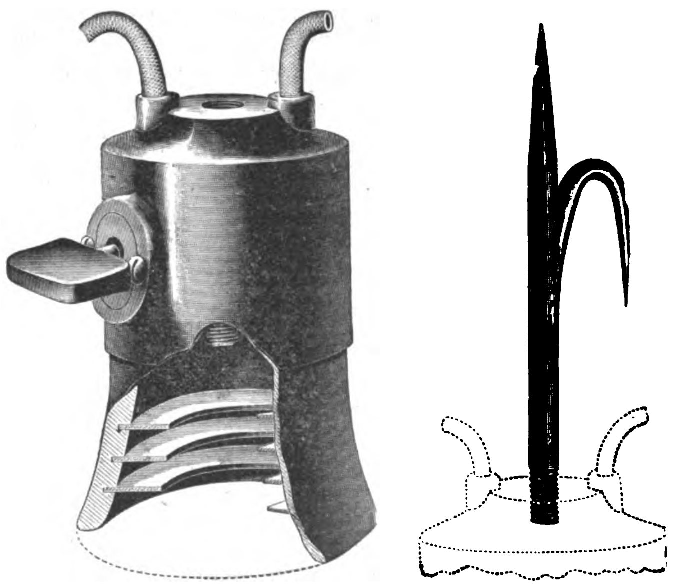


Electric Crane in the Ball & Wood Shops.

There were also on exhibition the new Westinghouse stopper lamps which attracted a large share of the attention of the visitors. These lamps, which have already been illustrated in our columns, are made in separable parts, with a nitrogen gas atmosphere, so that the filaments can be removed when burnt out and new ones substituted.

CUTTER'S MINE SOCKET.

THOSE who have used incandescent lamps in places where water is apt to run over them know how some so called waterproof sockets fall short of the mark. They apparently shield the works of the socket from the dripping water, but do not prevent the moisture from creeping up on the lamp and short-circuiting the cap. The result is that the fuses are blown much too often, thus leaving the men in darkness unless they have other lamps at hand.



CUTTER'S MINE SOCKET.

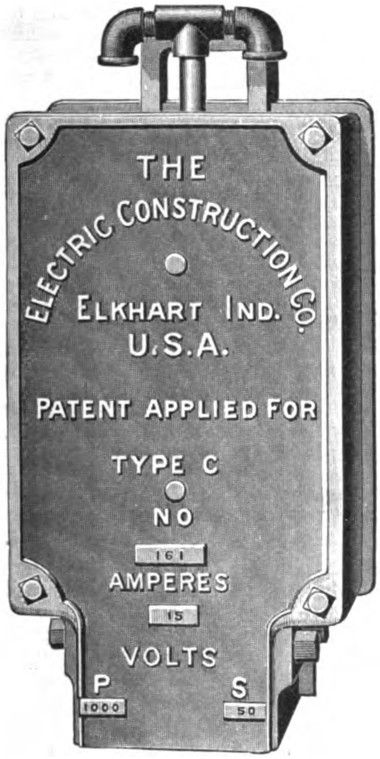
These defects in the ordinary rubber, glass or porcelain sockets have been considered by George Cutter, of Chicago, in developing the socket shown in the accompanying illustration. This has a well built interior (with porcelain insulations) protected by a casing of polished hard rubber. The leading in wires are cemented into the shell, while the handle or key passes through a bushing which is made watertight by soft rubber washers. These prevent any moisture from entering the shell at the sides so that the only danger is from the creeping of the water along the bulb of the lamp. To avoid this, the shell has a series of soft rubber rings which press against the bulb of the lamp when screwed into place and prevent any moisture from reaching the lamp base. It is said that such a socket can be used with safety in places where there is a steady dripping of water, and that it can be entirely immersed without any danger from short-circuits. When used in mines, it is furnished with a prong, as shown, so that it can be hooked in any convenient position.

THE SHULTZ BELTING CO., of St. Louis, have just taken an order from a Cleveland, O., concern for an 80 inch wide belt, which will be, it is said, the largest of its kind ever made in the world. It will be manufactured from Shultz patent sable raw hide.

THE ELKHART CONVERTER.

The Elkhart Converter which has been prominently set forth in our advertising columns for some time is being exploited in the West by the Electric Appliance Company, of Chicago, and is deserving of some special mention.

The general appearance of the apparatus is shown in the accompanying illustration. The case, as is customary, is an iron waterproof shell constructed with a view to the least possible weight consistent with the necessary strength.



The Elkhart Converter.

Its special feature however is, of course, its electrical construction. The coils are wound in an oblong coil extending the full length of the case, the secondary being first wound on a form and the primary wound over and upon the secondary. The iron is then built up inside and around the coils, the laminations being arranged in such a way that the joints are broken or staggered in every layer; *i. e.*, the joints do not come in the same place in any adjacent laminations. The result thus attained is that the coils are surrounded entirely by iron, making the converter almost a solid mass of iron, but at the same time broken up in a way that effectively prevents hysteresis, heating and magnetic loss. The converters are placed in neat, iron weatherproof cases ready to install as shown in the cut. The arrangement for fuses is of special construction, being a porcelain block with removable fuse cap, thus allowing fuses to be replaced with perfect safety.

SALES OF SIEMENS & HALSKE APPARATUS.

Mr. J. Holt Gates, General Sales Agent of the Siemens & Halske Electric Company of America, reports the following sales of electrical apparatus to January 1, 1893:

Pabst Heat, Light and Power Company, Milwaukee, two direct coupled multipolars of 250 h. p. each, speed 214 R. P. M., also one of 100 h. p., speed 277. Auditorium Hotel, Chicago, two 450's, speed 158; two of 300 h. p., speed 214; two of 150 h. p., speed 227. Broadway Power House, New York, two of 80 K. W. capacity, speed 235; one of 40 K. W., speed 300. Betz Building, Philadelphia, two of 80 K. W., speed 250; one of 40 K. W., speed 290. New Era Building, Chicago, two of 90 h. p., speed 360. Bauerle & Stark, Chicago, one 50 h. p. Co-operative Electric Light and Power Company, Chicago, two direct coupled alternating dynamos 600 h. p. each, speed 100 revolutions each. Buffalo Bill's Wild West Show, three of 100 h. p. each. Flint & Pere Marquette Railroad Company, two of 75 h. p. each. Filer & Stowell Co., Milwaukee, one of 75 h. p.

Messrs. Siemens & Halske have also obtained a large contract for the installation of two 1000 h. p. dynamos in the World's Fair grounds. Besides the above mentioned contracts there have been a number of smaller machines of belted type sold, several being purchased by railroad depots, packing houses and breweries.

The factory in Chicago is now in operation and will shortly be in position to fill orders for all sorts of electrical apparatus on short time delivery. The company will make a specialty of the long distance transmission of power by multiphase currents, this system having been worked out by them in Europe to the smallest details.

The following District Agents have been appointed:—

Chas. D. Shain, General Eastern Agent, 136 Liberty street, New York City, with States of New York, Vermont, New Hampshire, Maine, Massachusetts, Connecticut, Rhode Island, New Jersey, Delaware, Pennsylvania, Maryland, West Virginia and Virginia.

Messrs. Markle & Harnish, Central States Agents, Perin Building, Cincinnati, O., with States of Michigan, Indiana, Ohio, Tennessee, Kentucky, N. and S. Carolina, Florida, Georgia, Alabama.

Wisconsin Electrical Construction Company, Milwaukee, with States of Wisconsin, Minnesota, North and South Dakota, and the Western Peninsula of Michigan.

Messrs. Littlefield & Meysenberg, Bank of Commerce Building, St. Louis, Mo., with States of Missouri, Kansas, Oklahoma, Indian Territory, Texas, Arkansas, Louisiana, Mississippi, and the strip of Kentucky and Tennessee due south of the boundary line between Illinois and Indiana.

The general offices are in the Monadnock Building, Chicago.

QUEEN & CO., INCORPORATED.

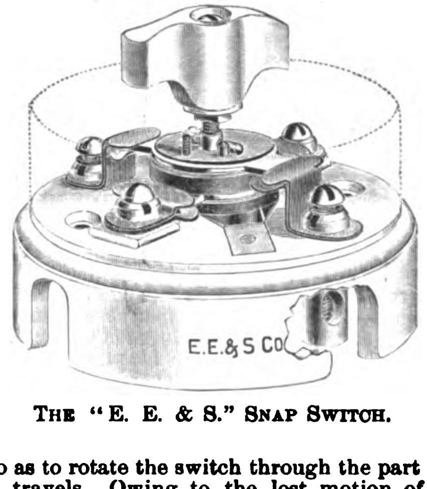
Queen & Co., incorporated, Philadelphia, are congratulating themselves upon the increasing demand for their "Magnetic Vane" ammeters and voltmeters as evidenced by the fact that more than twice as many of these instruments were sold by them in 1892 as in the preceding year. This advance is perhaps not astonishing when efficiency and cost of the apparatus are considered, but it shows a remarkable degree of appreciation on the part of purchasers.

The "M.-V." instruments are adapted for constant switchboard use, and voltmeters as well as ammeters can be left in circuit constantly, a feature of great importance to the central station manager. The makers are manufacturing in large quantities to supply demands which come from all over the United States. A number of prominent dynamo building companies have adopted the above type to install with isolated plants for incandescent lighting and for power circuits.

Descriptive circular No. 420 recently issued by Queen & Co. contains further information of value and will be mailed upon application.

THE "E. E. & S." SNAP SWITCH.

The accompanying illustration shows a 25 ampere, double pole, switch recently introduced and manufactured by the Electrical Engineering and Supply Company, of Syracuse, N. Y., and containing several novel and ingenious features. The contact is made by rotating metal arms mounted on a spindle and insulated from each other, so that they pass between two metal contact pieces mounted on each of the four binding posts and make a long wiping knife contact between the parts on both sides of the contact arms. In order to make and break instantly there are arranged in a recess in the porcelain base, two elliptical steel springs which press against the sides of a square frame-work holding a roller in each of its corners, so that in turning the handle the square frame-work is rotated until the rollers on two of the corners have compressed the two springs and are just passing the highest points when the contacts are about to be made or broken. Having passed this highest point, the springs press the rollers on the corners towards the centre so as to rotate the switch through the part of the circle in which it travels. Owing to the lost motion of the spindle there occurs instantly the make or break of the circuit with a sudden snap. The openings left in the side of the base facilitate surface wiring.



The "E. E. & S." Snap Switch.

This switch is said to have more carrying capacity than most switches designed for 25 amperes, and the wiping contacts constantly keeping the surface clean, the parts always run cool. The sudden break is of such length as to make the switch safe for use with currents of an electro-motive force of from 400 to 600 volts.

D'ODIARDI'S MEDICAL ELECTRICITY.

We have recently received from England a little pamphlet purporting to give a description of the electro-medical apparatus, etc., used by Professor D'Odiardi, of West Mall, Notting Hill Gate, and Cornwall Gardens, London, S. W. It is evident that in some branches of "medical" electricity, England is far ahead of America. We note that the pamphlet quotes Mr. Edison as saying that these instruments are "more effective and perfect than the apparatus hitherto employed;" and as admitting that he had only aided the distinguished professor "in a very modest way."

We cannot mention all the apparatus, but think that some of it will interest our readers, such, for example, as the lung healer in which "the vapor of extractum exoticum is loaded with static electricity at a high tension". Another amusing piece is the "electro-injector" which "can be employed with static or galvanic electricity. The current passes through a continuous liquid jet or is carried by separate drops according to the effects required. It cannot be replaced by any known instrument." But even this is a trifle compared with the "gaseous-high-electric tension current" (£50) which is "an apparatus for the simultaneous employment of magnetic lines of force, of static electricity and of voltaic and faradic currents on the bare body, immersed in various gases loaded with static electricity." But perhaps a patient might prefer the half-guinea diamagnetiser which is "employed with static electricity for softening of the brain" and other like diseases to which Professor D'Odiardi's clientèle seem peculiarly liable. The masterpiece of all is the "electro-spiral hood" (£500). This is as wonderful as it is costly. "The patient is kept alive in this apparatus until strength has been restored by nutrition. The wire of the coil is more than 300 miles long. The wind of the coil is 200,000." It appears that this will even make a dead man sit up and take his gruel, while an ordinary valetudinarian is soon rendered fit for a bout with Corbett.

And then there is the "deep plunge electrode" (2½ guineas) by means of which "the voltaic current is directed at will and may be made to plunge to any depth and in any direction without scattering or radiating." Or the "sleep-promoter," which "acts by itself," not only inviting to grateful slumber but regulating the bowels. This, like the "healing cup," (10 guineas, for private use only) is said to be a good substitute for chloroform, and rivals in benefit to mankind the 40 guinea "electro-inhaling cabinet," which is simply indispensable when the victim can afford to pay for it. Prof. D'Odiardi really ought to apply for space in the Electricity Building at the World's Fair.

AN ELECTRIC WHEEL OF CHICAGOAN DIMENSIONS.

The Detroit Bridge and Iron Works have secured the contract to build one of the biggest novelties to be seen at the World's Fair. Chicago and Pittsburgh capitalists will pay them $300,000 to construct what will be known as the Ferris wheel. It is to be constructed of iron and is 250 feet in diameter. It is to revolve on a shaft resting on two towers, each of which are to be over 125 feet high. On the circumference of the wheel is to be a series of cages arranged for the accommodation of passengers. When the wheel revolves the passenger is gradually raised from the ground to a height of 250 feet in the air. The wheel will be turned by electricity. There will be seating capacity for 2,150 persons.

The Utica Manufacturing and Supply Company are adding largely to their already long list of specialties. To quote from a circular recently issued by this company, their aim is not to furnish every-day cheap goods, but to manufacture and sell only the very best appliances, knowing from practical experience that every article used in the electrical business can not be made too good.

WESTERN NOTES.

The Central Electric Company have recently placed the Interior Conduit & Insulation Company's system of tubing and ducts in several of the largest buildings in Chicago, St. Louis and other western cities, the Newberry Library Building, the New Athletic Club, Congress Hall, and several other large buildings in Chicago being equipped throughout with this now essential system. The Lundell Motors, made up to 5 h. p., which have recently been put upon the market by the Interior Conduit & Insulation Company of New York, and are being introduced in the West by the Central Electric Company, are meeting with a ready sale, and the Central have already installed several of them in their territory. They have issued a complete descriptive circular and would be pleased to furnish them to any one desiring information bearing on the above.

Mr. P. W. Mitchell, of Doubleday, Mitchell & Co., 136 Liberty street, has been in Chicago booming the sale of their new quick break jaw switches. He reports business as very brisk.

The Electric Appliance Company will continue to represent the Emerson Electric Manufacturing Company of St. Louis as special Western selling agents for their celebrated Meston motor. The Electric Appliance Company handled this agency in a very satisfactory manner last summer, placing several hundred of the machines, the only difficulty being that the factory was unable to supply the heavy demand.

Preparations have been made this season however to anticipate any possible demand and a large number of machines have already been sold for May 1st delivery. It is rather cold business talking fan motors under the present atmospheric conditions, but the Electric Appliance Company have already booked a number of handsome orders and closed many of their sub-agency deals.

NEW ENGLAND NOTES

The Hawks Electric Company, has recently been organized under the laws of the State of Massachusetts, with a capital of $12,000, as successors to the business of H. C. Hawks, well and favorably known as a successful electrical engineer and contractor. The company have secured new and commodious quarters at 174 Summer street, Boston, and will carry on a general construction and supply business. Mr. Hawks, who has accepted the position of treasurer and manager of the company, has had a wide experience in the electrical business, having first started about eight years ago, with the Marr Construction Company of Pittsburgh, afterwards the North American Construction Company. Mr. Hawks has been in business for himself for the past two years, and has been exceptionally successful, and has now some fifteen important contracts in course of construction. Recently he has finished the construction of the North End Street Railway of Worcester, and has just closed a contract for 900 lights in one of the new factories of the Washburn and Moen Manufacturing Company, at Quinsigamund, near Worcester, Mass.

The Mather Electric Company, of Boston, have sent to a few of their friends a very beautiful calendar for 1893, which surpasses any before seen in the electrical business. It is a desk ornament, and contains a small calendar, a porcelain tablet for memoranda, and an actual clock "which goes" and keeps good time, the whole mounted on a handsome leather frame. All should send for one at once, as there is only a limited number.

Frank Ridlon and Company, of Boston, the well-known dealers in second-hand electrical apparatus, have at present for sale an extra large quantity of electric railway apparatus, sufficient to equip in every detail a road 100 miles in length. The apparatus includes generators, motors, wire and all overhead and necessary supplies. Street railway managers would do well to communicate with Mr. Ridlon before buying elsewhere.

Cumner, Craig and Company, of Boston, the young firm who have but recently gone into the electrical business, on their own account, have just been appointed exclusive New England agents for the Crocker-Wheeler Motor Company, of New York, and have already shown their business enterprise by sending in a number of orders for their well-known motors.

C. S. Knowles, of Boston, has recently opened branch stores at 143 Liberty street, New York, and at Room 109 Adams Express Building, Chicago, where he will keep large stocks of Tenax friction tape, splicing compound, Chatterton's compound, and other specialties which have achieved a wide reputation for unexcelled quality.

PHILADELPHIA NOTES.

Queen & Co., Incorporated, have sold nearly all the Ayrton & Perry ammeters and voltmeters, which they advertised so extensively at reduced prices, but a few still remain which are offered at a mere fraction of the original manufacturing cost; for instance, an ammeter with capacity of 400 amperes being placed at $16.00. Any one who wants a portable instrument for general testing, where great accuracy is not required, might find it very advantageous to purchase now, bef re the stock is entirely exhausted. Descriptive circular No. 355 will be mailed by the makers upon application.

Mr. Paul S. Reeves, of 760 South Broad street, Philadelphia, has enlarged the capacity of his plant last year to such an extent as to enable him to turn out 2,200,000 pounds of castings; an increase of 800,000 pounds over the output during 1891. He is making a specialty of castings for electrical work.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XV. FEBRUARY 1, 1893. No. 248.

WILLIAM WALLACE, AND HIS CONTRIBUTIONS TO THE ELECTRICAL INDUSTRIES.[1]—I.

BY

Wm. J. Hammer

I.

THE history of the development of the electric lighting industry in this country from its incipiency to this day, when it represents the gigantic capitalization of between four and five hundred millions of dollars, will, it is safe to say, never be recorded in a manner to do more than scant justice to the industry itself or to those who have the right to be termed its pioneers. Few, it is safe to say, of those connected with this important art to-day, can appreciate what that word "pioneer" really means, and none does so more fully than the author of this sketch. Any history of electric lighting, written or to be written, would indeed be incomplete without a reference to the early work in this industry of William Wallace, of Ansonia, Conn., and in view of the importance of his work in this and other branches of electrical science, and in view of the fact that text books and other scientific literature of to-day make little or no reference to what he has accomplished, it seems exceedingly appropriate that some recognition be made of his work, for Mr. Wallace represents the highest type of our American manufacturer, who, while occupied with the progress and development of important manufacturing industries, has still time, energy and capital to employ in scientific research and experimentation, in the development of a new art, and adding to the sum of human knowledge. To the writer, who has enjoyed an intimate and valued friendship with Mr. Wallace, extending over the past eleven years, it is a pleasure and privilege to present a record of some of his work which he has collected from various reliable sources, together with a short biographical sketch, which he feels sure will prove of interest to the readers of The Electrical Engineer.

William Wallace.

William Wallace whose portrait is presented herewith, was born in the City of Manchester, England, March 16th, 1825, and came to America with his parents, Thomas and Agnes Wallace, in 1832. Several years passed before the family settled upon a permanent location, but in 1841 they went to Birmingham, Conn., and the father and his three sons entered the employ of the Howe Pin Co. A few years later the father commenced the manufacture of brass and brass wire on his own account, forming in 1848, the firm of Wallace & Sons, consisting of himself and three boys.

Two years later they removed to the adjoining town of Ansonia, Conn., in order to take advantage of the water power supplied by the canal of Anson G. Phelps, which had recently been constructed. A single foot of water was estimated as giving sufficient power for their purposes, and it is interesting to observe from the appended cut of the works of Wallace & Sons, as they exist to-day, to what enormous proportions the concern has grown. It covers many acres of ground. Within a few months several new and extensive buildings have been added and the power required absorbs not only that of two engines of 1,000 h. p. each, but taxes the capacity of a dozen smaller engines scattered about the works. The concern employs over a thousand hands.

In 1853 the company was changed from a partnership to a corporation, retaining the firm name of Wallace & Sons, by which it is known to-day. Little or no electrical work is done to-day by the Company save in the manufacture of wire for electric lighting and power purposes, a specialty being feeder and trolley wire. The product of the factories embraces copper and brass goods in infinite variety, sheet brass and copper, brass, copper and German silver wire, copper rivets and brass metal chains, pins, cartridge cases, kerosene burners, lamps, and a great deal of other detail metal work.

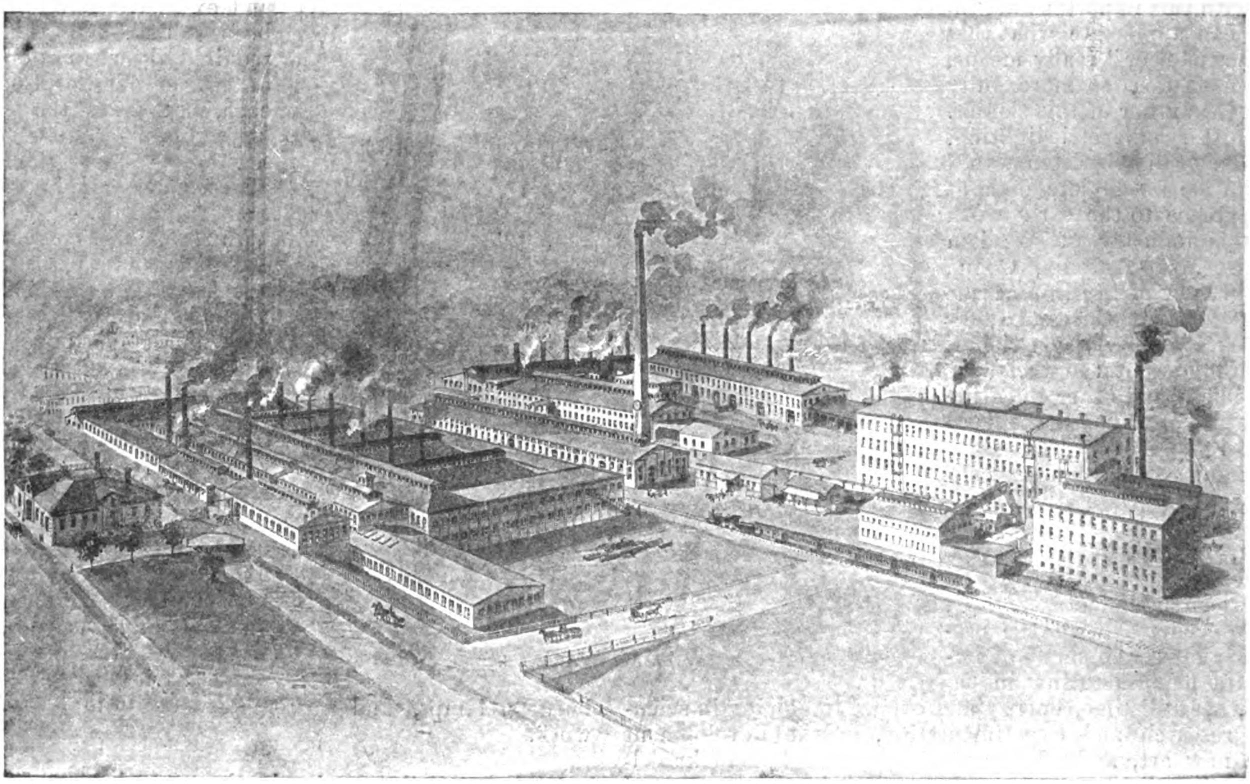
II.

William Wallace, who is the second son of Thomas Wallace, deceased, is still living, hale and hearty, at the age of 67, and takes a very active interest in the Company, of which he is the President. He is a man of powerful physique, standing nearly six feet in height, and possessed of a boundless amount of energy and enthusiasm in his work, and a perfect genius for mechanical pursuits. Many of the special tools and machines in the factory have been devised by him, and he never seems so happy as when busy among his workmen at the mills, giving, as he has always done, his personal supervision to the mechanical affairs of this immense concern, mapping out the work, laying out new buildings, installing new engines, boilers and tools, and ever placing himself upon a plane with his men, who one and all hold him in the highest respect and affection.

---

[1] Copyrighted 1893, by W. J. Hammer.

Mr. Edison's Goblet.



Bird's-Eye View of Wallace & Sons' Brass and Copper Rolling and Wire Mills at Ansonia, Conn.

The writer has frequently visited the Ansonia Works and watched with absorbing interest the powerful rolling machines and intricate pin and other machinery at work. One department he was informed had been visited by but four persons including himself, save by certain of the employees, since it was started. It contains apparatus which the company believed could be better protected by secrecy than by patents. A particular wire-drawing machine contained over $30,000 worth of diamonds and he was shown a store of onyx used in the lamp department representing a value of $25,000. It is stated that the company manufactures the largest amount of copper wire of any concern in the United States. The factory possesses the largest and tallest chimney stack in the state, rising to the height of 202½ feet from the ground, 16 feet square at the base and 7½ feet at the top. Sixty feet from the ground is the huge factory clock.

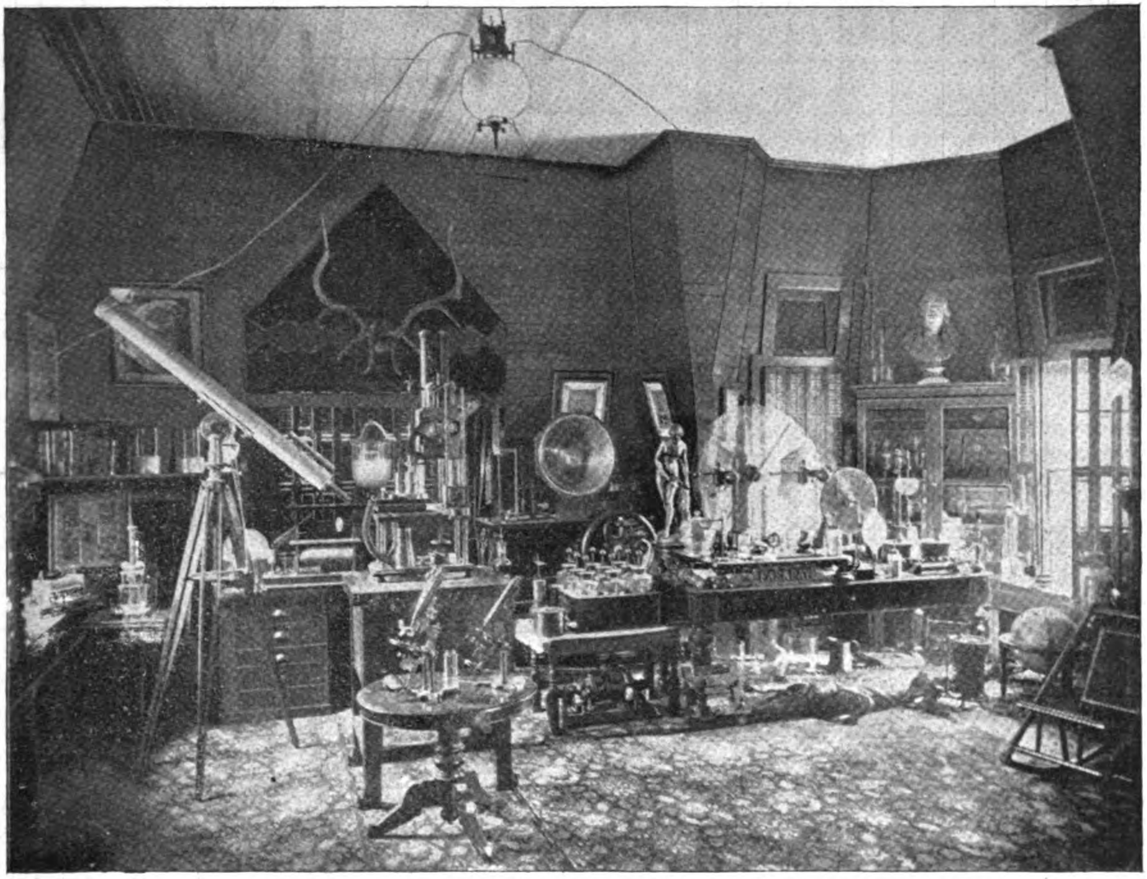
Adjoining the works of Wallace & Sons, stands the beautiful office building of the company, which is one of the handsomest equipped factory offices in the state, while a stone's throw from the office is situated the private residence of Mr. Wallace, which in the early days of electric lighting in this country was the "Mecca" towards which were directed the steps of many of the most prominent scientific men of the day as well as the steps of many of those who subsequently became prominently identified with the electric lighting industry. Among these may be mentioned Thomas A. Edison, who visited Mr. Wallace in the in the fall of 1878, in company with Dr. Henry Draper, Professor C. F. Chandler, Professor George F. Barker and Mr. Charles F. Batchelor, Mr. Edison's chief assistant. Here Mr. Edison witnessed Mr. Wallace's experiments in electric lighting, and secured from him a Wallace-Farmer dynamo, and a set of Wallace lamps for lighting his laboratory in Menlo Park, N. J. There is shown on this page a goblet which Mr. Wallace still has in his possession and which he treasures very highly, upon which Mr. Edison has inscribed in tiny lettery by means of a diamond the inscription "Thomas A. Edison, September 8, 1878, made under the electric light." The others in the party made similar inscriptions upon goblets, but with the exception of Mr. Edison's and one of Prof. Barker's they have all been, by some accident, destroyed. Before leaving Ansonia, Mr. Edison turned to Mr. Wallace and remarked, "Wallace, I believe I can beat you making electric light, I do not think you are working in the right direction." He then returned to Menlo Park, and shortly thereafter was caused the great excitement by his demonstrating to the public the subdivision of the electric light by the employment of the Edison incandescent lamp, filing his first patent for an incandescent lamp October 14, 1878.

Mr. Wallace has always endorsed Mr. Edison's claims as the inventor of the incandescent electric lamp, and so frequently has the writer thus heard him express himself, and so warmly has he praised the wonderful genius of Edison that the writer thought it would be interesting to learn the estimate Mr. Edison would give of Mr. Wallace and his work, and he sought an opportunity to question him. Mr. Edison spoke most kindly of Mr. Wallace, and among other things said: "Wallace is one of the earliest pioneers in electrical matters in this country. He has done a great deal of good work for which others have received the credit, and the work which he did in the early days of electric lighting others have benefitted largely by and he has been crowded to one side and forgotten."

Mr. Wallace's home, which has for many years been presided over by his daughter Eloise, contains may objects of great interest and value, and notwithstanding the busy life which he has led, he has frequently spent a portion of the year in travel about this country and Europe, and has gathered many of the treasures with which his home is filled. He has enjoyed a very wide acquaintance among the eminent scientific men both here and abroad, and they are always welcome guests at his home, where they are sure not only to meet with a hearty reception but find much to interest an entertain them.

III.

In the illustration herewith is shown a portion of Mr. Wallace's private laboratory, which is situated in the upper portion of his house. In this scientific den Mr. Wallace has spent many of his happiest hours, surrounded with his books and apparatus, and with gas, electricity, hot and cold water, and everything else at his command which is essential in a well equipped laboratory. A large screen is stretched across the entire end of one room, upon which Mr. Wallace projects by means of an electrical lantern which he has equipped, views, of which he possesses over three thousand, of various places of interest in different parts of the world which he has visited, and illustrations of various astronomical, microscopical, electrical and other scientific subjects; and frequently friends and neighbors gather in the laboratory in the evening to be edified by these displays and experiments which Mr. Wallace shows them in electricity and other matters.



WILLIAM WALLACE'S PRIVATE LABORATORY.

Mr. Wallace has kept aloof from all political entanglements in his town, and has steadily pursued his business and occupations; yet he has decided political opinions, is an ardent Republican and has ever been a friend of the veteran soldier.

In 1880 Mr. Wallace was taken seriously ill with pneumonia, and during the latter part of that year and early in 1881 he was forced to neglect his electrical and other work entirely. When he had sufficiently recovered to go on with his work he found his competitors in the electric lighting field had to a considerable extent forestalled him, and the duties of his position at the mills commanded so much of his time and attention that he was compelled to drop his aggressive work in the field which he had made so peculiarly his own; and it is not too much to say that had not his health broken down at this critical period, the name of Wallace would to-day stand at the forefront of those identified with the electric lighting industry.

During Mr. Wallace's serious illness in March, 1881, he was visited at his home by two of his intimate friends, men eminent in science, Prof. Henry Draper and Prof. George F. Barker. They had shipped to Ansonia in advance of them a mysterious box, the contents of which were unpacked and set up in Mr. Wallace's bedroom and proved to be a beautiful set of Prof. Crookes' vacuum tubes and apparatus for experiments on radiant matter, a gift from Prof. Draper to Mr. Wallace. The apparatus was exhibited to Mr. Wallace as he lay on his sick-bed and he says to-day that he believes this kindly act of theirs and the pleasure and benefit which he derived from the wonderful experiments which he witnessed, saved his life.

The writer recently asked Mr. Wallace what one thing in his past life of wonderful activity had left its greatest impress upon his mind, and after a moment's thought, he said, "The satisfaction that I felt in seeing work perfectly for the first time a mechanism which I had devised and over which I had been working for a very long period and which simplified very much certain processes in the mills."

THEORETICAL ELEMENTS OF ELECTRO-DYNAMIC MACHINERY.—XIV.

BY

A. E. Kennelly

STRESS DISTRIBUTIONS (CONTINUED).

THE stress distributions in magnetic circuits containing iron may next be examined, commencing with the simplest case. Let us take a closed circular solenoid of which the section S is so small relatively to the generating radii, that the intensity within it is practically uniform. This intensity will be $B = \frac{2Nc}{r}$. The total stress exerted along the flux paths will be $\frac{B^2}{8\pi} = \frac{N^2c^2}{2\pi r^2}$ and the total amount of this over the section S will be $\frac{SN^2c^2}{2\pi r^2}$. Suppose $r =$ 15 cms. $S = 2$ sq. cms., $N = 500$ turns, and $c = 0.5 = 5.0$

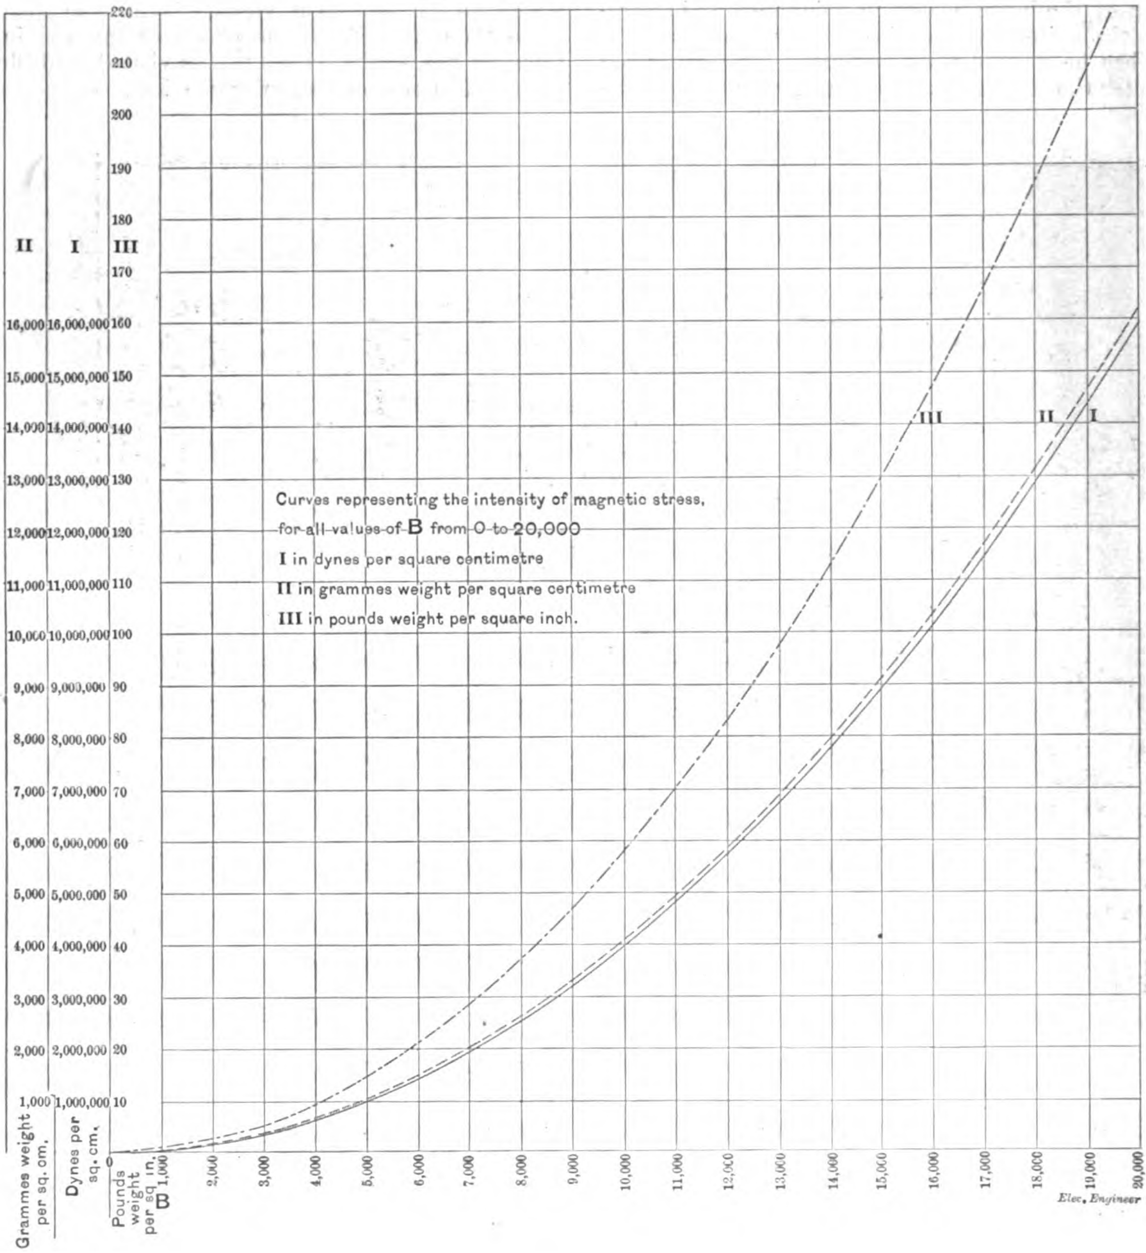


FIG. 34.

amperes; we have $B = \frac{2 \times 500 \times 0.5}{15} = 33.3$ C. G. S. lines per sq. cm. so that the total tension will be $\frac{2 \times 500^2 \times 0.5^2}{2 \times 3.14 \times 15^2}$ $= 88.4$ dynes, and this will be the stress exerted along the walls of the solenoid, across any radial section.

If now a soft iron core be inserted so as to fill the solenoid, the prime intensity of 33.3 will excite a total resultant intensity in the iron of $33.3\,\mu$ or perhaps 16,650 C. G. S. lines per sq. cm., since μ would be about 500 for this excitation. The stress for this intensity would be $\frac{(16,650)^2}{8\pi}$ or approximately 11,000,000 dynes per sq. cm., and the total stress, 22,000,000 dynes, will be supported by the iron core and the solenoid together. Since we may regard the core as magnetically equivalent to an independent internal solenoid of definite excitation, we know by the results reached in the preceding chapter, that the stress on the walls of the outer solenoid will be, so far as mechanical freedom will permit, equal to that sustained before the insertion of the inner solenoid, in this case the iron core. The coil in this case will therefore retain the stress of 88.4 dynes, and the remainder, or 21,999,911.6 dynes, will be supported by the iron core, assuming that coil and core are mechanically independent or frictionless. It is evident that in nearly all cases that can practically occur, the share of stress supported by the solenoid is relatively so small when it encloses iron, that the core may be regarded as exerting the entire stress.

If the ring were divided into halves by a plane through the axis of revolution, each section would support 22 megadynes, and the total attraction between the two halves would be 44 megadynes, or 44.85 kilogrammes weight. The introduction of the iron core has increased the power 250,000 times.

Fig. 34, gives the curves representing the value of $\frac{B^2}{8\pi}$ in dynes per sq. cm., grammes weight per sq. cm., and pounds weight per sq. inch, enabling the tension corresponding to any flux density to be determined by inspection. Thus, if two smooth plane surfaces of iron are brought into contact, and a uniform intensity of 14,000 passes perpendicularly across the plane of junction, the attraction between those surfaces will be 7.8 megadynes, or 8 kilogrammes per sq. cm., or 113 lbs. per sq. inch of contact surface. If the plates are not in contact, but lie parallel to and facing each other, their attraction will still be the same if the intensity remains unaltered in value or distribution. In practice, of course, this is not generally the case, and the intervention of an air-space between the plates will cause the flux to diminish and to deviate from the perpendicular in its passage.

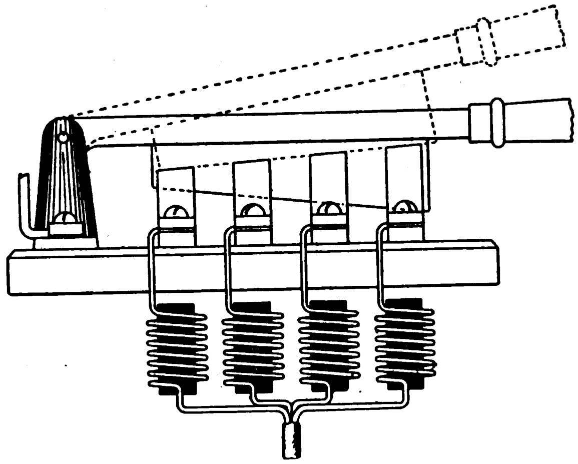
Suppose that the air gap between two parallel and similar opposed pole faces is d cms. across, the intensity at, and near, the polar edges, will be curved and variable from point to point, but at any point in the air gap between the poles not less than $\frac{d}{2}$ cms. from the polar edge the intensity B_d say, will be practically uniform, and perpendicular across, so that the stress, or attraction between the poles will be $\frac{B_d^2}{8\pi}$ dynes per sq. cm. of surface, and less than this near the edges.

The next case in order of complexity, is that of a closed circular solenoid in which, owing to the area of cross-section, the intensity may not be regarded as uniform. The prime intensity varies from $\frac{2Nc}{r}$ at the inner wall to $\frac{2Nc}{R}$ at the outer. With an iron core, the value of μ will generally differ at these limits, and the resultant intensities will tend to approach more closely than their excitations. The value of B will differ at different points in a section, not only on account of difference in the radius, but also owing to the variation in μ due to the different excitations thus established. We can no longer obtain the total stress from the product of $\frac{B^2}{8\pi}$ and the cross sectional area, but some process of average or summation must be resorted to, according to the degree of accuracy desired.

As a numerical instance, suppose $R=15$, and $r=10$, to be the outer and inner generating radii of the soft iron core whose breadth is $h=5$, and section square, $N=600$, and $c=3$ amperes, $=0.3$. Then the prime intensity at the inner wall is $\frac{2 \times 500 \times 0.3}{10} = 36$, and at the outer wall $\frac{2 \times 600 \times 0.3}{15}$ $= 24$. For $H = 36$, μ might be 400 in soft iron, and for $H = 24$, 500, so that the resultant intensity would range from $24 \times 500 = 12,000$ at the outside to $36 \times 400 = 14,400$ at the inside of the core, the corresponding stresses being 5.85 and 8.4 kilogrammes per sq. cm. respectively. As a first approximation to the total stress, we might take the mean value of these extreme limits or 7.125, and the area of cross section, 25 sq. cms., making a product of 178.1 kilogrammes weight. A closer result would be obtained by determining a series of prime intensities for intermediate radii, multiplying each by its corresponding μ, and then taking the average of the $\frac{B^2}{8\pi}$ values. Or an empirical relation could be assigned by trial between μ and B so that the total stress could be determined by integral calculus. The limit of accuracy would be ultimately determined by the precision with which the scale of μ could be experimentally determined.

THE THOMSON MULTIPLE CONTACT SWITCH.

The difficulty of constructing a multiple contact switch for heavy currents in such a manner that the break shall be absolutely simultaneous at all points is well-known. It is also evident that if the breaks are successive, though the intervals be exceedingly small, the current energy will be concentrated upon the last point of contact and tend to injure the switch.



THOMSON MULTIPLE CONTACT SWITCH.

To obviate this danger Professor Elihu Thomson places in circuit with each of the multiple contacts an induction coil so arranged that under ordinary circumstances no impedence is offered to the current flow, but which allow only the proper proportion of current to traverse each contact upon the opening of the switch. The increased current, tending to rush through the contact last broken, sets up a counter electromotive force that prevents its passage during the short interval between the last break and those preceding.

The accompanying illustration shows the device so clearly as to render further explanation superfluous.

LAMINATED OR DIVIDED IRON AND OTHER METALLIC MASSES IN ELECTROMAGNETIC APPARATUS.—V.

BY

Thos D Lockwood

Faraday.

Long after they were brought out in 1868 and 1873 the first and second editions of Ferguson's "Electricity" ranked high as textbooks. On page 187 of the latter edition, the advantages of iron wire cores are discussed with great intelligence, and enlarged upon; the wires must be insulated, which, however, is sufficiently effected by rust that gathers on them. If tubes are employed, they must be slit longitudinally.

In 1873 also, we arrive at the first distinct word concerning the dividing into discs of drum armature cores, appearing since Henry's note on Ettingshausen's proposal. It is to be found in a note by M. A. Pellerin, transcribed from *Comptes Rendus*, Vol. 77, p. 561, by *The Telegraphic Journal*, London, to the effect that to prevent heating arising in the Siemens bobbin from induction currents flowing in the mass of the metal core, and other causes, the core is to be built up of soft iron insulated discs.

In his *Exposè des Applications De L'Electricitè*, the Count Du Moncel, exercising his functions of chronicler, tells us (Vol. 1, p. 243) that "through Page's researches, we know that Sturgeon it was, who substituted bundles of iron wires or plates, discs of iron rolled spirally, or simply sheets of laminated plates as cores for induction coils."

The British patent of Edward H. C. Monckton, No. 3509, of Oct. 12, 1874, describes a variety of laminated and split electromagnetic cores, and also slit enclosing cylinders for electromagnets. To make a magnet core several rods or flat, thin sheets are combined instead of a single bar, and these may be electroplated, or thin sheets of copper or brass may be interposed between each two.

In the British patent, of Desmond Fitzgerald, No. 3807, of Nov. 2, 1875, is described an induction coil having a central soft iron core, and a surrounding cylinder of soft iron, both core and cylinder being longitudinally grooved or slit.

In 1876, we find a considerable amount of activity in the subject. In February of that year, Prof. John Trowbridge communicated a Memoir to the American Academy of Arts and Sciences, "On the effect of thin plates of iron used as armatures to electromagnets." This paper referred to a previous one presented April 13, 1875. Among other points mentioned which had been experimentally determined, was the following: That to produce longer sparks from an induction coil whose core was formed with a closed magnetic circuit, it was necessary to substitute for the "armatures" thin iron plates. This being done, a gain of about 400 per cent. was noticed. A still further slight gain was manifested when the armature plates were placed edgewise on the cores. Prof. Trowbridge's Memoir appears in the *Philosophical Magazine* (Vol. 1, N. S., 1876, p. 564), and in the *Journal of the Telegraph*, New York (Vol. 9, No. 13, July 1, 1876, p. 198). It is also noticed in the *Scientific American* (Vol. 34, N. S., No. 23, June 3, 1876, p. 356), and in the *Telegraphic Journal*, London (June 15, 1876, Vol. 4, p. 177).

In this year, also, Dr. Eduard Zetzsche published in *Dingler's Polytechnisches Journal* an account of the new Siemens machine, which was copied in the *Journal of the Telegraph*, New York (Vol. 9, No. 16, Aug. 15, 1876, p. 243), which states that when the armature core of the Siemens machine is constructed to revolve with the coils, it should, to avoid *Foucault currents*, be made of "coils of iron wire wound on a wooden cylinder." From this point forward, the division of iron in electromagnetic apparatus becomes so popular, and its mention in patents and publications so frequent, that its further classification by years is now undesirable, and the references to follow are therefore arranged in the several classes of United States and other patents, and then of publications.

THE NEW WESTINGHOUSE STOPPER LAMP.

In our last issue mention was made of the invitation extended by the Westinghouse Company to its friends to inspect the machinery to be exhibited by it at the World's Fair, and also to inspect the new stopper lamps, a large number of which are burning at the shops in Alleghany.

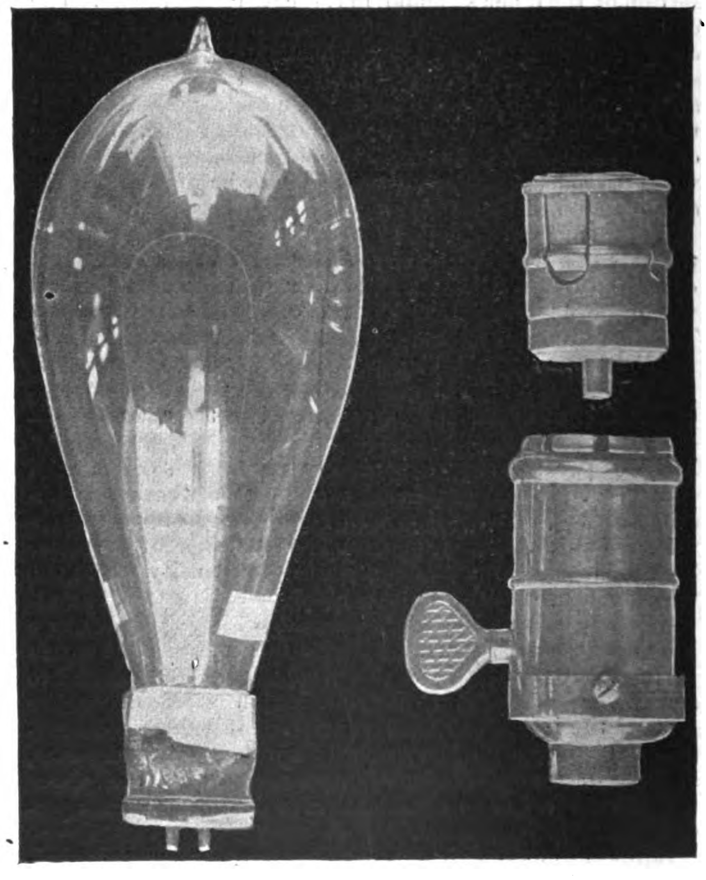


Fig. 1.—Westinghouse Stopper Lamp, Base and Socket.

(Photographed from Lamp.)

We have fully described the machinery and have also had occasion to refer to and describe the new lamp in our issue of Oct. 26, 1892, but we think our readers will be interested in some exact photographic reproductions which we give on this page and which, for the first time, show accurately all the details of the new lamp. Our engraving, Fig. 1, shows the lamp complete, separated from the removable Westinghouse base and socket; Fig. 2 shows the stopper removed from the lamp. It will be noted that the stopper, consisting of glass, has the leading-in wires passed through it for a distance of an inch and a quarter.

This length allows of a perfect seal being obtained. The leading-in wires are of iron, and a special glass is employed, the coefficient of expansion of which is practically the same as that of the iron; thus the use of platinum is avoided. The iron leading-in wires, it will be observed, are thickened at the bottom, making two stubs which are quite stiff, upon which the contacts in the base bear.

The stopper is ground in a special machine and fits into the corresponding neck in the bulb of the lamp. When the stopper is inserted, a cement is applied which aids to maintain a perfect seal. When it becomes necessary to renew the filament, the stopper is removed, a new filament is attached to the leading-in wires, the stopper is re-inserted, and the lamp is again exhausted. This operation can be accomplished at a very small cost, and hence there ought to be no excuse for the continued use of blackened lamps.

During the exhausting of the lamps, the Westinghouse Company introduce nitrogen gas at intervals, for the displacement of the oxygen of the air, so that the residual atmosphere, when exhaustion has been carried to the last point, consists largely, if not entirely, of nitrogen.

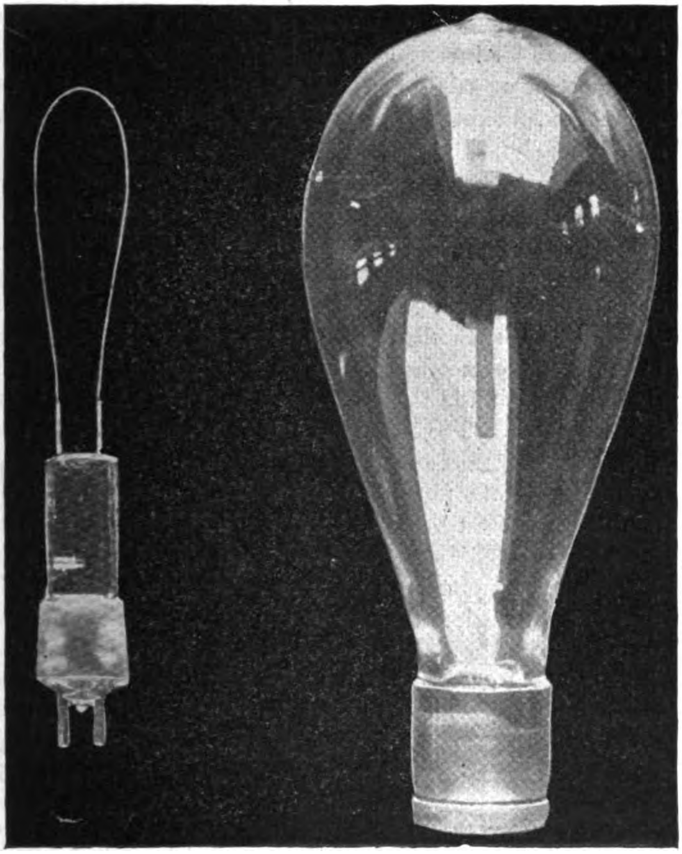

FIG. 2.—STOPPER AND BULB OF NEW WESTINGHOUSE LAMP.

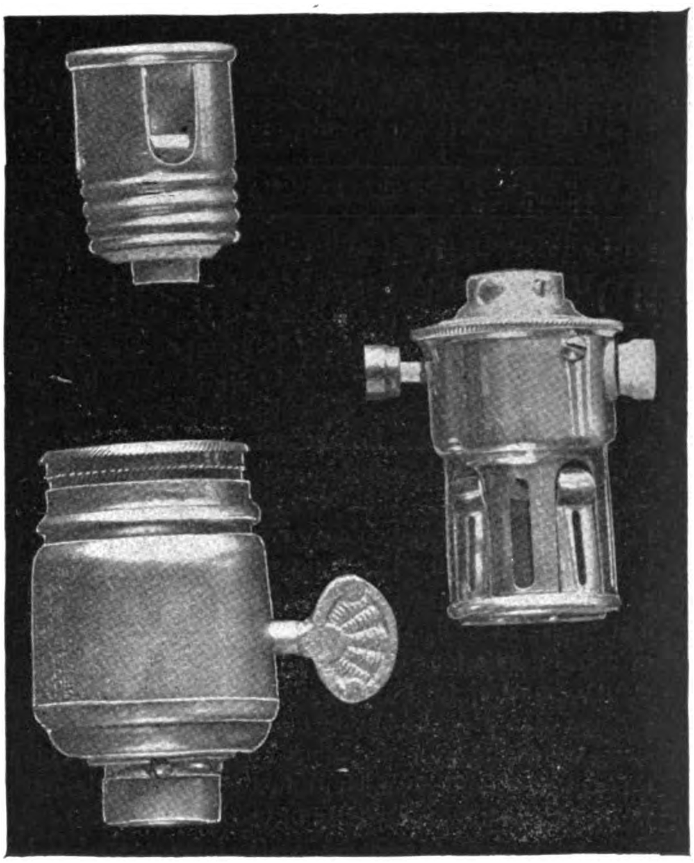

FIGS. 3 AND 4.—SOCKETS FOR WESTINGHOUSE STOPPER LAMP.

(Photographed from Lamp and Sockets.)

As will be seen in Fig. 2, the lamp is complete in itself and can be readily adapted to any type of socket; thus Fig. 1, illustrates the Westinghouse base and socket. The lamp is pushed into the base by which the contacts are made with the leading-in wires; the base is then pushed into the socket, no screw motion being employed. Fig. 3 shows the base employed for use on Edison sockets.

A special and very simple form of pendant switch has also been designed for use with the lamp, as illustrated in Fig. 4. By merely pushing in the white or black button, the lamp is switched on or off, and this can be readily accomplished by the use of but one hand.

"EVER WELCOME".

A WELL known New York medical man writes us "Please find enclosed check for $3 for renewed subscription to your ever welcome ELECTRICAL ENGINEER. Its weekly arrival diminishes my maximum of long felt wants most materially."

THE ELECTRIC vs. THE STEAM LOCOMOTIVE.

BY H. S. A. C.

WHILE sauntering about in the city of Lynn, Mass., not long ago, I saw a unique tug of war contest that I thought might be interesting to the readers of the ENGINEER.

The engineer of a large freight engine doing duty on the B. & M. R. R. had his steam horse coupled to a queer shaped piece of mechanism, which had the general outlines of the old gun boat "Monitor." Later I learned that it was a new electric locomotive that had been built at the Thomson-Houston factory, and that the engineers were giving it a practical test.

When the word "go" was given, on went the steam and "juice" with a jump. The steam engineer up to this time thought that he had an easy opponent, the electric locomotive being so much smaller and apparently lighter, but when he found himself being pulled along by the other he was a little disheartened and looked troubled.

A happy idea brightened up his countenance, and thrusting open the sand box to its fullest capacity, he gave the little electric locomotive more than it could do. But only for a short time, for when the electric locomotive reached the sandy track it started up with new life and pulled the steam locomotive back to the starting point, but no farther; for just as soon as it reached the clean track the steam locomotive would have its sway.

And so it went on, back and forth, until the steam engineer, getting disgusted at being outdone by such a small insignificant rival, without any puffing or blowing or shovelling of coal, left his engine, and started for home muttering about the dangers of electricity and the deadly trolley wire.

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

VOL. XV. NEW YORK, FEBRUARY 1, 1893. No. 248.

GOEBEL.

DURING the past week almost the sole topic of discussion in electrical circles has been the unexpected and surprising character of the defence put in by the attorneys of the Beacon Company to the application for an injunction made in behalf of the General Electric Company under the Edison incandescent lamp patent; in respect to which proceedings were still pending when our last issue went to press. There is as yet but little to add to the very full details of the case which we were able to lay before the readers of THE ELECTRICAL ENGINEER, not only in advance of our contemporaries of the weekly, but of the daily press as well. After listening patiently, and with evident interest for three days, to the affidavits and arguments of counsel, the Court granted a week for printing the papers in the case and for the handing up of briefs and citations of authorities by counsel on both sides. Pending this respite the Beacon lamp factory is doubtless being worked to its utmost capacity of production.

There naturally exists a wide difference of opinion among those most interested, not merely as to the intrinsic merit of the defence presented, as summed up in our columns last week so fully, but as to the effect which its presentation at this late day will be likely to have upon the future fortunes of the Edison patent. As the learned counsel for the complainant took care to remind the Court, there is scarcely a single instance on record of a patent covering an invention of great importance and monetary value, in which a determined effort has not been made to show that some other person had made the invention at a date anterior to that of the patentee; and, as he further remarked, it is also true that few if any of these attempts have resulted in the overthrow of the patent. Not to go outside of our own electrical field, the claim of Jackson to the invention of the telegraph, and that of Drawbaugh to the invention of the telephone, will be recalled as conspicuous examples. In view of such facts as these, the Court must be expected to view the allegations now made in behalf of the prior invention and use of the incandescent lamp by Goebel with unusual suspicion; indeed it would be manifestly wrong for it to do otherwise.

Unless the evidence proves to be so convincing as to leave no room for a reasonable doubt, we do not see how the Court can do otherwise than grant the injunction asked for. At the same time the fact must not be lost sight of, that former cases can furnish no complete precedent for this one. Every such case must be judged on its own merits, and, in the present one, the real inquiry must be as to the truth of the statements sworn to by the witnesses, of the force and pertinence of which every reader may judge for himself, from the abstracts printed in our last issue.

The statute provides that a patent may be granted to an applicant for an invention or discovery only upon the following conditions, among others, viz.: that it must have been "not known or used by others in this country, * * * before his invention or discovery thereof, and not in public use or on sale for more than two years prior to his application, unless the same is proved to have been abandoned."

An inventor, having once made and perfected an invention, may, if he please, use it in private, or he may use it in public, or sell or otherwise permit its use by the public, and never attempt to patent it. Either procedure may constitute what is legally termed an "abandonment" of the invention, such abandonment inuring, in the first case, to the benefit of a subsequent independent inventor, should there be one, and in the second case to the benefit of the general public. The last named state of facts constitutes a "public use," and it is such a use that is alleged to have taken place in the present instance. Hence, there are two points which must be established beyond all possible doubt, in order to overthrow the Edison patent; first that Goebel's lamp was a complete and operative structure, and, second, that it was used in public or by the public more than two years before the invention of Edison. Evidently, the former is to be the main point of controversy, for there can be no question that if Goebel's lamps were operative, and were used in the way that many witnesses affirm them to have been, namely, to attract spectators to look through a telescope for a small fee—described so graphically in our pages last week—it was just as effectually a "public use" as are the hundreds of arc lights which nightly blaze along the Bowery for the avowed purpose of inveigling the passers-by to drop their nickels into the tills of its thrifty shopkeepers. If in the present instance, the evidence and the exhibits are sufficient to convince the Court that Goebel's lamps were operative lamps, and that they were made by him at the time the witnesses say they were made, then it can apparently pursue no other course than to refuse the injunction, and compel the complainant to re-try the original issue on the new evidence now brought forward. In that event it would be, to say the least, extremely doubtful if any result could possibly be reached before the final expiration of the patent. Thus, from the present outlook it seems probable, that within a very short time the ultimate fate of the incandescent lamp patent must virtually be decided.

ELECTRIC RAILWAY DEPARTMENT.

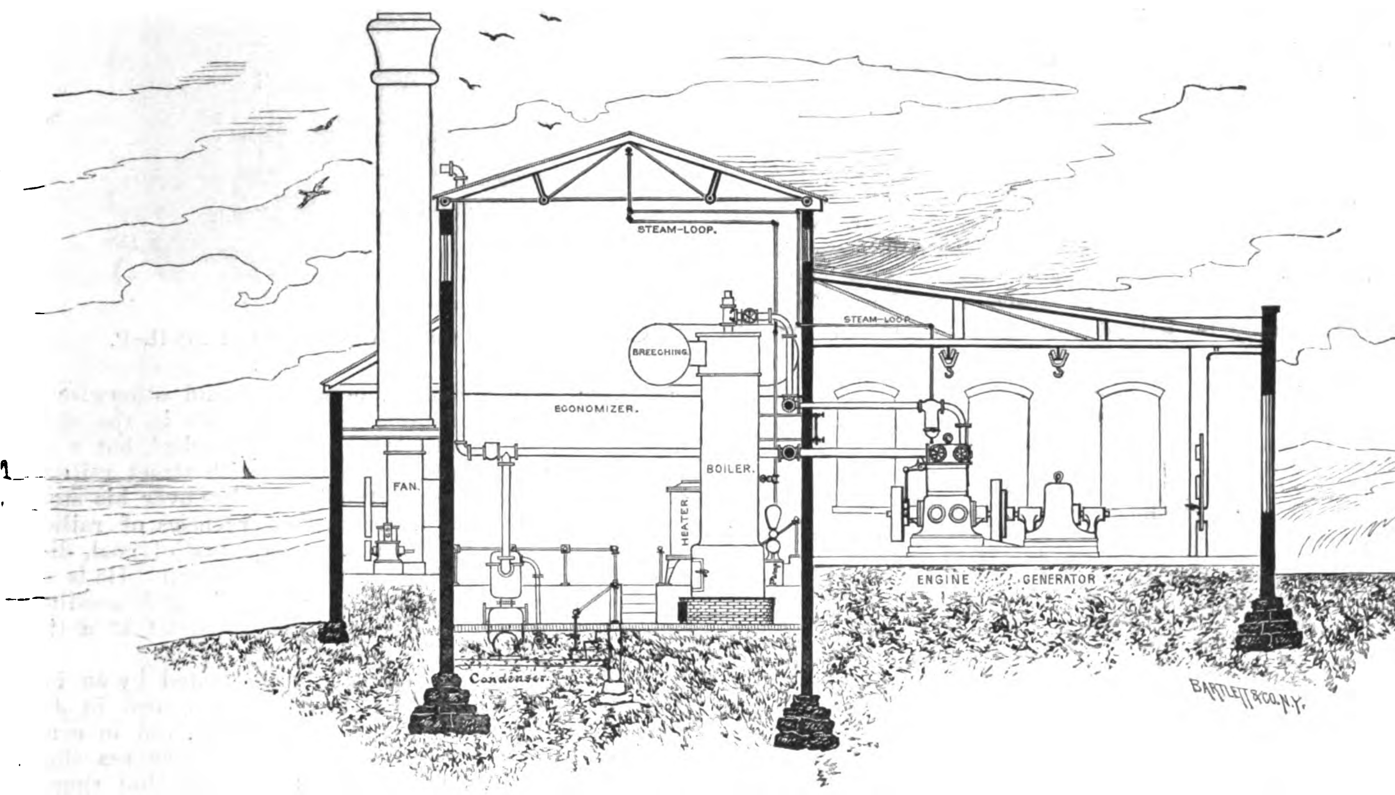
THE POWER STATION OF THE NEW HAVEN AND WEST HAVEN STREET RAILWAY, NEW HAVEN, CONN.

BY

A. C. Shaw.

I.

The New Haven and West Haven Street Railway operate a line of double track road between "The Green" in the city of New Haven, Conn., and a seaside resort known as Savin Rock, in West Haven, with two branches in the residence district, being a total distance of 9¼ miles, of which 4½ miles are double tracked. Their present equipment consists of 42 cars, comprising seven open cars having two motors of 30 h. p. each, and 16 cars equipped with one 30 h. p. motor, nine cars with single 20 h. p. motors, and ten trailers. The road has the usual city and suburban trade throughout the year, and in the summer season it handles a heavy pleasure travel to the Savin Rock resort.



SECTIONAL ELEVATION OF THE NEW HAVEN AND WEST HAVEN STREET RAILROAD POWER STATION, NEW HAVEN, CONN.

The power station which this article illustrates is a remarkable example of modern engineering in this department. So far as known, it is the first power station in this country which has followed the European practice in completely equiping with direct-connected, slow speed dynamos, or "Kodaks"; and the whole design of the plant in its minor details is so thorough a departure from the older lines of practice, as to attract the attention of engineers and railway men throughout the country. The power station was constructed under contract by Messrs. Westinghouse, Church, Kerr & Co.; the work being designed and supervised by Mr. William Lee Church, of the above concern. It is worthy of remark that the contract was awarded on the 6th of April, 1892, and ground was broken on the following day. The contractors, although not formally bound, were under a moral obligation to operate the road electrically on the 4th of July; the company having largely disposed of its equipment of horses, relying on the power plant to handle the holiday crowd. As the event resulted, steam was raised on the 1st day of July, and the road was ready so far as the power was concerned, to take care of the 4th of July traffic, and as a matter of fact did so, to the extent of the full car equipment at that time in service.

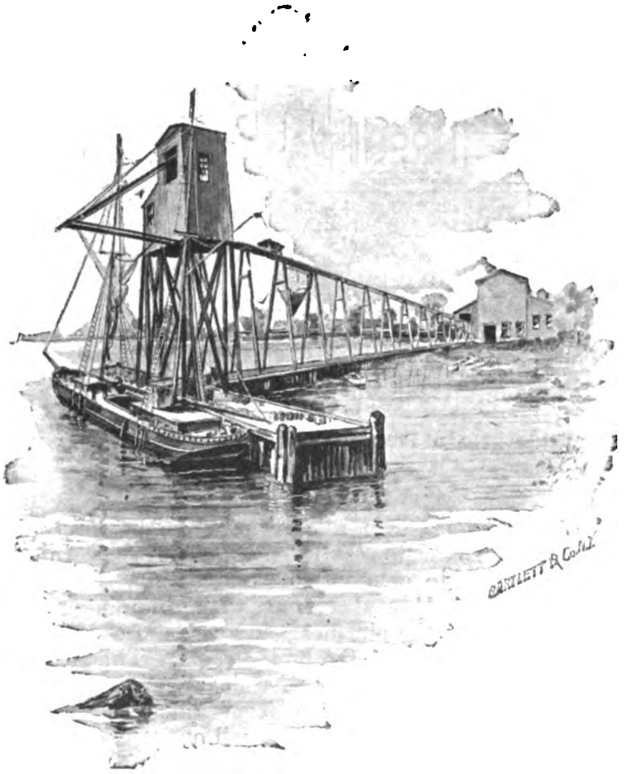
II.

The plant is located on a lot situated at the west end of the West Haven bridge at tide water. A pier runs out 300 feet to the ship channel so that coal may be handled by the cargo. A Hunt tramway with dumping car carries the coal from the pier head and distributes it through a coal pocket outside of the boiler room. This pocket is carried on heavy timbers, with a floor incline at such an angle as to let the coal run freely into the fire-room through openings in the building wall opposite each boiler. A coal supply for ten weeks can be thus stored, or sufficient to tide over any possible freezing of the bay during a severe winter.

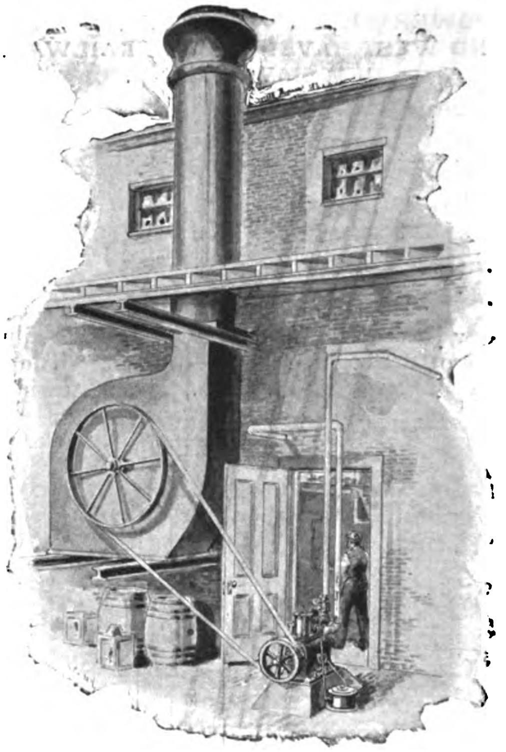
The building is laid out for a total plant of 1,000 h. p. nominal generator capacity; 500 h. p. being installed at present under the original contract. The boiler-room is 72x29 feet with a clear height of 26 feet under the trusses. The floor is of brick laid in cement, being on a level with the grade outside. A slope of about 4 feet in the lot enables the floor of the dynamo room to be raised above the boiler-room, and at the same time to be entered at grade from the front of the building. The boiler plant at present consists of three Manning boilers of 150 h. p. each ; two of which are adequate to run the present plant to its full capacity, the third standing as relay. These boilers are furnished with shaking grates, and an ash car runs on a track within convenient distance of the ash pits.

III.

A most striking feature of this plant is the perfect control of the fires independent of outside conditions, by the use of mechanical suction draft. The observer will be struck by the absence of the usual chimney stack, and will find it difficult to believe that an insignificant steel stack 4 feet in diameter and showing 9 feet above the ridge of the roof, is the only provision for firing the ultimate plant of 750 h. p. of boilers to their fullest capacity. The smoke flues from the boilers are carefully protected by non-conducting material so as to save all the available heat for transference to the feed water in the economizer. The smoke flue after running to the back of the boiler-room turns down into a brick chamber, in which is a Lowcock economizer, the scrapers of which are operated by a little engine on its upper deck. A bypass with damper runs underneath the floor of the economizer, so that the latter can be cut out for repairs without interfering with the boiler service. The cold end of the economizer opens directly into a large slow-running exhaust fan whose wheel is 6 feet, and its case 9 feet, in diameter. This fan stands on I beams in an annex to the boiler-room, and discharges directly up into the bottom of the stack before mentioned. In the base of the stack a steam nozzle may be placed as a relay in case of temporary repairs to the fan, the chances of which may be judged from the fact that it runs in ordinary service at from 40 to 50 turns, and in rare emergencies at 80 turns. At the latter speed the air can be heard to whistle through the ash pit doors, and an intensity of combustion is obtained which practically doubles the rated horse-power of the boilers. The power for the fan is a Westinghouse engine of nominally 5 h. p., but which runs under a throttle barely started from its seat. The actual horse-power has never yet been indicated, but it is nominal. The economizer extracts all available heat from the gases, reducing their temperature in the fan to practically that of the incoming feed water, and returning to the boiler a heat value which would otherwise be required for the production of natural draft in the chimney. The economical results are very marked, but a not less important feature in connection with street railways is the entire control which the fireman has over his steam pressure under all the fluctuating emergencies of railway service. He no longer fears a poor quality of coal, dirty tubes, or dirty fires after a long and hard run. He is not appalled by a heavy snow fall, or by a sluggish condition of the atmosphere which is apt to kill the draft at a time when the tracks are the greasiest.

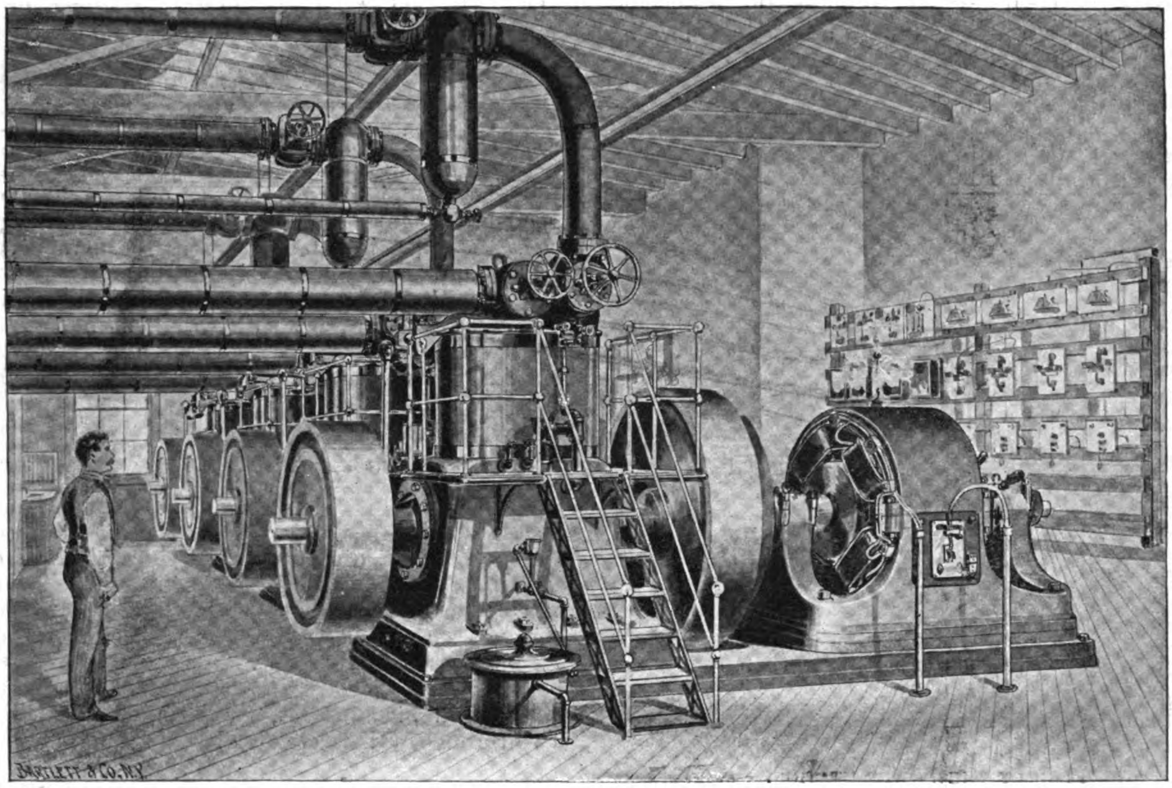


Coal Hoist and Tram.



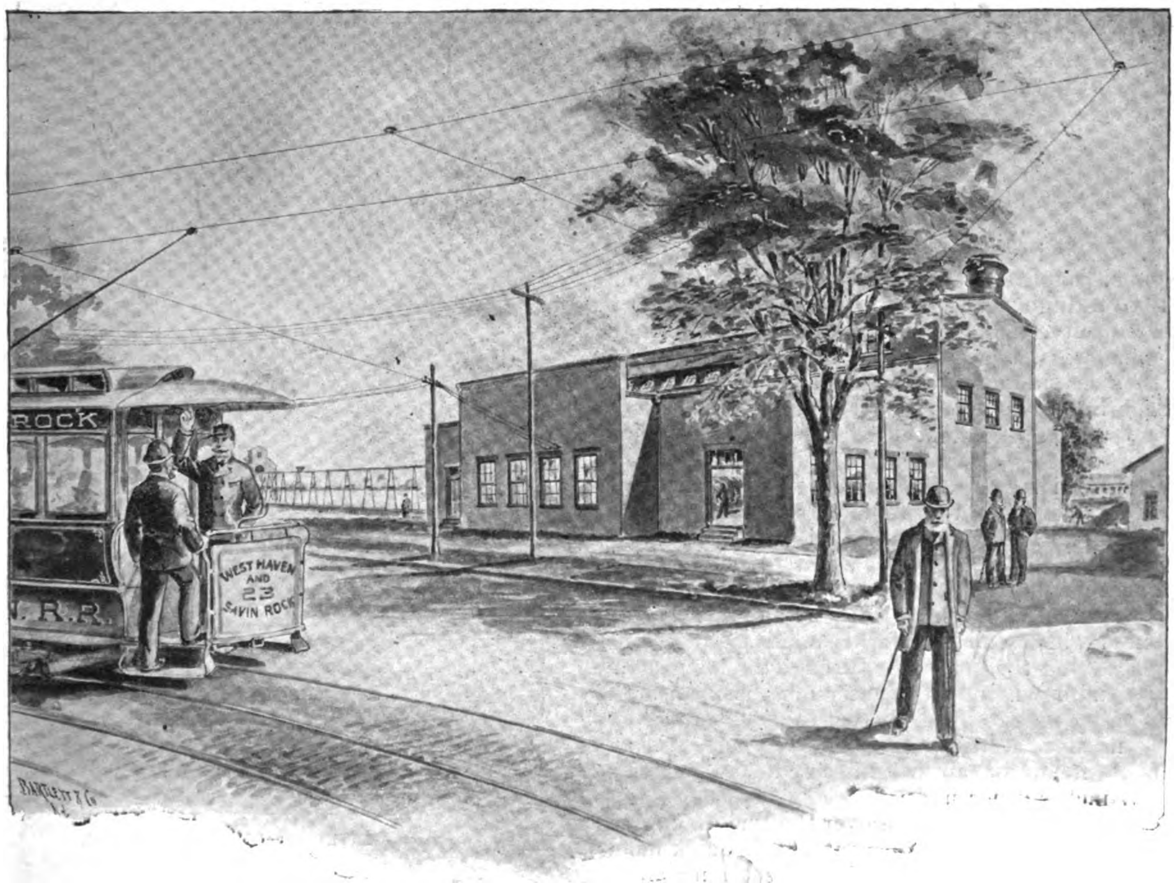
Mechanical Draft and Stack for 750 H. P.

Its capabilities were brilliantly illustrated by an incident occurring shortly after the road was opened in July last. The day was a sultry summer day, and in consequence a large crowd had accumulated at the sea shore. The company had only four motor cars at that time in service ; the remainder of the traffic being taken care of by the horse cars. Several other motor cars were equipped and standing in the car shed, but no motormen had been assigned them. A railway man need not be told that a green motorman will use an extravagant amount of current, and will unlatch the circuit breakers with a frequency which is ruinous to the morals of the man at the other end. In the evening a heavy thunder storm came up and the crowd immediately flocked for the cars. Word was telephoned to the power-house that the crowd was coming and must be taken care of ; that the new cars would be run out with green men and must be handled at all hazards. One boiler and one engine were running ; the second boiler standing banked from the night before, and showing a pressure of 45 lbs. The fan was speeded up a few turns, the second engine immediately started from the same boiler, and the fire hauled down in the second boiler. In eight minutes from receiving the message, the second boiler showed 120 lbs. of steam, and the first boiler had pulled through the double duty and the car service performed was without a break. These facts appeal mightily to the railway manager, who cannot make up for lost time in dealing with the public, but must go for what is in sight each and every moment.



BARTLETT & CO. N.Y.

GENERATOR ROOM.

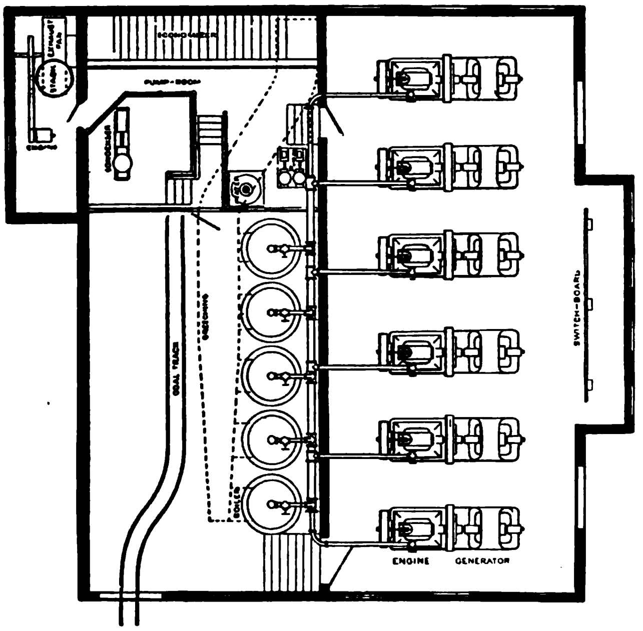


ROCK
WEST HAVEN AND 23 SAVIN ROCK
N.R.R.
BARTLETT & Co

1,000 H. P. POWER STATION, NEW HAVEN AND WEST HAVEN STREET RAILWAY.

IV.

In the boiler-room is the usual double equipment of feed pumps, either pump being adequate to supply the full battery of boilers. These pumps take water through a meter, so that by weighing the coal, and dividing into the water, a running log of the evaporative duty can be taken and reported to the office. The feed water is first carried through a National heater, into which are turned the exhausts from the feed pumps, condenser, fan engine, etc., the whole being sufficient to raise the temperature to about 150°. From the heater it goes through the economizer, and reappears with a temperature of about 330°, in which condition it is fed to the boilers.



Plan of the Power Station.

A pit in the boiler-room contains a Deane independent condenser which receives the exhaust from all the main engines in the generator room. The injection is salt water drawn through a suction pipe from the end of the pier, and discharged to waste; its value being as a producer of vacuum only.

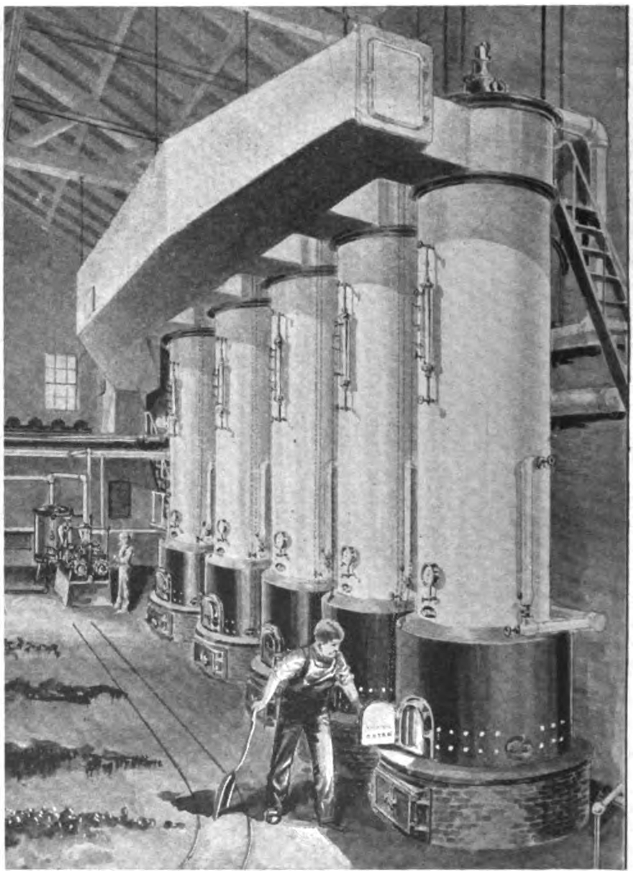
V.

Entering the generator-room, we find a floor space 72 x 31 feet and 16 feet high under the trusses. This room contains at present three Westinghouse compound engines of 160 h. p. each, with a maximum capacity of 200 h. p. on 125 lbs. steam, coupled direct through a flexible insulating coupling to Westinghouse slow-speed generators of 160 h. p. nominal capacity. The room will ultimately contain six of these generators, aggregating a round 1000 h. p. of rating, with a maximum capacity much in excess of this figure. Each Kodak occupies a floor space 6 feet x 16 feet 4 inches, and the arrangement is as shown in the interior view, the distance between centres being 11 feet. A separator is placed in the steam line to each engine near the throttle and an independent steam loop runs from each one, getting its rise in the roof of the boiler-house. Absolutely dry steam is thus insured, all water of condensation or entrainment is returned to the boilers, and the engines are ready to start each morning without annoyance from water. The 12 inch exhaust line is made tight against vacuum by screwing the pipe clear through the flanges and rivetting the end down into a countersink. Expansion is taken care of by copper bends in both the steam and exhaust lines, and since starting the plant not a sign of leakage either of steam or air has appeared, and a steady vacuum of 27 inches is maintained.

A trolley fall runs on an I beam over the line of engines and over the line of generators, permitting of quick handling in case of repairs. An alcove 30 feet long and 6 feet deep contains a skeleton switchboard of quartered oak so located as to be accessible from all sides without projecting into the main body of the room. The floor is laid in diagonal stuff of hard pine, and ample provision is made for artistic lighting on the generators and switchboard, the lighting circuits being on a shunt from the main circuits. The perfection of the engines as to speed is strikingly exhibited by the perfect steadiness of the lights, notwithstanding the rapid and extreme fluctuations of load common to railway service.

VI.

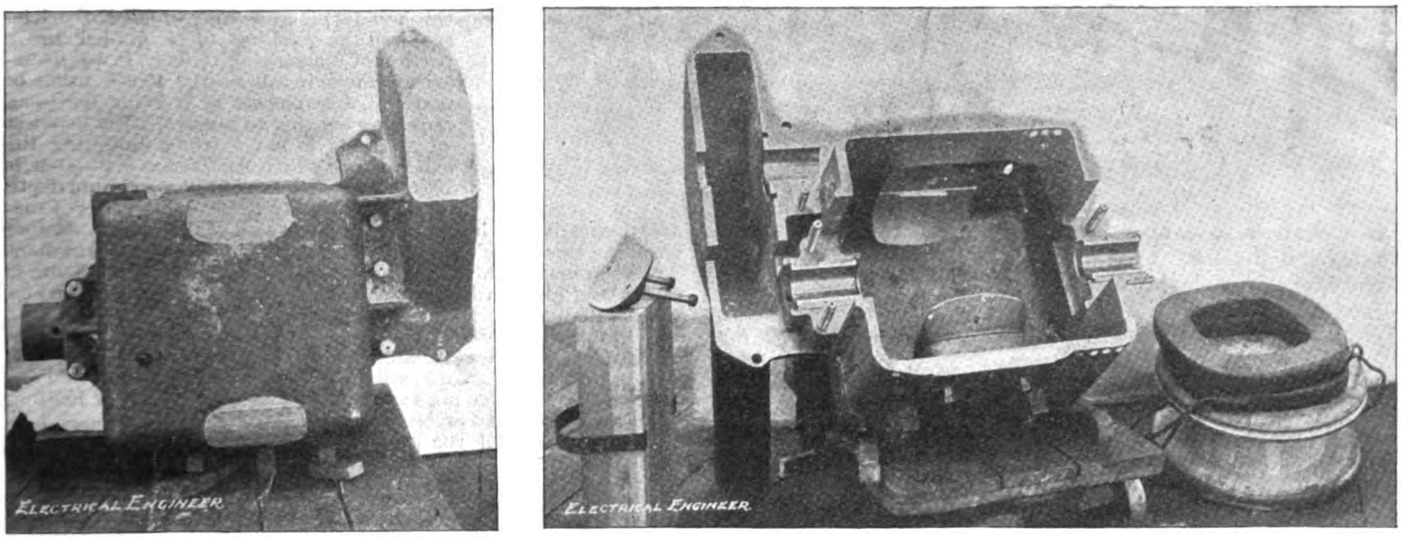
A fact which will strike every practical man, is the remarkably small space occupied by the entire plant. We show here a building 74 x 63 feet outside which contains a 1000 h. p. plant complete, including engines, generators, switchboard, boiler plant with relay, economizer, condenser, feed pumps, and all sundries, including a most generous space for the fire room. On the plan which is still adhered to in many stations of a slow-speed engine driving through counter-shafting, the entire ground area of this whole building would just suffice to contain with fair room for accessibility, a 1000 h. p. horizontal triple-expansion engine *alone*, without any provision whatever for boiler room, counter-shafting, or generators. In other words, the total space under the Kodak design for accommodating the *whole plant* is less than 5 sq. feet per electrical horse-power, or not over one-third of that required for the same equipment on the basis of counter-shafting in a plant of equal size. This for a small plant. A more recent design for a complete power station of 8,000 h. p. generator capacity on a still more compact arrangement reduced to 2.3 sq. feet per electrical h. p. The bearing of this fact upon the cost of real estate, particularly in city plants, and upon the cost of the building, is apparent, amounting to a reduction of fully two-thirds of this heavy item.



Interior of Boiler Room.

The effect upon the capital account is obvious and the next point of interest is the result in the operating expenses. In this particular, the records of the above described station we are told, have probably not been approached by any other station, small or large, thus far constructed.

No official test has yet been made, as the complete car equipment was not in service until the summer rush was over. A detailed test will be made in the summer of '93, but the company has kept running records of the car mileage and coal consumption, which give the essential information. Owing to the non-completion of the pier and the suction line to the condenser, the engines were run non-condensing for some months after the plant was started. During this time an average of almost exactly 2,000 car-miles per day was performed at a cost of coal of exactly $18 ; coal being $3.67 per ton delivered in the bins. This reduces to $\frac{9}{10}$ of one cent per car-mile. About the first of October the condenser was connected, with an immediate reduction to .82 of a cent per car-mile. At the present writing the plant is running on almost exactly four tons of coal per day, gross consumption, including not only banking of fires, steam for pumps, condenser, fan engines, etc., but also the electric *heating* of all the cars in one of the severest winters on record, or slightly less than three-quarters of a cent per car-mile for power, light and heat. This at the comparatively high price of coal prevailing in New England, is a result which demands the thoughtful attention and comparison of railway managers, and very conclusively settles the question of the adaptability of a proper design of compound engine either condensing or non-condensing, to the variable loads of railway service. It further indicates the economical advantage of converting the power in the most direct manner possible from the piston of the engine to the armature of the dynamo, without the frictional losses due to counter-shafting, clutches, etc.



Figs. 1 and 2.—The Curtis Electric Railway Motor; Top and Bottom Views of Case.

VII.

The operating force of the station consists of a chief engineer, who is held responsible for the plant in general, and who is on duty from starting time until 4 p. m., at which time the second engineer goes on and does duty until midnight. There are three firemen running eight hour turns, changing at 6 a. m., 2 p. m. and 10 p. m., the last man acting also as night watchman, and raising steam and starting one engine for the morning run.

The station above described is a bold departure in engineering, but one which rests upon a substantial foundation of practical experience and a full appreciation of the commercial as well as the engineering side of the problem involved. Its success has been marked; and the officers of the company are unstinted in their commendation of the whole plant, and of the contracting firm.

THE CURTIS ELECTRIC RAILWAY MOTOR.

The experience already gained in electric railroading has been sufficient to demonstrate that simplicity in construction and operation of the apparatus, above all else, must be the prominent feature, if lasting success is to be achieved. This becomes apparent when we consider that, unlike apparatus which is housed and well taken care of, as for instance central station apparatus, the electric car equipment must of necessity be placed in charge of men, with little, if any, experience in the handling of machinery.

The functions of the motor-man are simply to operate certain levers to accomplish certain effects, and it is too much to expect of him that he should possess that judgment and discrimination displayed by trained engineers and machinists, who understand the construction and operation of apparatus under their charge; and even if he possessed such a knowledge, the peculiar position in which he is placed and the constant strain upon his mind to avoid accidents to passengers, and to passers by and vehicles on the line of the road, would make the exercise of such judgment frequently impossible. It is of the utmost importance, therefore, that the man should be entirely free from such cares from the time the car leaves the car house until it returns.

With this condition of affairs in view, the Curtis Electric Manufacturing Company of Pacific avenue, Jersey City, N. J., have brought out a new railway motor equipment which is designed to fulfil all the conditions which may be imposed upon this class of apparatus in actual practice.

The accompanying illustration, Fig. 3, gives a view of the motor with the lid raised so as to expose the armature. Fig. 2 shows the body of the motor with all the windings and armature removed. It will be noted that the armature is encased in a single casting in the form of a box with a light cover, thus making a completely water and dirt proof machine. This box of cast steel, ¾ inch thick, has cast on its sides the pole pieces, of which there are two, the motor being a two pole machine. Fig. 1 shows the bottom of the motor case.

One of the prime necessities in a railway motor equipment is the facility for getting at all parts of the motor with the least amount of trouble. To accomplish this the arrangement of the Curtis motor is such that everything can be gotten at and removed through the car floor without running the car over a pit. Thus, for instance, the armature can be raised vertically clear of all obstruction, and this is effected by making the top of the curved pole pieces removable.

One of the most vulnerable spots in an electric motor is the gear case. This is usually cast separately and attached to the motor body by bolts. In the Curtis equipment, however, the gear case is of steel cast integral with the body of the motor and of the same thickness. This not only gives it extraordinary strength and makes it practically indestructible, but, in addition, makes it impossible for the gear case to work loose, as frequently occurs where the gear cases are bolted to the body of the motor.

The motor box illustrated in Fig. 3 is 24 inches square and 21 inches deep including cover. Within the box is placed the armature of the Pacinnoti type. The armature is wound with copper tape which not only greatly facilitates and shortens the time of winding, but also allows of considerable economy in space; at the same time it makes rewinding a very simple process. By this means three sections of the armature can be and are wound with one continuous length of wire.

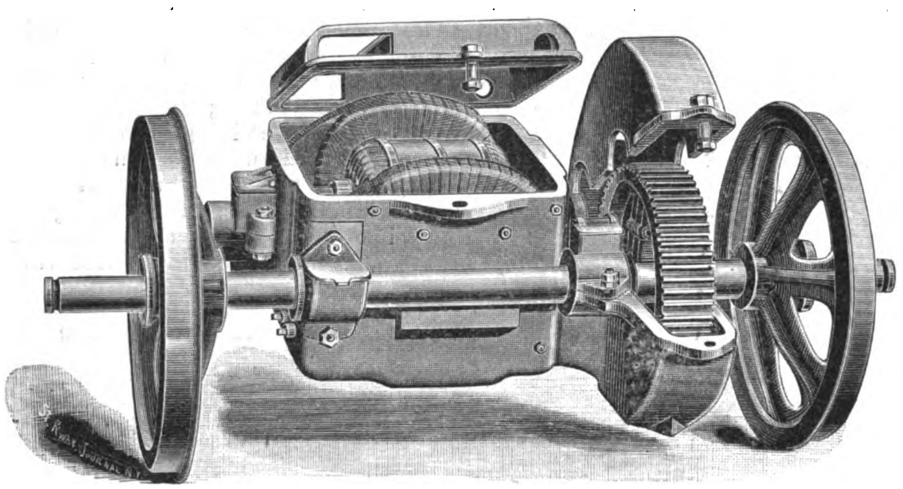


Fig. 3.—The New Curtis Street Railway Motor.

The connections to the commutator are made by means of flexible wire joined to each outlet; the joints are wound with fine copper tape, shellaced and insulated by tape, no solder being used so that repairs can be easily effected. The wire on the armature is wound in mica troughs so that the insulation is perfect.

Owing to the excellent design of the machine only 190 pounds of copper are required for both field and armature, which together have a combined resistance of about one ohm. One reason for the small amount of wire required will be apparent when it is noted that the design of the field is such that the field coils are brought very close to the armature, thus preventing the scattering of the magnetic lines.

The motor is of the single reduction type, the gearing being in the ratio of four to one, and is designed to have a car speed of 15 miles an hour for the average service. The mechanical design has also been thoroughly worked out and the machine is the result of a thoroughly exhaustive study of all the requirements which the practice of the last five years has shown to be essential to successful operation.

EXTENDING ELECTRIC ROADS IN BROOKLYN.

The Brooklyn, Bath and West End Railroad, which was originally known as the Gunther Railroad, and was the pioneer route to Coney Island, has been purchased by E. E. Deniston, the representative of the syndicate of capitalists, which has been investing heavily recently in Brooklyn surface railroads. The road has not made any money for some years, owing to the sharp competition and the amount paid for the property, it is said, was only between $500,000 and $600,000. The route, however, is regarded as one of the finest to the Island, and should the road pass under the control of the new Traction Company, which recently purchased the Atlantic avenue road, and the electric trolley be substituted for steam on the West End road, there would be a complete trolley system established between the South Ferry in Brooklyn and Coney Island. It is understood that this scheme is involved in the purchase of the road.

BY ELECTRIC CAR TO WASHINGTON'S HOME.

Until recently the only means of reaching the home and tomb of Washington at Mt. Vernon, 14 miles below the City of Washington, on the opposite side of the Potomac, was by steamer leaving the city every morning and returning every afternoon. On the 21st of September, however, the Washington, Alexandria and Mt. Vernon Electric Railway opened to the public that portion of their line between Alexandria and Mt. Vernon, affording, in connection with the Baltimore and Potomac Railroad, or the Washington and Alexandria Ferry, a very interesting and much quicker means of reaching Mt. Vernon.

The line, starting at the railroad station, or the ferry landing, passes a number of interesting points of the old historic town to the outskirts of the city on the South, whence it crosses, on an imposing trestle bridge which spans the expanding mouth of Hunting Creek, to the newly-laid-out town of New Alexandria. From this point the line bears southwest through an open and nearly level section for two miles, when it begins to rise and enter a rolling country, passing for several miles through fields, across streams and over wooded heights until the trestle over Little Hunting Creek is reached. Beyond this and just before reaching Mt. Vernon a five per cent. grade some 1,500 feet in length is reached. This ascent made and the terminus of the road, the Mansion of Washington is in sight.

The whole line comprises about 10½ miles of track, most of which, passing through farm lands and wooded districts, required the road-bed to be graded and a portion of it cleared of timber. It was necessary to move in all nearly 40,000 yards of material, a large part of it being hard-pan requiring blasting to remove. The heaviest of the cuts is made while mounting the heights upon which Mt. Vernon is situated, is 700 feet in length, and has a maximum depth of 22 feet. Nearly 10,000 cubic yards of material, mostly clay hard-pan were excavated at this point. Before reaching this cut a deep ravine is crossed requiring an embankment 18 feet in maximum height and about 1,000 feet in length. Some 30 culverts of glazed tile pipe with brick head walls are required on the whole line.

The trestle bridge which spans Hunting Creek and connects Alexandria with New Alexandria is over a half mile in length, 30 feet in width, and affords a fine drive-way to the newly-laid-out town. It is built on piles and has a plate-girder draw of 100-foot span, furnished and erected by R. W. Hildrith & Co.

That portion of the line within the city limits, comprising some 2½ miles of single track and turnouts, is laid with 55-pound and 70-pound Wharton girder rail, supported on chairs resting on ties spaced 2½ feet apart. The remainder of the line from the city line on the south to Mt. Vernon is a single track with turnouts, and is laid with 50-pound Standard T-rail spiked directly to ties. The ties are 6 inches square and spaced 2½ feet apart, and the track is lined, surfaced and ballasted in accordance with present steam railroad practice.

Electric Railway Cut Near Mt. Vernon.

Two supplementary wires of galvanized iron, No. 0, B. & S. are laid, one at each rail, under the ties. The rails are single-bonded at each joint, every bond being connected to one of the supplementary wires. Ground plates made of galvanized iron are sunk every 500 feet and connected to the two ground wires.

In the overhead line construction in the city, octagonal pine poles are used, the trolley wire, No. 0 copper wire, being suspended by spans. Outside the city, round cedar poles are employed, the trolley wire being suspended by bracket arms. The General Electric Company's line material is used throughout. From the station two No. 3/0 feeders run into the city and four No. 3/0 feeders extend southward towards Mt. Vernon, two of them extending a portion of the way only.

The power house, located near the southern end of the long bridge, a short distance from the line, but close to the water's edge, is a brick building, 68 x 92 feet, and contains a car house in addition to the power plant. The latter consists of two 150 h. p. horizontal tubular boilers, furnished and erected by W. P. Fleming & Co., and two Greene engines of 200 h. p. each. The current is furnished by two Edison generators, of 200 h. p. each, belted direct to the engines.

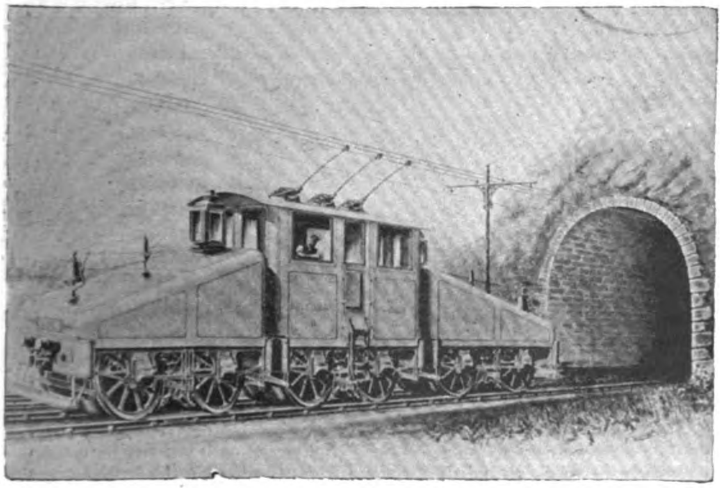
The cars were furnished by the J. G. Brill Company. For city use there are two 16 feet cars equipped with two 15 h. p. W. P. motors furnished by the General Electric Company. For use on the Mt. Vernon portion of the line there are four 34 feet cars, each equipped with two 30 h. p. motors of similar design. The whole work has been planned with the intention of making fast time between Alexandria and Mt. Vernon; and a speed of 25 to 30 miles per hour is readily attained. The construction of the road was undertaken by the Mt. Vernon Construction Company in the month of June, Mr. Chas. H. Davis acting as chief engineer.

On July 5th the contracts for track construction, grading and line construction were awarded to the Woodbridge & Turner Engineering Company. The work of construction was begun on the 16th of July, and in the face of almost insuperable difficulties the work was so far completed that a trip was made to Mt. Vernon on the 20th of September, and the line opened to the public the following day. Considering the magnitude of this work, the especially difficult features that were required to be overcome, and the shortness of the time in which the whole was accomplished, it is believed that it will compare favorably with any electric railway construction of similar character and magnitude that has yet been accomplished. The work was done under the supervision Mr. B. P. Flint for the chief engineer; Mr. A. S. Kibbe having charge of the track construction and grading, and Mr. Herbert Turner, of the line construction, for the contractors; and a large part of the credit for the thorough and rapid completion of this extensive work is due to their energy and skill.

We show herewith one of the grades on the road, the view being taken recently, while heavy snow has been on the ground. In The Electrical Engineer of Dec. 21, 1892, a few details of the road were given with a view of the long trestle bridge in course of construction.

ELECTRIC LOCOMOTIVE FOR THE B. & O.

For some time past the General Electric Company has been engaged in the design and construction of a heavy freight and passenger locomotive, to be operated by electricity, and to be used in the new tunnel under the City of Baltimore. It is required of this electric locomotive that it shall handle regular passenger trains and also assist steam locomotives in the haulage of heavy freight. In view of the great interest taken in the subject, we are glad to republish from the *Forum* magazine for February, the first illustration of the locomotive to appear. It will be seen that while adhering more or less to conventional lines of construction, various departures from orthodox practice have been made, chiefly, it may be pointed out, in dividing up the power and in applying it to the axles by a number of motors each driving directly by an armature on its own axle. The trolley arrangement is of familiar type, the chief novelty lying again in the principle of subdivison, adapted to secure continuity of contact with such a heavy current as will be required for the work.

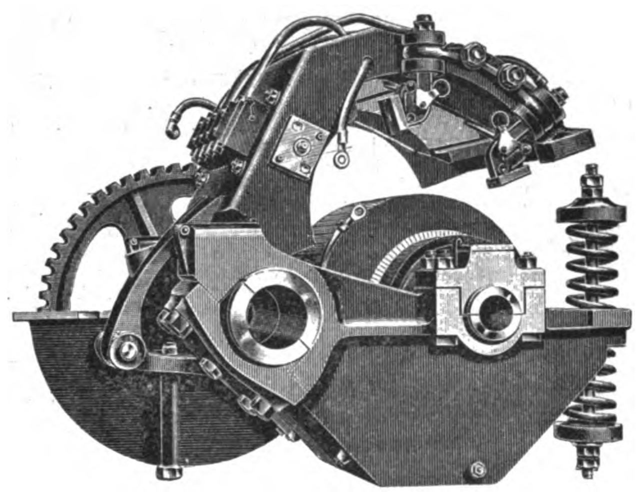


Electric Locomotive for the B. & O.

THE GRÜTSCH & MÜRREN ELECTRIC RAILWAY IN SWITZERLAND.

Concerning the electric railway recently built near Lauterbrunnen, Switzerland, 5,000 feet above the level of the sea and commanding a view of the magnificent Jungfrau chain, *Industries* makes moan as follows: "It would seem that the Swiss are bent upon spoiling their country as much as possible. Whenever they find an inaccessible precipice they run a railway up it. They are proposing a railway up the Jungfrau itself. The Philistinism of the American who was shocked at the bad engineering of the Tower of Pisa, and who sent in an estimate for making it vertical, pales before that of the Swiss railway projector."

We quite agree with our contemporary that there are places where railways of any kind are out of place, especially on the faces of "inaccessible precipices;" still, if the grandeur of the Swiss scenery is to be eclipsed by impossible examples of engineering skill, it is, perhaps, well that the latter should be constructed in a manner worthy of their surroundings.



The Oerlikon Railway Motor.

The road in question was built by the Oerlikon Company and is of the ordinary single trolley system. The generators employed are multipolar machines with drum armatures, with the conductors connected across so that two brushes can be used. The lower part of the field magnet is cast on the bed-plate, and the bearings are mounted on round-footed pedestals which fit upon surfaces bored at the same time as the field magnets.

The type of motor used is shown in the accompanying illustration. The field is made of two steel castings for the sake of lightness and compactness. A single reduction gear working upon a four inch axle is employed. The field magnet coils are wound on strong insulating material compressed in special moulds. The armature is wound with embedded wires. Notches are employed with openings sufficiently large to admit the wire without threading, several wires being arranged in each notch; and carbon brushes are employed.

The axle gear is of steel, with a phosphor-bronze pinion having teeth of a new shape which are said to work noiselessly and without "play." The motor is mounted on a truck with 30-inch wheels, and its lowest point is 3¼ inches above the level of the top of the rails. The length is also small, so that a pair of motors can be easily mounted on a bogie with a five foot wheel base.

The controlling gear has a double motion, and is designed for a 600-volt circuit.

FROM BUFFALO TO NIAGARA BY ELECTRIC CAR.

The Buffalo and Tonawanda Electric Railway Company has filed its papers of incorporation. The company will build an electric railroad, four miles long, beginning on the Military Road at the city line of Buffalo, and terminating at the northerly line of North Tonawanda. The capital stock is fixed at $100,000, consisting of 1,000 shares of $100 each. The directors for the first year are: Frederick Swift and Wendell Goodwin, New York; G. H. Wirth, Brooklyn; W. P. Whitlock, Elizabeth, N. J.; L. P. May, New York; Francis Gilbert, East Orange, N. J.; the Hon. W. Caryl Ely and Frank A. Dudley, Niagara Falls, and Charles A. Leh, New York. This railway is a part of the line which, in connection with the North Tonawanda Electric Street Railway and the Niagara Falls and Suspension Bridge Street Railway, is to form a through line from Buffalo to the Falls, the tracks of the last named companies being used by virtue of a traffic arrangement just made. When completed the road will be one of the longest electric railways in the United States and will run through a well populated and growing country which, with the using of power from the Niagara Falls Power Company as intended, should make the road a very profitable one.

MORE ELECTRIC CARS FOR NEW ORLEANS.

PRESIDENT H. M. LITTELL of the new Electric Traction Company formally took charge of the company's property in New Orleans on Jan. 13. President Joseph A. Walker of the New Orleans City and Lake Railroad turned over the affairs of the company to the purchasers, represented by Mr. Littell. The property consisted of 66 miles of street railroad, 182 cars, 867 mules, seven dummy engines, 36 passenger coaches and other cars. Some $200,000 in cash and stock were also included in the transfer.

The Traction Company has virtually been in charge since the 1st of January.

The City Railroad has been in existence since June 5, 1860, and its history justifies the confidence in the reward for enterprise to be obtained in New Orleans. Col. Joseph A. Walker was elected president, and has served the company for twelve years. During his administration the West End has been improved. The Prytania and Magazine St. lines have been extended, the property of the company bettered in every way, the debt paid off, a surplus of $200,000 secured, and the stock finally sold to the Electric Traction Company at $150 a share. In a few days the electric concern will form its plans and work will be begun without delay.

The Prytania street line will be the first to be converted into an electric system, and the others will be constructed as rapidly as possible. It is proposed to build the roadbed in the most solid manner, and to equip the tracks and every branch of the new service with the best and most modern accessories.

NEW ELECTRIC RAILWAY IN PHILADELPHIA.

MAYOR Stuart, of Philadelphia, having signed the ordinances for The Elmwood and Fairmount Park, and The Fairmount Park and Haddington roads, they will be the pioneer roads in Philadelphia to be equipped with electric motors, among the many suburban roads now projected. Though the Bainbridge street line has been equipped and is now in operation with the "trolley" system, yet these two roads will be the first which will have the official sanction of the Mayor of Philadelphia, and it is proposed by the Directors to construct and equip them as model suburban roads.

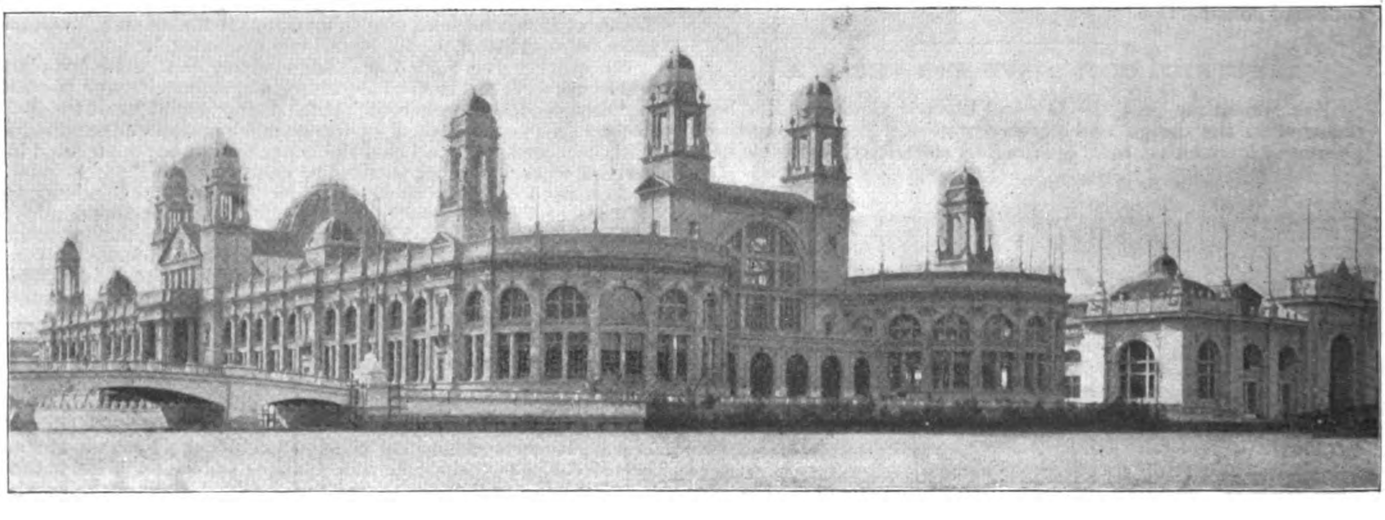
The entire lines with extensions will be some sixteen miles in length and it is proposed to begin operations in June with about twenty cars. The lines will form a connecting link between the large territory lying South and West of the 52d Street station of the Pennsylvania Railroad, and the lines of the Traction Company and of the Pennsylvania Railroad Company, with a branch to George's Hill, Fairmount Park.

The entire construction and equipment of these roads has been placed in the hands of the Neftel & Marsh Company of New York.

WORLD'S FAIR DEPARTMENT.

A FEW DETAILS ABOUT THE WORLD'S FAIR LIGHTING.

AROUND the Grand Basin of the Chicago World's Fair are grouped nearly all of the largest and most important of the exhibit buildings. Across the east end stretches the long colonnade of the Peristyle with the great arch of the Porticus Columbus in the centre. On the north side are the Music Hall and the shorter facades of the Manufactures, Electricity and Mining buildings. At the west end, the head of the basin, stands the Administration building, and on the south side the Casino, Agricultural and Machinery buildings.



ELECTRICITY BUILDING, WORLD'S FAIR, CHICAGO.
(Photographed from the Water Front.)

The cornices of these buildings on the side fronting the basin and the South Canal are outlined with incandescent lights. Those are of 16 c. p., and are placed two feet apart, and at such an angle as to give the most effective results as seen from below. A series of experiments was made to show the best spacing and angle, and it was found that lights at intervals of two feet and set at an angle of 30 degrees from the horizontal would be the most satisfactory. There are about 4,800 lights used on the cornices of these buildings distributed approximately as follows:—Peristyle, 300; Music Hall, 100; Manufactures, 500; Electricity, 350; Mining, 200; Administration cornices and dome, 1,500; Machinery, 950; Agriculture, 800; Casino, 100. A special porcelain socket is used for these lights, provided with insulating feet to raise it above the surface of the roof. The wires are strung from one socket to another and have no other supports nor insulators, the socket answering for both. These sockets have been subjected to severe tests, such as being operated for some time with both lamps and sockets entirely immersed in water without rubber shields or other protecting devices, and have proved quite satisfactory. The circuits on the cornices are sub-divided so that nowhere are there more than about twenty lights on one fuse. The feeders supplying these lights are run on glass insulators inside the hollow walls of the buildings, doors being provided to render them accessible at all times for inspection and repair.

The Peristyle is a long colonnade of lofty columns fifty feet in height, which divides the Grand Basin from Lake Michigan, and connects the Casino Building with Music Hall. The columns are arranged in four parallel rows, the spaces between forming a grand promenade. In the richly paneled ceiling sixty feet above the floor hundreds of incandescent lights are arranged singly and in clusters according to the architectural requirements. Owing to the great height above the floor which renders them inaccessible from below, special means of reaching them to renew burnt out lamps were required. The single lamps were arranged to be withdrawn from above, and clusters are disconnected at the cut-out above and lowered to the floor. To supplement these ceiling lights and also to produce certain desired effects, a vertical row of lights is placed in one of the deep flutes of each column on the side towards the centre passage. The flutes in which the lights are placed are so deep as to entirely hide the lamps from the view of a person standing at one end of the passage, only the bright glow being visible. The Columbus entrance, as the grand arch over the inlet which connects the waters of the Basin with those of Lake Michigan, is called, is finely treated with lights set in the panels, the reflection in the water below adding to the beauty of the whole.

On each side of the Basin at a grade somewhat lower than that at which the buildings are placed is a broad terrace tastefully laid out in flower beds and adorned with fountains and statues. These flower beds are to be outlined with lights set in the grass 12 inches apart. About 2,500 lamps of 10 c. p. will be required for this purpose. They are wired in such a way that they can be readily taken up and replaced when it is necessary to mow the grass.

Not the least among the beautiful light effects that will invite the admiration of the beholder, will be those introduced on the walls of the Basin itself. These walls are perpendicular and are built of piles and planking covered with staff in such a manner as to give them the appearance of having been built of hewn stone. The broad capstone of this wall projects over some five or six inches, and under this "nosing" is placed a row of lights 18 inches apart and at an angle of 45 degrees. This row of lights runs entirely around the Basin on docking and bridges, being broken only at the places where the broad stairways descend to the boat landings.

It is when we reach the upper end of the Basin directly in front of the Administration building that we come to the spot that will attract crowds by day and about which at night will gather all sorts and conditions of men, women and children in undisguised admiration and open-mouthed astonishment. In the centre stands the beautiful allegorical fountain of McMonnies upon which two powerful search lights will be turned, and on each side of this is a great electric fountain, each containing 152 jets and each illuminated with 18 immense arc lights of about 100,000 c. p. each, requiring 90 amperes of current for their operation. The lights, and the mechanism for controlling the water, are all located under the fountain. The pipes supplying the jets are placed within, and concentric with a larger tube through which the beam of light is thrown. An operator stationed in the tower of Machinery Hall will be in communication with the operators under the fountain and will signal to them the various combinations desired. A main 36 inches in diameter has been laid to supply these two fountains and the central jets will at times reach the enormous height of 150 feet. Without indulging in extravagant language or sentimental gush, it may be said that the effect produced by these 300 colored jets, will be one which once seen will never fade from the memory. Nothing to compare with it has ever been seen, and it is possible that another centennial may elapse before it will be exceeded.

High up on a gilded ball on the dome of the Agricultural building stands the great golden Diana which once graced the top of Madison Square Garden in New York. The dome upon which she stands is surrounded near its top by a low parapet which forms a circle about 30 feet in diameter. Behind this parapet, and about the inner circumference of it, are placed a circle of incandescent lamps provided with reflectors to throw the light upon the figure, the source of the light being invisible from below.

The main principle running through the whole scheme of lighting of the Exposition is that lights should be used only in such ways as will bring out more clearly some peculiar beauty of art or nature. Fancy designs in which the lights themselves are the main objects of attraction have been carefully avoided, and every thing made to harmonize as far as possible with the designs of the artists and architects.

L. W. C.

COMMITTEES FOR THE CHICAGO ELECTRICAL CONGRESS.

At the meeting of the Advisory Council of the Chicago World's Congress of Electricians, four committees were decided upon to take up the active work in connection with preparations for the Congress. These Committees were, the Finance, three members; Executive, five members; Invitations, five members; and Programme and Papers, eight members. Dr. Elisha Gray, Chairman of the Advisory Council, has now selected the following members of these Committees, from the Advisory Council and his local Chicago Committee:

Executive Committee.—Prof. Elihu Thomson, Enos M. Barton G. M. Phelps, F. S. Terry and Prof. B. F. Thomas.

Finance Committee.—B. E. Sunny, Prof. E. J. Houston and W. A. Kreidler.

Programme and Papers Committee.—Prof. H. A. Rowland, Prof. H. S. Carhart, Carl Hering, A. E. Kennelly, Prof. W. A. Anthony, Prof. F. B. Crocker, Prof. E. L. Nichols and Prof. T. C. Mendenhall.

Invitations Committee.—T. C. Martin, Dr. Louis Duncan, Prof. C. R. Cross, T. D. Lockwood and C. H. Wilmerding.

Of all these Committees, and any others that may be formed, Dr. Elisha Gray is a member *ex officio.* He will participate actively in the work of each. It is proposed to establish headquarters for the Congress at Chicago at an early date, at which Mr. R. W. Pope, the secretary of the American Institute of Electrical Engineers, will probably be stationed to carry on all the detail work in conjunction with Prof. H. S. Carhart, the acting secretary.

SOCIETY AND CLUB NOTES.

ELECTRIC METERS BEFORE THE CHICAGO ELECTRIC CLUB.

The meeting of the Chicago Electric Club held on Jan. 14th, was devoted to a description and discussion of meters. Mr. P. J. McFadden read a paper describing the Thomson recording wattmeter. He began by showing what was required in an instrument of this kind to fulfil all demands of practice, and then showed in detail how they had been carried out in the now well-known Thomson meters.

He was followed by Mr. John F. Gilchrist, who had prepared an excellent description of the Edison electrolytic meter, entering into all the details of its construction and operation.

Then came Mr. Chas. Wirt, who described the Aron meter, showing its method of operation and construction, and giving the results of tests which he made on it.

NEW YORK ELECTRICAL SOCIETY.

The 151st meeting of the Society will take place on Wednesday, Feb. 8, 1893, at 8 p. m., at Columbia College, Madison ave., and 49th street.

The evening well be devoted to an experimental and illustrative lecture on "The Telephone, and How We Talk from New York to Chicago."

The subject will be divided in two parts to be given respectively by Mr. J. J. Carty, Electrician of the Metropolitan Telegraph & Telephone Company, of New York, and Mr. F. A. Pickernell, Engineer of the American Telegraph & Telephone Company, (Long Distance Company.)

The following is a synopsis of the lecture:

Part I.—By Mr. Carty: The Nature of Sound and the Mechanism of Speech.—Its Propagation and Reception by the Ear.—The Physiology of the Ear.—The Evolution of the Telephone from the Speaking Tube, the String or Lover's Telephone, to the Electric Telephone.—Description of the Bell Receiver and Battery Transmitter.

Part II.—By Mr. Pickernell. Description of Telephone Lines in Use prior to the Opening of the New York-Chicago Line.—How the Size of the Wire and other details of the Chicago Line were determined.—Description of the Line in detail from Columbia College, New York, to the exchange in Quincy street, Chicago, with Stereopticon Views.

Through the kindness of the Long Distance Telephone Company, the Chicago telephone line has been placed at the disposal of the Society for the evening, and telephone receivers distributed throughout the room will enable the audience to hear speech and music transmitted from Chicago.

Members are at liberty to bring ladies. Cards of admission can be obtained on application to the secretary of the Society, Mr. G. H. Guy, Room 812, No. 203 Broadway, New York.

THE BROOKLYN INSTITUTE OF ARTS AND SCIENCES.—TELEPHONE LECTURE.

On Friday Jan. 21, Mr. Edward H. Lyon, lectured on the Long Distance Telephone at Association Hall, Brooklyn, before the Brooklyn Institute. The lecturer was introduced by Mr. James Hamblet, who presided. Mr. Lyon, with the aid of lantern slides, illustrated the Blake and Bell transmitters, showed telephone circuits. methods of pole construction, cables, the workings of a telephone exchange and the general detail of telephonic communication. He had thrown onto the sheet views showing the points through which the telephone line from Association Hall to Chicago passed, the two last views being the offices of the American Telephone & Telegraph Co., at Chicago.* Following the lecture, communication was established with Chicago, and a member of the Theodore Thomas orchestra played the cornet, the sounds of which were distinctly heard in Brooklyn. The applause at the close of the solo was tremendous; and on Mr. Hamblet's remarking that this was the first time in the history of the world that sound had been transmitted so great a distance to such a large audience, a renewed outburst testified the appreciation of those present at the triumph of engineering skill that had made this possible. At the same moment a concert was given to Chicago by the Phipps Musical & Lyceum Bureau at Union Square, New York, and the Brookly audience was put into circuit. Among those taking part was Harry M. Peckham, a gentleman well known in electrical circles, who gave a whistling solo, accompanied by banjo, every note of which was easily heard both in Brooklyn and Chicago. The portraits exhibited by the lantern were those of W. D. Sargent, J. C. Reilly, J. E. Hudson, J. J. Carty, F. A. Pickernell, Prof. A. G. Bell, and the group taken at the opening of the line last October, with Mr. E. J. Hall in the foreground.

CANADIAN ELECTRICAL ASSOCIATION.

THE above association met at Toronto last week, to carry out the programme printed recently in our columns. An interesting meeting was had, and the papers while not dealing with anything specially new, embodied a number of points of value. There were about 40 members and visitors present, who were entertained by the local Edison Co. and other electrical interests.

ST. LOUIS ELECTRIC LIGHT CONVENTION.

THE new St. Louis Electric Club is making various arrangements for the coming convention, February 28 to March 20. It has been decided to have the Tesla lecture on Wednesday, February 28, probably in the Music Hall. A banquet is proposed for Thursday, but it is to be hoped that the idea will not be pushed. President Ayer estimates that about 300 members and visitors will be in attendance at the Convention.

At the last meeting of the Chicago Electrical Association, the following were installed as officers for the ensuing year: President, Albert Scheible; vice-president, F. S. Hickok; secretary, M. B. Speir; Treasurer, L. G. Bassett. The topic for discussion on February 14, will be "Arc Light Carbons."

LEGAL NOTES.

NO DISCRIMINATION TO BE PERMITTED IN LAMP SALES.

THE policy of the General Electric Company as to sales of lamps was disclosed last week by the following circular issued to supply houses and others by that company:

> *Gentlemen:*—You are hereby respectfully notified that until further notice, orders for incandescent lamps will be filled by us only when coming from actual users of the lamps.
>
> Yours very truly,
> CHAS. T. HUGHES,
> District Manager.

It has been understood that the same policy will be made to apply to other lines, and that the General Company has notified various parties that if it does not get the order for generating apparatus the supply of necessaries to run it, so far as the General Company controls such supplies, will be withheld.

The first definite attempt to put in force such a policy as regards an actual consumer of lamps, has been made in Chicago and appears to have broken down. The Sunbeam Incandescent Lamp Company, of Chicago, which was recently put under a restraining order that prevented sale but not manufacture. The Sunbeam Company had been furnishing lamps to the National Electric Construction Company. The latter being unable to secure lamps from this source, turned to the Edison Company, which refused to sell and issued an announcement that no one else could use Edison lamps but itself.

Thereupon the National Electric Construction Company applied to the courts for protection and relief, and the case came before Judge Grosscup in the United States Circuit Court. The question was argued by Mr. F. W. Parker for the National Company and Mr. Beale for the Chicago Edison Company, the latter stating that it was in no way concerned in the affairs of the General Electric Company but had paid $300,000 for the exclusive right to handle Edison appliances in Cook County.

After argument, Judge Grosscup said: "The court wishes it understood that it will not permit an order to issue from this court to close up the plaintiff's plant or interfere with the use of the appliances it has paid for. The provisions of the restraining order issued recently apply only to the sale of lamps, and I shall refuse to issue an order calculated to discontinue the operation of plaintiff's plant." Judge Grosscup remarked also that if the Edison Company could not supply the National with lamps, he would see to it that the latter could secure a market from which to draw supplies. Hence the National Company will not take Mr. B. E. Sunny's advice to "lay down or sell out" but is adopting his third proposition, of "fighting."

The next day Attorney G. N. Morgan appeared for the National Construction Company, and the only move of importance in the case was made by him when he asked the court for direction as to the means his clients should adopt to relieve themselves from their present need for lamps. The court then said to Mr. Morgan: "If you will apply to the Edison Company for lamps and they refuse to furnish them, or state that they cannot fill your order, I will release the Sunbeam Company to the extent of allowing them to fill the order for you."

"In a few days we may need another supply of lamps," said the attorney.

"Then come to me again and I will see that you get them," replied the court.

The same determination was expressed by Judge Grosscup, to Mr. Parker:

"I think you had better make out a list of all the lamps you need to resume operations and present it to me. I will add to it the number I think a fair one for you to have in stock for changes. Then you may present the order and tender the money to the Chicago Edison Company, and if you do not secure your lamps the court will take action."

THE Chicago *Evening Post* of January 26 says:—

After leaving Court Attorneys Parker and Morgan, for the National Electric Construction Company, appeared at the local offices of the Edison Company and made their demand for incandescent lamps at 42 cents apiece. The Edison people demanded 50 cents and would go no lower. Then the attorneys served notice that the matter would be brought before Judge Grosscup this afternoon to compel the Chicago Edison Company to sell lamps at 42 cents. At 2 o'clock the Edison Company gave in and its representative sent word to Attorney Morgan that the National Electric Construction Company could have any number of lamps at 42 cents each for an indefinite period. This is considered as a great victory for the anti-combine people.

IN order that it may spot consumers of lamps other than those of Edison make, and it would appear, to draw the trade wholly into its own hands, the General Electric Company has sent out a reply postal card, to every known user of incandescent lighting. It runs as follows:

> HARRISON, N. J., Jan 25, 1893.
>
> ON the attached card, we give information regarding your plant, according to our statistics.
>
> As we are very anxious to test the accuracy of our records, we would be pleased to have you verify the same, and if correct kindly return to us. If incorrect, we would be pleased to receive any remarks you may be kind enough to make.
>
> If you do not wish to oblige us in this matter, please return the card, so that we may know you have received it.
>
> Very truly yours.
> EDISON GENERAL ELECTRIC COMPANY.
> Lamp M'f'g Dept.

The information sought on the card is as follows: "Name; address; business; kind of plant; estimated capacity of dynamo, and maker; plant, when installed; estimated number of 16 c. p. lamps connected; other candle-power lamps; voltage; approximate number of Edison lamps consumed years ending 1889, 1890, 1891; Remarks: Correct except as to." Across this in one corner is written: "We would be pleased to have blank spaces filled in. E. L. W."

INCANDESCENT LAMP LITIGATION.

THE GOEBEL DEFENCE.—EDISON ELECTRIC LIGHT COMPANY (GENERAL ELECTRIC COMPANY) *vs.* BEACON VACUUM PUMP AND ELECTRICAL COMPANY IN U. S. CIRCUIT COURT, BOSTON, JAN. 24 AND 25.

Counsel present for complainants, F. P. Fish, C. E. Seward, and R. N. Dyer. For defendant. L. D. Brandeis, W. C. Witter and W. H. Kenyon.

UPON the opening of court Tuesday morning, January 24, Mr. Witter resumed his reading of the affidavits presented for the defence, commenting upon the corroboration of the details of Goebel's story found in them, and interspersing his reading and comment with argument from the facts shown. He dwelt especially upon the undoubted filamentary character of the carbon conductor in the Goebel lamp exhibited to the court and which was stated by the experts to be from 8 to 10 thousandths of an inch thick—or only half the thickness of the filament shown in the Edison patent.

MR. WITTER presented an affidavit of H. S. Kaliske, business manager of the Beacon Company, stating the capacity of its lamp factory as 3,000 per day, and denying that, as alleged by the prosecution, the company had accumulated a lamp stock ahead and was running the factory night and day. He also read the deposition of D. C. Voss. Mr. Voss being in Boston had heard of the hearing in the present case and came into court as a spectator. Having been employed in the American Company's shop under Mr. Crosby in 1881 and 1882, and finding the Goebel matter up as a defence, he offered his testimony to the defendant's counsel. Mr. Voss testified that he knew Goebel as early as 1874 or 1876, and he corroborated many points of the statements in the affidavits of Henry Goebel and others.

Complainant's counsel read affidavits in rebuttal. They were by Prof. Elihu Thomson, John W. Howell and John E. Randall.

Prof. Thomson, in his affidavit, said that he had read the affidavits of Henry Goebel, F. L. Pope and C. R. Cross and had heard read many other affidavits produced by defendants. He had also examined the three lamps exhibited. He remembered Goebel as far back as 1881 or 1882 and thinks he saw him then. Goebel was then employed by the American Electric Light Company in New York, which company had been started by Mr. Crosby (whose affidavit was filed in this case) and a Mr. Fox; it afterwards combined with the Eastern Electric Manufacturing Company—owning the Sawyer-Man patents—forming the Consolidated Electric Light Company. The manufacture of lamps was afterwards turned over to the Sawyer-Man Company which company had recently been enjoined by the U. S. Court of Appeals in New York. Prof. Thomson had visited Goebel's shop in 1881 or 1882. He had little faith in the Goebel story at the time, although the officials and employés of the American Company expressed their reliance upon it as a defence against the Edison patent. He felt sure the three lamps now exhibited were never practically operative; they might have burned a little, but the Goebel lamps could never have been practically used. They could not hold a vacuum for any considerable period; leaks would at once develop around the sealing-in of the iron and copper leading-in wires.

Mr. Howell and Mr. Randall, technical experts of the Edison Lamp Works and Thomson-Houston Lamp Department, respectively, in their affidavits said that they had examined the Goebel lamps exhibited and had read Prof. Thomson's affidavit and that they concurred with everything that he had stated as to the structure and effects of the exhibits.

Respecting the alleged knowledge of Goebel and his work on the part of the defendants in the New York suit (the United States Electric Lighting Company) and their failure to allege prior use by Goebel as a defence, Mr. Witter read an affidavit of Mr. Leonard Curtis, who had charge of the United States Company in that case.

Mr. Curtis states that he first heard of Mr. Goebel in connection with incandescent lamps in the early part of 1882. He saw him then at his office in New York, and in answer to questions Goebel stated that he had made incandescent lamps like Mr. Edison's as early as about 1850. He thought that some one interested in the United States Company sent Goebel to him. He endeavored to go over the matter at considerable length but had much difficulty in understanding Goebel who spoke and understood English very imperfectly. He understood him to say that he had made lamps as early as 1850 and had operated them with a battery in his laboratory or shop in New York, and that a considerable number of people had seen them in operation. He was impressed at the time with Goebel's apparent truthfulness. He did not ask for any compensation for the information and did not seem to expect any advantage for himself from it. He did not gather from Mr. Goebel at any time the impression that he had made any use of the lamps except for experiments, nor that his work was continued for more than a year or so after 1850, nor did he succeed in getting track of witnesses to corroborate Goebel's statements. He was led to drop the matter at the time through his erroneous impression that Goebel's work had been entirely discontinued and abandoned within a year or two of 1850.

When the answer in the United States case was prepared he consulted with General Duncan about Goebel's statements and both concluded that it would not be worth while to put the Goebel matter in the answer or to look it up further, believing his work to have been abandoned in 1852 or thereabouts. He heard nothing further about Goebel's work until the closing of the proofs in the United States case. He then learned from J. Edgar Bull that the latter had seen one of Mr. Goebel's sons who corroborated his father's statements. He was also informed then for the first time that some of the original lamps might be in existence. He and General Duncan concluded, however, that the evidence then obtainable was not sufficient to warrant application to the Court to re-open the case, nor did he know at that time that any evidence existed for other or longer use of lamps than that before stated.

Mr. Curtis further states that the Goebel matter was again looked into in connection with the Sawyer-Man case, with some prospect of obtaining additional evidence; but counsel concluded that the time at their disposal on the injunction motion was too limited for looking the Goebel matter up. He did not know, nor so far as he was aware, did either of the counsel for the defendants in these prior cases, at any time during the progress of the litigation when the evidence could be availed of, that evidence of anything like the character and extent now presented in this case respecting Goebel's work was obtainable or existed. He had no hesitation in saying that counsel would have presented this evidence in the cases referred to if they had known of it in time.

Mr. Kenyon followed Mr. Witter and occupied the short interval left before adjourment at 4 p. m. The court arranged with counsel that the hearing should be concluded the next day.

Wednesday morning Mr. Kenyon resumed his argument. His address consisted largely of citations and quotations from documents in the previous suits on the Edison patent, and from the opinions of the courts in those cases, tending to establish mainly the proposition that in 1879 when Mr. Edison succeeded in making a commercial lamp, the state of the art as generally known included every requisite element save the filamentary carbon. He quoted at length from the opinon of Judge Wallace in the United States Co. suit, and from the decision of the Appellate Court. The evidence submitted in the present suit, said Mr. Kenyon, showed that the characteristic and necessary feature of the combination set forth in the second claim of Edison's patent, was anticipated many years by the use of Goebel.

Mr. Brandeis followed in further argument for the defendant, setting forth the irreparable injury to his clients that would follow an injunction, and their abundant financial responsibility for any damages that might be adjudged against them after a final hearing.

Mr. Seward then spoke for the complainants. He said a patent was a contract with the Government. The defendant did not deny infringement of the Edison patent as interpreted and adjudicated by the court of last resort, but set up an improbable and unconvincing story of prior use. A preliminary injunction should therefore be granted.

Mr. Fish made the closing argument for the complainants. A fundamental fact, he said, appeared clearly throughout the litigation of the Edison patent, and it would, he believed, control to the end. That was, that Mr. Edison gave to the world a new art. There had been no controversy as to that.

Until 1879 or 1880 it had been impossible to obtain an incandescent lamp by purchase, or to use one commercially. The United States intended that Mr. Edison should profit by his invention, but up to this day the patent had afforded absolutely no protection to him. Notwithstanding the judgments of the Court of Appeals in New York, upon the merits and equities involved, and the injunctions and restraining orders granted elsewhere, these defendants asked his Honor to stay his hand, saying that the New York decision was wrong. Mr. Fish then cited a large number of cases, quoting copiously from the language of the courts, tending to show that in analogous cases it had always been held that a prior invention or a prior use, to defeat a patent, must be proved beyond a reasonable doubt, and that considerations of probability would often outweigh a preponderance in number of witnesses and explicit statements made by them. In this case, he said, the defence say: "If your Honor is doubtful give us a chance to prove this thing before you grant an injunction." ~~We say~~: "Unless your Honor is sure, give us the injunction." The story was intrinsically more improbable than the Drawbaugh narrative in the telephone case. The production of 26 witnesses, at short notice, to the Goebel use on the public streets of New York over 30 years ago, and on from year to year, fairly means, that there were 26,000 who knew about it. The whole story could not be true. How much truth there was in it Mr. Fish did not know and the Court would probably never find out without a most extensive examination and cross-examination of witnesses. On the face of the affidavits he held that only the crudest and baldest kind of experimenting was shown, and no such use, in a commercial sense, as must be required to defeat a patent. Experiments might last 40 years as well as 40 minutes. Mr. Curtis's affidavit was entitled to the fullest credence of the Court, his distinguished ability and his entire integrity were well known to his brother lawyers.—Was it not exceedingly improbable that one so competent, managing the defence in the United States Company case—a sleuth-hound in ransacking every nook and cranny for evidence—should fail to get at all the facts in the Goebel story? After extended criticism of the affidavits and the exhibits of the defendants, Mr. Fish closed by asking that an injunction be granted, and admitting the seeming impropriety of asking the Court for special despatch, hoped his Honor would act with the greatest promptness consistent with the convenience of the Court.

The Court then announced that one week would be granted for printing the papers in the case and for the filing of briefs by counsel on both sides.

THE LATEST ELECTRIC LIGHT.

Mr. Henry Goebel gave an exhibition of his electric light last night in a room back of his store at 468 Grand street. Mr. Goebel claims that he has been at work on electric lights for 31 years and that 29 years ago, he arranged one on the top of his house at 271½ Monroe street. The light was seen from the Essex Market bell-tower and an alarm of fire was given, which brought out a number of engines. He himself was arrested, but Judge George Woods released him. When he had returned home he found that his neighbors had demolished all his instruments and apparatus. The light exhibited last night was clear and steady, and one could read by it with great comfort and ease. It is about 8 inches long and about as thick as a candle. The vacuum is obtained by a pump similar in principle to the Gessler (sic) pump and can be operated by unskilled hands. The carbon points used are made of reeds which are heated in the retort by electricity. The lamps cost 25 cent apiece and Mr. Goebel claims that he can furnish light as cheap if not cheaper than gas.—*New York World*, May 1, 1882.

MISCELLANEOUS.

THE PHYSIOLOGICAL AND OTHER EFFECTS OF HIGH FREQUENCY CURRENTS.

BY

Nikola Tesla

IN THE ELECTRICAL ENGINEER of January 25, 1893, I note an article by Mr. A. A. C. Swinton, referring to my experiments with high frequency currents. Mr. Swinton uses in these experiments the method of converting described by me in my paper before the American Institute of Electrical Engineers, in May, 1891, and published in THE ELECTRICAL ENGINEER of July 8, 1891, which has since been employed by a number of experimenters; but it has somewhat surprised me to observe that he makes use of an ordinary vibrating contact-breaker, whereas he could have employed the much simpler method of converting continuous currents into alternating currents of any frequency which was shown by me two years ago. This method does not involve the employment of any moving parts, and allows the experimenter to vary the frequency at will by simple adjustments. I had thought that most electricians were at present familiar with this mode of conversion which possesses many beautiful features.

The effects observed by Mr. Swinton are not new to me and they might have been anticipated by those who have carefully read what I have written on the subject. But I cannot agree with some of the views expressed by him.

First of all, in regard to the physiological effects. I have made a clear statement at the beginning of my published studies, and my continued experience with these currents has only further strengthened me in the opinion then expressed. I stated in my paper, before mentioned, that it is an undeniable fact that currents of very high frequency are less injurious than the low frequency currents, but I have also taken care to prevent the idea from gaining ground that these currents are absolutely harmless, as will be evident from the following quotation: "If received directly from a machine or from a secondary of low resistance, they (high frequency currents) produce more or less powerful effects, and may cause serious injury, especially when used in conjunction with condensers." This refers to currents of ordinary potential differences such as are used in general commercial practice.

As regards the currents of very high potential differences, which were employed in my experiments, I have never considered the current's *strength*, but the *energy* which the human body was capable of receiving without injury, and I have expressed this quite clearly on more than one occasion. For instance, I stated that "the higher the frequency the greater the amount of electrical energy which may be passed through the body without serious discomfort." And on another occasion when a high tension coil was short-circuited though the body of the experimenter I stated that the immunity was due to the fact that less *energy* was available externally to the coil when the experimenter's body joined the terminals. This is practically what Mr. Swinton expresses in another way; namely, by saying that with "high frequency currents it is possible to obtain effects with exceedingly small currents," etc.

In regard to the experiments with lamp filaments, I have, I believe, expressed myself with equal clearness. I have pointed out some phenomena of impedance which at that time (1891) were considered very striking, and I have also pointed out the great importance of the rarefied gas surrounding the filament when we have to deal with currents of such high frequency. The heating of the filament by a comparatively small current is not, as Mr. Swinton thinks, due to its impedance or increased ohmic resistance, but principally to the presence of rarefied gas in the bulb. Ample evidence of the truth of this can be obtained in very many experiments, and to cite them would be merely lengthening this communication unduly.

Likewise, observations made when the experimenter's body was included in the path of the discharge, are, in my opinion, not impedance, but capacity, phenomena. The spark between the hands is the shorter, the larger the surface of the body, and no spark whatever would be obtained if the surface of the body were sufficiently large.

I would here point out that one is apt to fall into the error of supposing that the spark which is produced between two points on a conductor, not very distant from each other, is due to the impedance of the conductor. This is certainly the case when the current is of considerable strength, as for instance when, like in the Faraday experiment or some of Dr. Lodge's, a heavily-charged battery of Leyden jars is discharged through a bent wire. But, when there is a vibration along a wire which is constantly maintained, and the current is inappreciable whereas the potential at the coil terminal is exceedingly high, then lateral dissipation comes into play prominently. There is then, owing to this dissipation, a rapid fall of potential along the wire and high potential differences may exist between points only a short distance apart. This is of course not to be confounded with those differences of potential observed between points when there are fixed waves with ventral and nodal points maintained on a conductor. The lateral dissipation, and not the skin effect, is, I think, the reason why so great an amount of energy may be passed into the body of a person without causing discomfort.

It always affords me great pleasure to note, that something which I have suggested is being employed for some instructive or practical purpose; but I may be pardoned for mentionting that other observations made by Mr. Swinton, and by other experimenters, have recently been brought forward as novel, and arrangements of apparatus which I have suggested have been used repeatedly by some who apparently are in complete ignorance of what I have done in this direction.

ELECTRICAL RECORDING METERS.—II.

BY CARYL D. HASKINS.

There is another device, or perhaps I had better say there might be another device for accomplishing the object of this last meter in a somewhat similar manner. The actinometer is probably familiar to all who have indulged in amateur photography; it consists of a piece of glass covered with small cubes, each cube of a more intense ruby red than the one beyond it, merging, in fact, from an almost clear glass to an almost perfectly non-actinic medium. Now, it suggestd itself to a certain electrician that if a number of these squares were arranged in a piece of glass, one above the other, and a lamp whose light should vary more or less directly with the potential on the lines, be placed before this glass or actinometer, a sensitive film being rotated behind the actinometer at a constant speed, that the varying light of the lamp would draw a curved line, or rather a curved block of light and shade on the paper, which would be measured by a planimeter to get the average voltage, or could be taken at points, to see what the voltage was at certain times; in fact, a recording voltmeter. This device seemed very nice indeed. It had only one fault—it would not work. I might say that the device is my own.

There is almost an endless variety of clock meters. They are not all electricity meters by any means; some are recording voltmeters, others recording ammeters, and others have still different purposes. The familiar recording steam gauge is only a modification of this instrument. A paper is almost invariably rotated over a drum, sometimes being fixed to the drum, and sometimes being drawn from one drum to another, the paper moving at uniform speed, and generally being divided into hours or other fractions of time by abscissæ lines.

This clock mechanism can be combined with any indicating device; it is only necessary to supply the connection which shall cause the indicator to mark the paper, and draw a crooked line. First attempts of this kind are generally made with an ordinary solenoid, or sometimes with a simple coil and iron core rising and falling with the current. Whatever the character of the indicator or method of communication between the indicator and paper, it remained necessary to keep the friction of contact low.

First attempts were made with a pencil, bearing directly upon the paper, but the friction introduced by this device was fatal to accuracy. A glass pen has been substituted for the pencil with better results, but even this caused too much friction. The photographic method of line drawing is one of the best systems yet introduced, and is probably more familiar to the majority of us than other methods, because it forms a component part of the Walker meter which has attracted attention at various times.

One of the best methods of accomplishing the registration, perhaps, when all things are considered, the very best, is to attach to the pointer of the indicator, a steel point or needle with an iron armature mounted in the form of a spring, or in some similar manner. By placing an electromagnet behind the paper to be marked, and sending through this magnet an electrical impulse at fixed periods of say, one, two or five minutes, the pointer is drawn sharply down to the paper, puncturing it, and is immediately released by the cessation of energizing current in the electromagnet. Thus, the paper when removed, will have a continuous marking of punctures tantamount to a curved line. This device presents practically no friction, and is more or less simple and easy to carry out. The make-and-break necessary for the electromagnet is easily actuated by the clock movements. But we may say of these forms, as well as of the forms of clock meter which are to follow, that there is one serious objection to them all—they have to be wound up, which is certainly a fault. We may modify this statement by saying that many of these devices have an electrical attachment which makes them self-winding, and this is a step in the right direction at least. Whether it fully meets commercial necessities, is, I believe, an open question.

All of these instruments being curve-drawing meters, they cannot properly be considered as the thoroughly commercial article, which the successful electric meter must be. For, I think I am safe in assuming that to be successful the meter of to-day positively must have a direct reading dial, equally available for the consumer and supplier.

This brings us to a second form of clock meter of a preferable character. This class comprises those meters whose clock mechanism is accelerated or retarded by the strength of the current passing through them. There are several methods of accomplishing this, all of which apply the influence of the current to the pendulum of the clock. For example, we have a pendulum with an iron end forming an armature which is attracted first to the right, and then to the left by two electromagnets dependent for their strength upon the lamp circuits. This is an early and very ineffective form of clock meter, hardly to be considered as a practical affair, but typical of the class.

The most successful and probably the best form of meter of this kind consists of two clocks with a differential gear between. One of these clocks runs at a constant speed, the speed of the other being governed by the circuit to be measured. At times by a shunt pressure coil forming an armature, and a fixed series coil forming a field, or again, by a horseshoe magnet pendant from the pendulum and vibrating back and forth above two coils in series with the lamps, the former being a watt-meter and the latter an ammeter. Both were designed by the same inventor. When nothing is passing through the meter, the speed of both clocks is the same, and the differential gear does not move; but when lamps are turned on, and the regulating device begins to act, one clock is accelerated or retarded according as the principle may be applied, and the difference between the constant speed clock and the varying speed clock indicates the consumption in directly read units.

I can safely say that this is an excellent meter, but is obviously open to the same objection as are other clock meters, since there are two clocks and the presence of the differential gear requires very nice adjustment between the two. There is another important factor here, which bears directly upon the question in hand, and that is, the cost of building meters of this class. The clock-work must not be of a cheap character, but must be good clock-work and good clock-work is invariably expensive, and is invariably delicate.

I might say, however, that the Aron meter, the typical meter of this type, proved itself so accurate at the recent meter competition in Paris, that it succeeded in dividing the first prize of 10,000 francs and a gold medal, with the Thomson recording watt-meter, the principle of which we shall consider later. Your attention may be directed to the fact that the Aron meter is a watt-hour indicator, something unusual, for almost everything considered up to the present point has been typically an ammeter or a modification of an ammeter.

Before turning to the final portion of this paper and considering the most popular and as yet the most successful class of recording instrument, viz., the motor meters, a little attention should be given to those clock meters, whose principle is dependent upon the function of a cone or cones. There are a considerable number of meters of this class. It appealed to the inventive mind early, and our patent records are full of cone meters.

Briefly, the principle of all of these instruments is about as follows:—Let us assume a wheel rotating at a constant speed; let us assume a cone mounted on a shaft on which it is free to rise and fall; let the cone rise and fall with one of its sides in a vertical plane with the periphery of a constantly rotating wheel; the speed of the cone regulates the speed of rotation of the recording gear and the position of the cone is determined by an indicator device which obviously must be of high torque, because friction must be a more or less serious factor. Some very fair instruments of this class have appeared from time to time. One of the most ingenious of them provides two cones, or rather two cone-like drums, somewhat like a beehive in shape. One of these cones is rotated at a constant speed, and the other is inclined on a movable right angle axis in such a way that its point of contact with the neighboring cone varies with the load. The same end is accomplished as that in the rising and falling cone just described without the introduction of as much friction. This is a type of the Maxim meter. Another similar device provides for a small wheel rising and falling between two cones whose inner sides are parallel, thus transferring the power from a constantly rotating cone, to a cone with varying speed, the same object and end being accomplished in all cases, and invariably involving friction.

Another form of cone meter, still a clock meter, differs somewhat from those just described. Let us assume a conical drum, shaped like the bullet of an ordinary rifle, and some four or six inches in diameter at the base, rotating at a constant speed by a clock mechanism beneath it; let us suppose a spool of thread to be placed upon a pin a foot or so removed from the drum; the thread from the spool is attached to the drum which should be covered by some felt-like material; the thread passes through an eye or ring which in its turn is attached to an indicating mechanism. It is apparent that the indicator will raise and lower the spring according to the amount of current or energy passing. Since the drum rotates at a regular speed, the thread will be wound onto the drum and the point where it is wound on will depend on the position of the indicator. Thus, if the load were very small, the indicator would be at its highest point and the thread would be wound around the smallest diameter of the drum. As the load increased, the indicator would be depressed and the thread would be wound on a greater diameter of the drum. The inspector of meters, on his monthly visit, would remove the thread which had been wound onto the drum, measure it on a yard stick, and ascertain perhaps that the consumer had used 15 yards of electricity. This is certainly reducing things to a very practical standpoint.

In conclusion, I would say of the clock meters, that those which actuate a drum or marking mechanism, and those akin to them, generally have a stopping and starting device which prevents the clock from running at times when there is no current passing through the meter; this is quite essential. Those which have a lamp within them for photographically marking the fluctuations of current, have an automatic cut-out for the lamp, which turns out the light in the meter when the last lamp on the supply circuit goes out. I might add that in a few of these meters the clock is displaced by a constant speed motor.

LUMINOUS DISCHARGES.[1]

BY E. C. RIMINGTON.

As the illumination of electrodeless vacuum tubes has been brought forward rather prominently during the past year, principally through the experiments of Tesla, the writer, in response to the request of the editor for a short article, thinks a few words on the subject may prove of general interest.

The cause of the illumination of an exhausted tube is a suddenly-acting electric stress in the dielectric, formed of the rarefied gas inside the tube; if the stress be great enough and applied with sufficient rapidity, the rarefied gas, being a weak dielectric, gives way, and a convection current passes in the tube. The luminosity produced is probably due to the molecules of the gas colliding with increased velocity, these collisions causing the molecules to vibrate in parts (somewhat analogously to the prongs of a tuning-fork), and to give out ether waves short enough to affect the retina of the eye; or it may be that the electric equilibrium of the molecules is upset by these collisions, and their charges caused to oscillate, thus giving out electromagnetic waves of short enough wave-length to be called "light." The effect just described may be produced in three ways.

1. By placing an exhausted tube in a rapidly-varying electric field. This is what happens when a vacuum tube is held near an influence machine which is sparking between its knobs, or in the vicinity of an induction coil whether the latter be sparking or not. If two metal or tinfoil plates about two feet square are suspended about eight or nine feet apart and connected to the terminals of a five and a half inch spark coil, a tube five feet long and about two inches in diameter will glow brilliantly when places anywhere between the plates.

2. By rotating a tube in a constant electric field, thus varying the electric induction through the tube. This effect was recently shown by the writer in conjunction with Mr. Wythe Smith before the Physical Society.

3. By rapidly varying the magnetic induction through the tube, which results in an electric stress at right angles to the magnetic induction. This can be done by wrapping a few turns, or even a single turn, of guttapercha-covered wire round the tube, and discharging a Leyden jar through this wire; a sharp and brilliant luminous discharge will be seen in the tube close to the wire. This discharge can be shown to possess all the magnetic properties of an electric current. The effect is in the main as described above, but is slightly complicated by electrostatic action, particularly in the case where the discharge is feeble, but space will not allow the writer to more than allude to this.

THE GREEN ELECTRIC RAILWAY PATENTS.

THE following dispatch from Springfield, O., of Jan. 29, is printed for what it is worth. The General Electric Company has confirmed it as we go to press, in its broad features:

> It is reported that O. S. Kelley of this city has sold his patent on the overhead electric trolley system to the General Electric Company of New York City. A friend of Mr. Kelley states that the rumor is true and Mr. Kelley has received a sum running up into the hundreds of thousands for his patent.
>
> A man named Green is the inventor of the patent held by Mr. Kelley. Green was poor, and Mr. Kelley furnished him funds for 20 years to prosecute his claims in the Patent Office at Washington. Two years ago the Supreme Court of the District of Columbia handed down a decision sustaining the validity of Green's invention, and Mr. Kelley bought him out. The patent covers all systems using the overhead trolley.

LETTERS TO THE EDITOR.

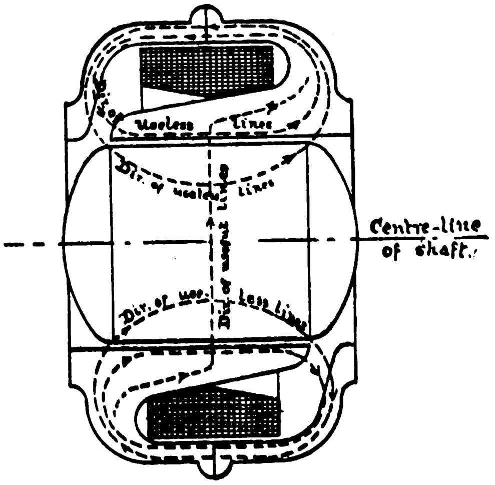
THE DESIGN OF THE LUNDELL MOTOR.

ALTHOUGH Mr. Lundell has taken recourse to personalities and insinuations, instead of reasoning, in his answer in THE ELECTRICAL ENGINEER of Jan. 11, 1893, I would like to point out some fallacies in his arguments and claims.

Mr. Lundell compares two well known types of motors, one shown in his Fig. 1, which may be called the Silvanus P. Thompson type, and the other in his Fig. 2, which may be called the Eickemeyer type, and shows the latter type to have a much longer wire per turn in the field coil; but he does *not* show what the more important gains are, which more than compensate for the increased length of wire per turn. Since the direct magnetizing of the armature and polepieces, which minimizes the leakage of lines of force in the field, is the only advantage the Eickemeyer type has over the Thompson type, I will, for the sake of argument, assume that said advantage really compensates for the increased length of wire per turn of the field coil.

Mr. Lundell further says, that the type under discussion (for some reasons *partially* shown in his Fig. 3), has about the same length of wire per turn as the Thompson type, but has been so "simplified and the resistance of the magnetic circuit made so small that the number of turns in the field coil are reduced to a minimum." But he *fails* to show in what respect it has been simplified or how the resistance of the magnetic circuit has been reduced, *more* than can be done in any other good type of motor.

In the description of the Lundell motor in THE ELECTRICAL ENGINEER of Dec. 7, 1892, Mr. Lundell says that "to a large extent the direct magnetization of the armature is also accomplished, so that a considerable economy in the ampere turns of the magnetizing coil is thereby effected;" and it may be inferred from this that Mr. Lundell claims the gain by direct magnetization of the armature also in the type under discussion to more than compensate for the increased length of wire per turn.



Referring to the accompanying figure, which shows more completely the type under discussion, every electrician will understand, that the direction of the lines of force due only to the direct magnetizing of the armature by the field coil would be *longitudinal* and *not crosswise*, as Mr. Lundell "seems to think," and as is the case in the Eickemeyer type, and that those lines would *tend* to leak into the field casting at the ends of the armature and will *increase* the resistance of the magnetic circuit by saturating it to a higher degree. No E. M. F. would be generated by the armature wire cutting *those lines*, since the same wire will cut them so that the E. M. F. generated at one end of the armature will be equal to, and of opposite sign to that generated at the other end. Thus the number of turns in the field coil of the type under discussion will be slightly *increased* by the direct magnetizing of the armature, and (using Mr. Lundell's statement of the comparative length of wire per turn) the watts necessarily spent in, and the cost of, the field coil must be at least 1.73 times that of the Thompson type. If the effect of the direct magnetizing of the armature were as great as Mr. Lundell claims, the increase in the watts spent in, and the cost of, the field coil, would be about two or three times that of the Thompson type, all other things being equal.

Mr. Lundell's opinion of the Thompson type does not seem to be shared by such eminent electricians and firms as Mr. Wood of The Fort Wayne Electric Company, Jenney Electric Motor Company, the United States Electric Lighting Company, and others, who have lately adopted the Thompson type.

I will further add that I did not *have to* abandon the type under discussion, but could have kept on building it, had I desired to, since the buyers of motors in general neither have the knowledge, time nor facilities for finding out if the type offered them is the best or not. The motor claimed by Mr. Lundell and built by me in 1888 was in public use and, so far as I know, is so yet. Proofs of my priority will be furnished, when needed.

OLOF DAHL.

NEW YORK CITY, Jan. 18, 1893.

COMPOUND WOUND MACHINES.—A LITTLE MORE LIGHT WANTED.

First I will thank Mr. J. F. Denison for his kind letter in THE ELECTRICAL ENGINEER, Vol. xv., No. 244, p. 20, and beg to say that my query in THE ELECTRICAL ENGINEER, xiv., No. 242, p. 606 was intended to elicit, not to shed, light on the subject, and, if possible, to draw into print information which, passed by the few, is yet of interest to all students of electrical engineering.

In practice a generator is needed which will maintain (*i. e.*, will not lower) its E. M. F. under load-increase from zero to that maximum for which the machine was designed. The exact *value* of this E. M. F., in volts, is fixed when the dynamo is built at, say, 110, 220 or 500. Besides this, it is also sometimes useful to have a machine in which we can change the *value* of the E. M. F. while still the machine will, by its compounding, maintain that E. M. F. constant whether the new particular value be made 110, 115 or 120 volts.

One way to change the E. M. F. value is to make the last few turns of the top layer of the shunt field circuit of German silver wire and to use a suitable contact to cut a number of these turns out of circuit when the E. M. F. is to be raised, say, from 110 to 115 volts. This was the method employed in isolated lighting Thomson-Houston incandescent dynamos, which were *also furnished with* the German silver flute as a series coil shunt. Other makers simply use a rheostat in series with the shunt field circuit.

The over compounded machine is designed to raise the *value* of the E. M. F. as the load increases up to a fixed maximum coincident with the maximum current which the armature can carry without dangerous heating.

If the maker places a shunt in his series coil *provided with* means of variation and issues a diagram of the various relative resistance values of this shunt, I may (*pace* Mr. Denison) have rightly assumed that he intended the said shunt to have some effect on the operation of the machine. That its removal was without any measurable effect on the working of the machine under any conditions, may show Mr. Denison that the machine was well designed although he certainly fails to show why, in this event, the variable shunt was placed on it.

In commercial manufacture a lot of machines built to the same specifications will on test perhaps compound well enough, but will have a variation in their respective E. M. F. values of 1¼ to 2 per cent. In some factories these are all corrected to give the one intended E. M. F. by means of adding to each a German silver or other resistance in shunt to the series coil; and these are what Mr. Denison calls "standard machines" as opposed to "variable shunt" (to series coil) machines.

It may be noted that in general, no machines are used without a rheostat in the shunt field circuit by which the E. M. F. is adjusted. This being so, it seems hardly necessary to use the series coil shunt to correct a variation that no ordinary consumer would be likely to think of, much less discover, without the aid of trained assistance.

Reference might be made to a possible slight alteration of compounding due to shifting the working range slightly along the characteristic through the use of the rheostat, but that question need not now be considered.

The question of the utility of the series coil shunt, whether fixed or variable, is still open to discussion. Shall it be regarded as a valuable commercial appendage to the generator or merely as an advertising refinement? Let us have more light.

J. STANFORD BROWN.

NEW YORK, Jan. 20, 1893.

TWO QUERIES.

I beg to be allowed to seek through the medium of your valuable journal information on the following points:

1. I have to separate several layers of thin iron sheets adhering to each other by the pressure of the air and which probably also "stick" together a trifle. There are eight sheets in each bundle. As it takes such a long time to separate them by means of a knife, I would like to know if some electromagnetic apparatus could not be devised to do this work quickly?

2. Can I make the varying pressure, between two discs constituting a microphone, visible by the aid of some electric device?

NEW YORK, Jan. 11, 1893. G. S. F.

THE USE OF ACCUMULATORS IN FRANCE.

I HAVE read with interest the various articles in your journal on the reason accumulators are not generally used in the United States, but I do not think any of the writers have touched on the real reason, viz., that all accumulators are sold here with the guarantee that during 10 years the cost of keeping them in order shall not exceed an average of 10 per cent. per annum ; so that the buyer can figure out in advance just what the item of repairs will come to. This figure of 10 per cent. per annum is for accumulators used for lighting, but even those used on the tramway are renewed by the accumulator company on a basis of so much per mile. The accumulator companies in the United States are very profuse in assertions as to the low cost of repairs and renewals, but show their want of faith by refusing to guarantee their assertions. I have recently visited the works of the Paris Company, which is running 25 storage battery cars, and found the cars running very satisfactorily from the point of view of the Tramway Company ; and the accumulator company which supplies and keeps in order the batteries states it is making money on the contract. Add to this that the public are very much in favor of this kind of traction, and it appears that everybody is pleased. N. W. BARTOL.

PARIS, FRANCE, Dec. 23, 1892.

FIXED CLOSED COILS IN ALTERNATING MOTORS.

THE number of *La Lumière Électrique* for Dec. 24, 1892, which has just reached us, contains an article by F. Gilbert on a method, attributed to MM. Hutin and Leblanc, of constructing alternating current motors and dynamos so as to improve their efficiency, output and regulation. The method consists in short in disposing about the armature fixed closed circuits. We desire to state that this arrangement is the subject of a patent application of ours now pending. As your readers may remember, we have already patented the use of fixed closed coils parallel to the magnetization of the field (U. S. patent, No. 479,675). The present arrangement consists in the combination of such coils with others transverse to the field magnetization. The combination of the two sets serves to neutralize the self-induction of the armature and to lessen the reaction on the field due to the varying reluctance and M. M. F. of the armature.

We do not wish in any way to question MM. Hutin and Leblanc's originality in this matter, although the most important part of the combination was described long ago by us. We are even prepared to read in the columns of their organ, conducted by the virtuous Dr. Cornelius Herz, that this is another signal instance of American copying of European work.

W. STANLEY, JR.
JOHN F. KELLY.

THE STANLEY LABORATORY COMPANY,
Pittsfield, Mass., U. S. A. Jan. 24, 1893.

PERSONAL.

HONORS TO NIKOLA TESLA.

DURING Mr. Nikola Tesla's sojourn abroad last year, a special deputation of prominent scientific men of Servia was sent to Budapest by the Servian Government to escort him to Belgrade, where the young King Alexander I., of Servia, granted him a special audience and evinced great interest in the work in which Mr. Tesla is engaged. In recognition of his merit, King Alexander has just created Mr. Tesla a Grand Officer of the Order of St. Sava. The insignia of the Order have just been transmitted to Mr. Tesla from Belgrade.

MR. E. CALDWELL, associate editor of *The Electrical World*, and during the last eighteen months in charge of the editorial department of that paper, has resigned his position, and will hereafter have no connection whatever with the concern. Mr. Caldwell writes us that he goes to Chicago to become editor of the *Street Railway Gazette*, in which, with some friends, he has secured a controling interest. He is an old electric railway man, a clever writer, a conscientious worker and one whom everybody will wish abundant success. We do, with all our heart.

MR. CHAS. P. BRUCH, formerly secretary of the T. M. B. A., later of the Empire City Electric Company, and more recently connected with the Postal Telegraph-Cable Company has now been appointed assistant secretary of that company, with his office at the headquarters, 1 Broadway. Mr. Bruch's steady rise is watched with much pleasure by a host of old friends.

ANOTHER SOUTH AMERICAN CABLE.

THE CENTRAL AND SOUTH AMERICAN TELEGRAPH COMPANY has authorized an increase of its capital from $6,500,000 to $8,000,000 for the purpose of duplicating its cable lines on the west coast of Central and South America. The new line is to go from Santa Cruz, Mexico, to Chorillos, Peru, and will be completed about May 1.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 17, 1893.

Accumulators:—

Secondary Battery, H. H. Lloyd, Philadelphia, Pa., 490,254. Filed Aug. 30, 1892.

Comprises a perforated conducting support having pieces of active material supported in the perforations; separators between the supports and a woven fabric disposed between the separators and the faces of the positive plate.

Alarms and Signals :—

Electric Alarm Lock, J. A. Nadeau, Detroit, Mich., 490,161. Filed Sept. 2, 1892.

Dynamos and Motors :—

Commutator Brush and Holder, J. F. McLaughlin, Philadelphia, Pa., 490,081. Filed Mar. 31, 1890.

Invention consists of one or more blocks of conducting material hinged to a shank which moves in the line of a radius of the commutator cylinder, against which the brush is yieldingly held.

Commutator Brush, C. O. Billberg, Philadelphia, Pa., 490,183. Filed Sept. 20, 1890.

Consists of copper or equivalent metal on the entering edge with a backing of carbon or similar material on the leaving edge.

Galvanic and Thermo-Electric Batteries:—

Electric Battery, J. H. Davis, Detroit, Mich., 489,938. Filed Mar. 28, 1892.

Claim 1 follows :

In a primary battery the combination of a carbon element, a zinc element, and an insulator interposed between the two constructed of soft rubber and having grooves in the periphery thereof.

Galvanic Battery, N. M. Powell, Galesburg, Ill., 490,231. Filed Dec. 19, 1891.

Has for its object to provide means for automatically supplying water to the cell when necessary.

Heating :—

Electric Heater, T. E. Morford, Minneapolis, Minn., 490,034. Filed Dec. 19, 1890.

Employs a heated surface plate and a coating of enamel in which the resistance is embedded, and by which it is insulated from the plate.

Electric Heater, J. F. McLaughlin, Philadelphia, Pa., 490,082. Filed Apr. 28, 1892.

Claim 1 follows :

An electric heater composed of a conductor of high electrical resistance embedded in a mass of fire proof material coated with glazing or enamel.

Electrically Heated Soldering Iron, G. R. Meitzler, Cincinnati, O., 490,256. Filed Mar. 31, 1892.

Miscellaneous :—

Electric Telemeter Transmitter, F. J. Dibble, 490,012, Peabody, Mass. Filed Nov. 21, 1891.

Has for its object to record not only the speed but the direction of movement of a rotating shaft.

Electric Telemeter Transmitter, F. J. Dibble, 490,013, Peabody, Mass. Filed Nov. 21, 1891.

A system which may be operated over a single line circuit employing a single line battery or generator.

Electric Telemeter System, F. J. Dibble, 409,014, Peabody, Mass. Filed May 12, 1892.

Similar in its object to 490,012.

Mechanism for Testing Watch Balances and Hair Springs, G. E. Hunter, Elgin, Ill., 490,202. Filed July 2, 1892.

Method of Testing Watch Balances and Hair Springs, G. E. Hunter, Elgin, Ill., 490,203. Filed July 2, 1892.

Automatic Releasing Device, H. P. Nielsen, Alameda Cal., 490,211. Filed Sept. 14, 1892.

A device for electrically releasing hitched animals, such as fire engine horses, etc.

Railways and Appliances :—

Electric Car Brake, A. C. Miller, Auburn, N. Y., 489,972. Filed Nov. 30, 1891.

Trolley, J. C. Love, Chicago, Ill., 490,028. Filed May 17, 1892.

Employs two trolleys and two independently yielding spring supported arms on which they are mounted, the arms being pivoted to the free end of the main arm.

Electric Railway System, T. Harris, Detroit, Mich., 490,248 Filed Dec. 28, 1891.

A system employing sectional underground conductors successively rendered active as the car passes over them.

Switches and Cut-Outs :—

Electric Railway Switch, A. C. Goetz, Milwaukee, Wis., 489,944. Filed Sept. 27, 1892.

A railway track having a branch track and a movable switch point; two sets of insulated sections of the rails on the same side of the switch point but at a greater and a less distance therefrom respectively, helices connected to a set of the insulated sections of the track and a device connected to the switch point adapted to be reciprocated by the energizing of one or the other of the helices, and by its reciprocation to shift the switch.

Electric Cut-Out, W. B Potter, Lynn, Mass., 489,983. Filed July 5, 1892.

A fuse box having a chamber with an opening through the wall of the box, a magnet adjacent to said chamber, and a safety fuse in the chamber between the magnet and the opening.

Electric Circuit Breaker, E. Thomson, Swampscott, Mass., 490,178. Filed Oct 28, 1892.

Claim 1 follows :

The combination of a multiple contact-circuit breaker with self inductive coils arranged to preserve a proper distribution of the current between the different paths provided for it. (See page 107 this issue).

Telephones and Apparatus :—

Telephone, C E. Scribner, Chicago, Ill., 489,990. Filed June 1, 1888.

Claim 1, follows :

A carbon telephone transmitter disc electrode provided with inclined concentric rings forming deflecting surfaces.

Electric Meter, F. J. Dibble, Peabody, Mass, 490,011. Filed Nov. 21, 1891.

Has for its object to provide means whereby irregular movements of the contact arm shall be made to transmit a regular and uniform movement to the indicating device.

Telegraphy and Telephony, F. H. Brown, Chicago, Ill., 490,064. Filed Feb. 27, 1891.

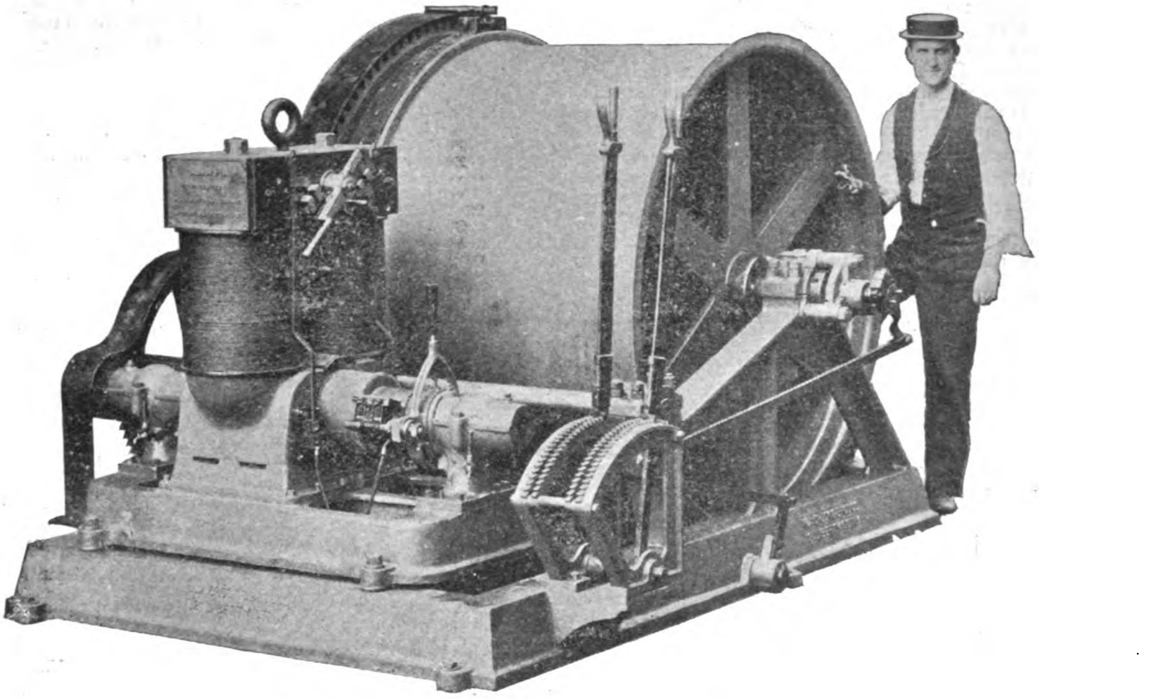
An instrument which may be used either as a telegraph or a telephone and will operate as a telephone on a telegraph circuit.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

NEW GENERAL ELECTRIC MINING HOIST.

A NEW electrical mining hoist has been recently brought out by the General Electric Company. It is constructed with the especial object of obtaining a wide range of hoisting speed, to which end the controlling apparatus has been carefully perfected. The drum is of unusually large diameter and is connected by an intermediate gear to the armature shaft of a 25 kilo watt, (30 h. p.) motor of the General Electric Company's regular bi-polar type. The controller for the motor is similar to that used in street railway service, and is erected on a separate support conveniently within reach of the operator and directly to the right of the levers. These can then be operated with the left hand, and the controlling switch with the right. The series method of electrical control is adopted, the speed being increased or decreased to meet requirements, by the movement of the switch handle. The hand brake is of the band type, lined with wood, and extends almost entirely round the drum. The drum is thrown into operation by a clutch operated by the second lever.



New General Electric Mining Hoist.

The range of speed obtained on this hoist is very wide. It is designed to raise loads of 1,300 lbs. at a rate of 600 feet a minute, and has successfully accomplished this. It can also raise loads of 100 lbs. at a speed not exceeding 20 to 30 feet a minute. The motor is erected on its own bed-plate bolted to the bed-plate of the hoist proper, the whole apparatus occupying comparatively little space owing to its compact construction.

"THE MINERAL INDUSTRY."

"THE Mineral Industry, Its Statistics, Technology and Trade in the United States and Other Countries, From the Earliest Times to the Close of 1892," is the annual statistical supplement of the *Engineering and Mining Journal.*

The great work of collecting and publishing in the *Engineering and Mining Journal*, within a few days of the close of each year, reliable statistics of the mineral industry of the United States and other countries, whose products are valued at far more than $2,000,000,000, has become so important that a large octavo volume will be issued shortly covering them, and will be, it is said, the most complete and valuable report of mineral statistics ever published.

It will treat each of the various subjects in the following general order: Describing the occurrence and character of deposits in which the minerals are found; the characteristics of the mineral methods of treatment; cost of mining; characteristics of metal or other products; costs; uses; statistics of production; imports and exports from the earliest times; consumption, total and per capita; review of markets; prices; foreign production; imports, export and consumption; extremely valuable technical articles by the most competent authorities, giving the recent progress in each department of mining and metallurgy. Diagrams will illustrate each important feature of this industry. The tables of itemized cost of production of many of the minerals and metals will afford information of the utmost value. The progress in the chemical industry will be given in expert reports covering the industry to the close of the present year in Europe and America.

THE STERN INCANDESCENT LAMP.

IT is reported that a big factory is to be started at Buffalo, N. Y., to manufacture the incandescent lamp invented by Mr. Philip K. Stern, of that city, and that the initial capacity is to be 25,000 lamps a day. The factory is to cost $250,000. "In the Stern electric lamp the filament is embedded in solid glass. The loop is of pure and solid glass, and in the middle of the glass is the filament firmly embedded. There is therefore no loss of substance, for though the carbon particles may vibrate, yet no particle can be lost. There it is in the glass. There it must stay, and no matter how long the electric current vibrates through it, it will retain its substance and pour forth light. There is no vacuum in the lamp. Air will be rather pumped in than out, to prevent the expansion of the glass when it is heated. Air will be used to prevent expansion of the glass and thus there is no confliction with Edison's patents in the matter of a vacuum. Stern's lamp is unique. It is a marvelous light giver and when once put up it is there to stay. It will not burst like ordinary electric lamps when struck and throw fragments of glass in one's face."

WILSON & JACKSON.

THIS firm has been formed by C. H. Wilson and George W. Jackson, with headquarters in the Times Building, Chicago. Mr. Wilson is well-known from his long and active connection with the telephone system in Chicago. The firm will devote itself to the construction of underground and aerial plants for electrical companies.

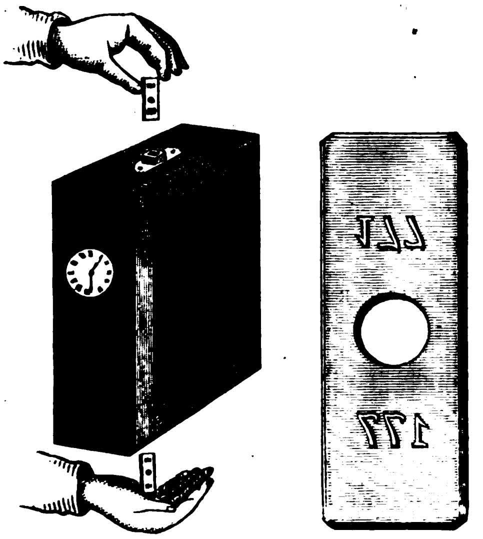
NEW YORK NOTES.

MESSRS. W. S. CHESLEY & CO. who have recently opened a well equipped repair shop at 24 Morris street, Jersey City, are also doing an extensive business in buying and selling all kinds of electric light and power apparatus. Although they deal largely in second-hand material, they believe in using nothing but the newest and the latest designs of machinery in their factory. Mr. Chesley has had a long experience in electrical work, and deserves support.

ENGLISH'S WORKMAN'S TIME RECORDER.

THE accompanying illustrations show an ingenious automatic time recorder, invented by Mr. J. C. English and introduced by the Columbian Time Recorder Company, of 82 Frankfort street, New York City.

The mechanism is inclosed in a polished oak case, 17 inches high, 14½ wide and 7 deep, shown in Fig. 1, in the top of which is a slot for the reception of checks carried by the workmen and having raised numbers by which the men are known. Fig. 2 shows one of these checks full size. The employé in passing the recorder drops his check into the slot at the top of the box and receives it in the other hand from the bottom. Checks can be recorded in this manner, one workman following another in succession, at the rate of 50 or more a minute, or they can be passed through the recorder by a single individual at the rate of 125 a minute, the machine recording each check in a perfect manner. The results of the recording are shown in Fig. 3, which is a reproduction of a portion of the printed record, as made by six workmen passing their checks through the machine. It will be seen that these men passed the recorder between five and eight minutes past 6 o'clock.



TIME H.	TIME M.	WORKMEN'S NOS.
6	6 5	22
6	6 5	32
6	7 6	14
6	7 6	40
6	8 7	12
6	8 7	19

FIGS. 1, 2 AND 3.—ENGLISH'S WORKMAN'S TIME RECORDER.

The interior construction of the recorder consists of a train of gears, operating a hammer; a stop for the check, hour and minute wheels operated by an eight-day double-spring Seth Thomas movement; an inked ribbon and a reel for carrying the roll of recording paper. The check upon entering the slot is guided in its course downward by runways until it strikes an arm, which stops the check, holding it until it is recorded by a blow from the hammer, and at the same time closes the slot, so that but one check can be put into the slot at a time. The blow from the hammer releases the check, allowing it to drop out of the case, and also opens the slot for the reception of another check. The various operations which are gone through during the passage of the check from the time it enters until it leaves the case are very simple, and only occupy a second of time or less.

RAILWAY EQUIPMENT COMPANY.

THE annual meeting of the stockholders of the Railway Equipment Company, Chicago, was held on Tuesday, 17 ult., and the report of General Manager W. R. Mason showed a most satisfactory state of affairs. The business of the company has been very greatly in excess of expectations and is daily increasing. The late devices brought out by the company have had an unprecedented sale and are being adopted throughout the entire country. Mr. Mason called attention to the need of further increasing the manufacturing facilities. We understand that a very prominent capitalist has become interested in the company with the intention of still further increasing its business.

ANNUAL REPORT OF THE NEW YORK EDISON COMPANY.

The annual meeting of the Edison Electric Illuminating Company last week resulted in the re-election of the old board of directors. The report shows gross earnings, $942.575; expenses, $385,494; net, $557,080; income from other sources. $20,446; net income, $577,527; other expenses and taxes, $102,889; balance for interest and dividends, $375,187.

In 1889 net earnings were $124,031, against $435,177 in 1892. The number of customers has increased from 1,218 in 1889 to 4,344 in 1892; net earnings increased 86 per cent. in 1892 over 1891.

The financial plan provides for the increase of the capital stock to $6,500,000 and of the first mortgage bonds to $3.250,000. The Manhattan Company and the Harlem Lighting Company have been brought into harmonious relations with the Edison Company, through the Edison Light and Power Installation Company. The work of the company in 1893 will be much less costly than it has been during the three previous years.

NEW ENGLAND NOTES

COLONEL R. C. EDEN, who has for some time past been assistant manager of the Brookline Gas Company, was presented a few days ago, on the occasion of his resignation, as a token of their appreciation of his efforts, by a number of his fellow employees, with a handsome gold-headed cane with inscription, a silver mounted umbrella, silver mounted pipe, a box of cigars and a few other articles calculated to cheer him on his release from his arduous duties. Col. Eden has become well known to a large number of electrical men in the vicinity of Boston, and has endeared himself to many by his straightforward and manly qualities., and thorough practical knowledge of his work, and the Brookline Gas Company lose the services of one whose position it will be difficult to fill, and one who was always ready to undertake the hardest duties for the interests of the company he was working for. He has the heartfelt good wishes of a large number of warm friends, who wish him well in his new field of labors.

THE EASTERN ELECTRIC CABLE COMPANY, of Boston, have recently declared another of their regular semi-annual dividends of 8 per cent. on the preferred stock. Mr. Henry A. Clark, the treasurer of the company, reports that the business for December of the past year, was 50 per. cent. in excess of what it was for the same month in the preceding year, and that he is constantly making additions to his factory to accommodate their rapidly-increasing business. The Clark wire grows more popular year by year, owing to its unvarying uniformity and excellent insulating qualities. The Eastern Electric Company have now one of the largest and best equipped factories in the East for the manufacture of high grade wires and cables, and they are now making large additions and installing some very heavy machinery for the manufacture of the very heaviest types of telegraph, telephone and electric light and railway cables.

THE MASSACHUSETTS ELECTRICAL ENGINEERING COMPANY, of Boston, have recently closed a contract by which they will design and have charge of the construction of a model central lighting station at Oconomowoc, Wis., with a capacity of about 3,000 incandescent lights and 80 arc lights. The station will be situated in the residence portion of the city, and will be built of Milwaukee brick, and everything done to make it handsome and in keeping with its surroundings. The Massachusetts Company have also charge of the new station of the Rumford Falls Light and Water Company at Rumford Falls, Me. The station will be built for incandescent and arc lighting, and power circuits, and will also probably be heated by electricity. It will be operated by turbines, the surplus power being used for heat.

SWAN AND LANE, of Boston, have just completed the wiring of the Taunton Opera House, at Taunton, Mass., where they have installed about 700 incandescent lights. They have installed a very simple and effective switchboard and stage regulators and have introduced a number of original ideas in the way of controlling the lights and producing novel stage effects. They have a large quantity of other work on hand, most of it being done without any contract prices, but simply on a cost basis, so that the best of electrical work can be put in, without regard to keen competition prices.

THE BERLIN IRON BRIDGE CO., of East Berlin, Conn., have received the contract for rebuilding the Tube Mill of Curtis & Co., at Cohoes, N. Y., lately destroyed by fire. The new plant will be fire-proof, constructed entirely of iron and brick, no wood-work being used. The building will be 132 feet wide by 131 feet long, with a wing on one side 20 feet wide by 74 feet long.

THE NEW ENGLAND ENGINEERING COMPANY, of 180 Summer street, Boston. will be the new name of the Electric Railway Engineering Company, as it has been recently re-organized. Mr. J. F. McGowan will continue as manager, and Mr. A. W. Jaastad as chief engineer.

THE BROCKTON STREET RAILWAY COMPANY of Brockton, Mass., have ordered a new 500 h. p. Erie Ball cross-compound engine, and multipolar generators of a similar capacity.

"RIGHT UP TO DATE."

A PHILADELPHIA reader writes us: "Being interested in this science only in my desire to know 'what is going on,' I hav found the ENGINEER to be a first-class medium for keeping me posted 'right up to date.'"

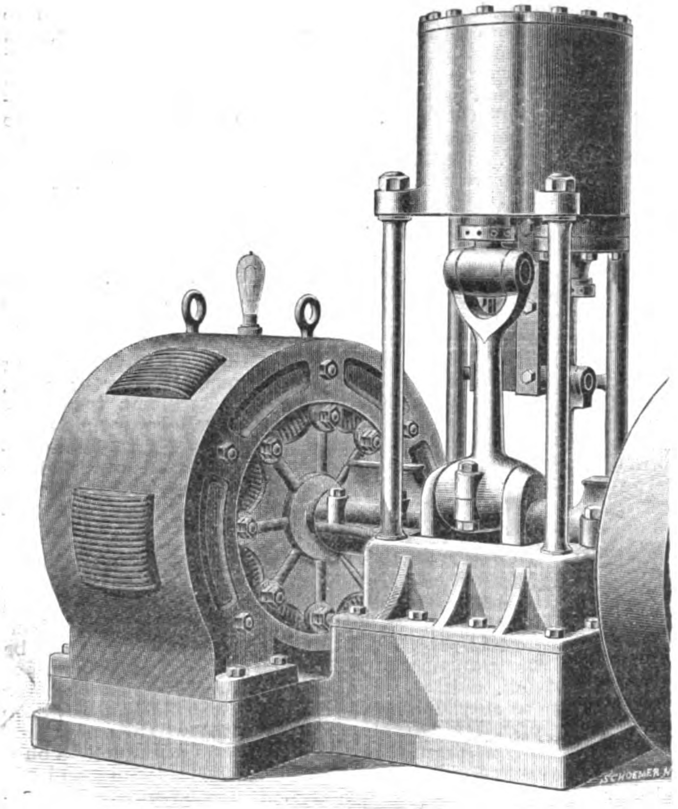
THE RIKER MULTIPOLAR MARINE DYNAMO AND ENGINE.

The accompanying illustration shows a direct connected engine and dynamo designed especially for yachts by the Riker Electric Motor Co., of 45 and 47 York street, Brooklyn.

For 100 lights and upward, the armature is attached directly to the engine shaft. The engines are light and the dynamos are of low speed. The combination is a marvel of compactness and lightness, showing very high efficiency, weight, speed and dimensions being considered.

These plants are designed for a minimum steam pressure of 80 pounds. The largest, built for 225 lights, occupies a deck space of only 10 square feet—5 x 2—has an extreme height of 56 inches, and weighs 1,525 pounds.

The catalogue for 1893, issued by the company, is a very attractive little pamphlet, illustrating and describing a quantity of interesting Riker apparatus, and containing, beside, some excellent half tone reproductions of yachts that are well worth framing.



SCHOENER N.Y.

Riker Multipolar Marine Dynamo and Engine.

A NEW FACTORY FOR THE AMERICAN ELECTRICAL WORKS

The American Electrical Works have recently purchased from Charles Fletcher, the Richmond Paper Co.'s Mills in East Providence. This property originally cost the Paper Co. $1,000,000, and was sold January 11, at auction, to Mr. Charles Fletcher for $42,000. The American Electrical Works paid something of an advance on this, but consider they have acquired a large amount of mill property at a remarkably low price.

The plant consists of about 28 acres of land, three miles from the city of Providence, upon the Seekonk River, and upon the Providence & Worcester R. R., affording excellent water and railroad communication.

The buildings are mainly of brick, and of the following dimensions: One building 160 x 65, four stories; one building 200 x 50, one story with attic; two buildings 150 x 60, one story; one building 200 x 30, one story; one building 200 x 40, one story; one building 130 x 60, one story.

The one story buildings are constructed with walls suitable for an additional story. There are also an engine house, boiler house, water filter beds and a large boarding house and several tenements.

The steam plant consists of two Greene improved engines of 600 h. p. each, and 14 six feet horizontal tubular boilers, in good order. The water supply is abundant, and of the purest quality. The plant will be used for the extension of the business of the American Electrical Works.

WESTERN NOTES.

The Electric Appliance Company are just receiving the first large shipment of their new lamp sockets to be known as the Acme. While the socket has no peculiarly startling features, it has a number of small improvements over others in the market in small details, such as an increased amount of room for the wiring cord; extra long contact screws for securing the cord; and a heavy and handsome shell. In fact it is a splendidly made socket in every way. The Electric Appliance Company are putting in a very large stock in anticipation of heavy demand which will no doubt be realized.

Mr. S. W. Hume, so well known to the engine and machinery trades through his long connection with *Power*, has decided to become a resident of the World's Fair City, and will hereafter represent as Western Manager, *Power*, and the new journal, *Heating and Ventilation*.

A Neat Order.—George Cutter reports an order from the Chicago City Railway Co. for 14 miles of Simplex waterproof wire of 500,000 circular mils. This is made with 76 strands of Number 12 wire, over 1,000 miles of this size being needed for the purpose.

Mr. G. W. Russell, of Russell & Officer, Denver, Col., was in Chicago last week and reports a large demand for their automatic switch.

NEW YORK NOTES.

Frank R. Chinnock, 18 Cortlandt street, New York, Eastern agent of the Ball Engine Company, of Erie, Pa., reports large sales of this well-known engine throughout his territory. The following are among the recent orders he has filled: Buffalo, North Main and Tonawanda Street Railway Company, Tonawanda, N. Y.; Ithaca Street Railway Company, Ithaca, N. Y.; Seabury & Johnson, East Orange, N. J.; Hahne & Co., Newark, N. J.; Dow's Stores, Brooklyn, N. Y. The Ball Engine Company recently issued a handsome descriptive catalogue, and Mr. Chinnock would be glad to furnish it to any one desiring information on automatic high-speed engines for electrical purposes.

The Goubert Manufacturing Company, located at 32 Cortlandt street, New York City, makers of the Goubert Feed-Water Heater, have purchased the patents, stock and business of the Stratton Separator Company, and are now the sole manufacturers of the well-known Stratton Separator. This device for extracting entrained water and grease from steam, that it may be furnished dry to engine, is one of the most popular inventions of the kind on the market, and its manufacturers have enjoyed a substantial increase of business yearly.

The Crocker-Wheeler Electric Company, New York, are at work upon a new catalogue, which they will shortly issue for gratuitous distribution. The work will be finely illustrated and replete with information regarding the company's well-known and extensive line of dynamos, direct-current transformers, fan motors, etc.

Mr. H. W. Weller, of the New York Office of the Railway Department of the General Electric Company, has been in charge of their Railway Supply House, 24 West street, in New York, since Dec. 1st last. Since he has had this department under his care, the results obtained have been more than satisfactory.

The Shaver Corporation. Mr. G. F. Shaver, president of the above corporation, of No. 1 Broadway, which controls the Shaver and other telephone patents, reports, in reply to inquiries, that the company has a registered capital of $2,000,000 in $100 shares, now quoted at $75.

BALTIMORE NOTES.

The Automatic Switch Company have changed offices from No. 8 Keyser Building, to 703 and 705 Equitable Building, Baltimore city. The Equitable Building has just been completed and is one of the finest office buildings in this country. They will be happy to see their friends in these new offices.

THE
Electrical Engineer.

Vol. XV. FEBRUARY 8, 1893. No. 249.

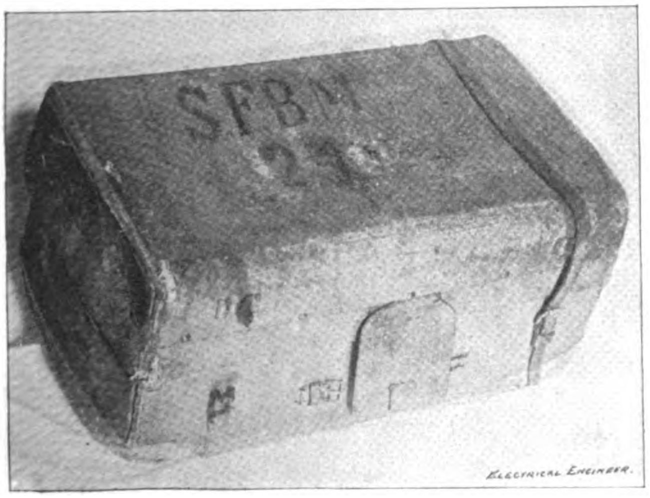
WILLIAM WALLACE, AND HIS CONTRIBUTIONS TO THE ELECTRICAL INDUSTRIES.[1]—II.

BY

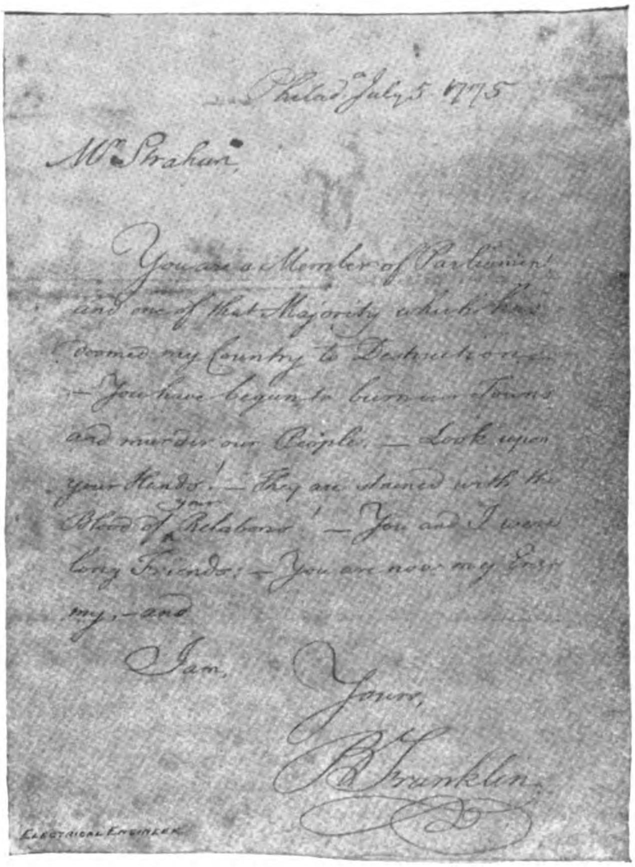
Wm. J. Hammer

IV.

MR. WALLACE was one of the little band of scientific men who assembled on that memorable Sunday afternoon in July, 1876, at the Centennial Exhibition at Philadelphia, to witness the first public exhibition of the Bell telephone. At that time Prof. Barker, representing the Exhibition authorities, was wont to gather together a coterie of men eminent in science and the industrial arts to witness private exhibitions of new inventions and objects of especial interest, and he was approached by Lord Kelvin, then Sir William Thomson, in behalf of a Mr. A. G. Bell, who, he said, wished to show his speaking telephone. To ensure quiet, Sunday afternoon was selected. The day was exceedingly warm and after repeated failures the crowd had grown very restless and impatient and Sir William came to Prof. Barker several times saying, "This is sheer nonsense." Presently, says Mr. Wallace, Sir William went to the other end of the line, and Mr. Bell, who had been nervously working over his apparatus, requested Dom Pedro, the Emperor of Brazil, who was among the party, to take the telephone and listen. "Do you hear anything, your excellency?" he enquired. "Yes," the white haired old savant tremblingly replied, beads of perspiration standing out upon his brow, and his eyes gleaming with nervous excitement: "I hear, 'To be or not to be, that is the question.'" This message, sent over the line by Sir William Thomson, was the first public message sent by telephone, and the scene, Mr. Wallace says, left an indelible impression upon his mind and on that of all others who were gathered there.



Prof. Morse's Trunk.



Philada July 5 1775

Mr Strahan,

You are a Member of Parliament,
and one of that Majority which has
doomed my Country to Destruction.
— You have begun to burn our Towns
and murder our People. — Look upon
your Hands! — They are stained with the
Blood of your Relations! — You and I were
long Friends: — You are now my Ene-
my, — and

I am,
Yours,
B Franklin

ELECTRICAL ENGINEER.

Franklin's Letter.

On September 15, 1849, Mr. Wallace was married to Miss Sarah Mills, of Birmingham, Conn., daughter of Thomas Mills. Mrs. Wallace has for many years past been a great sufferer and much confined to the house, and during Mr. Wallace's absence in Egypt a year ago, he received a cable announcing his wife's death. She left a son and daughter, William O. Wallace and Eloise E. Wallace, the former being married and living in Ansonia with his family, and acting as general superintendent of the works of Wallace & Sons. His daughter Eloise has for many years presided most ably over her father's household and assumed the care of her invalid mother. She is a woman of high intellectual attainments, an accomplished musician, and has traveled very extensively. The writer has been surprised to find in a woman such an amount of knowledge of electrical and mechanical matters. This is a taste that she has partially inherited, and further developed by her association with her father's work, into which she has entered with enthusiasm.

---

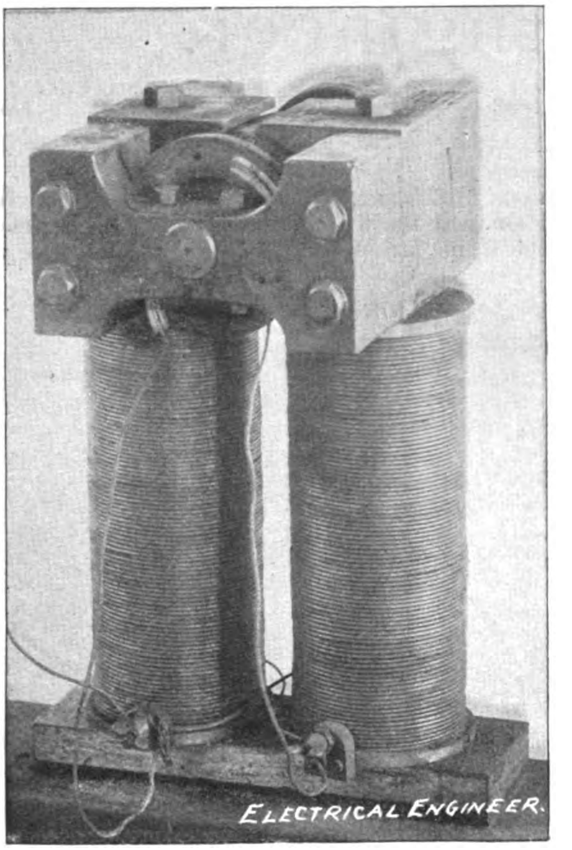
V.

Although Mr. Wallace has always been exceedingly modest in his claims as a pioneer in the electrical field, he has always manifested the greatest interest in the work done by others in this and other departments of scientific research, and has been ever anxious to champion the cause of the early workers. He has ever had a penchant for collecting souvenirs of great scientific and historical interest, and his laboratory is filled with many such, gathered both in this country and abroad. On page 129 is shown an old trunk, once the property of Prof. Samuel F. B. Morse, with which he traveled about this country and Europe, and in which he carried many of his valuable papers and apparatus. His initials may be seen upon the top of the lid, and pasted in various parts of the trunk are labels indicating visits to various parts of Europe.



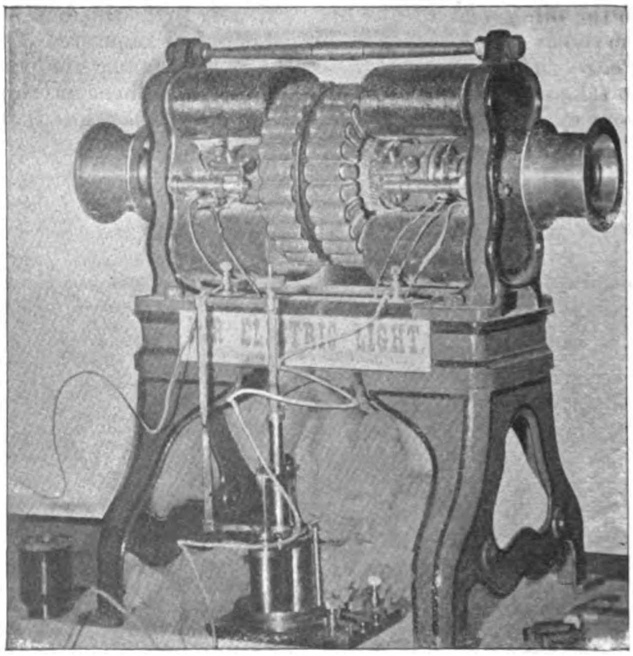
Wallace's First Dynamo of 1874.

Hanging up in the laboratory is shown a letter written by Benjamin Franklin to Mr. Strahan, a member of Parliament. This is also illustrated. It is considered one of the most interesting letters that Franklin ever wrote, and is now published in *fac-simile* for the first time. The illustration of Mr. Wallace's laboratory, shown last week, very inadequately represents the wonderful store of interesting things which the room contains, and it would be of great value to the Electrical Department of the World's Fair if they were to secure many of these valued relics for exhibition at Chicago during this year. The picture shows Mr. Wallace's large telescope, a number of his fine microscopes, his big Holtz machine, Crookes' apparatus, his magic lantern, and many other things of interest, and the cabinets and drawers about the room are filled with a marvelous collection of apparatus for experiments in electricity and magnetism, polarized light, sound and other departments of physics. The collection of lenses alone represents a not inconsiderable fortune. Upon the walls may be seen some of Prof. Draper's celebrated photographs of the moon, presented by him to Mr. Wallace, while here and there hang portraits of Faraday, Joseph Henry, Dr. Draper, and other well-known scientific men.

Besides being one of the largest manufacturers of copper and brass goods, Mr. Wallace has large interests in copper and gold mines in the West, as well as in iron mines in Virginia. At the time that laws were passed forbidding the mining of gold by hydraulic methods, at one time so extensively in vogue in the West, Mr. Wallace had considerable capital invested in this class of gold mining, which he says would have proved exceedingly remunerative but for the prohibitory laws which were passed because of the injury done to the scenery, the choking up of the streams, destruction of farming and grazing lands, etc., by the system of hydraulic mining employed. Besides these outside interests, Mr. Wallace has invested largely in stocks of important electric lighting and power enterprises. He believes in electricity.

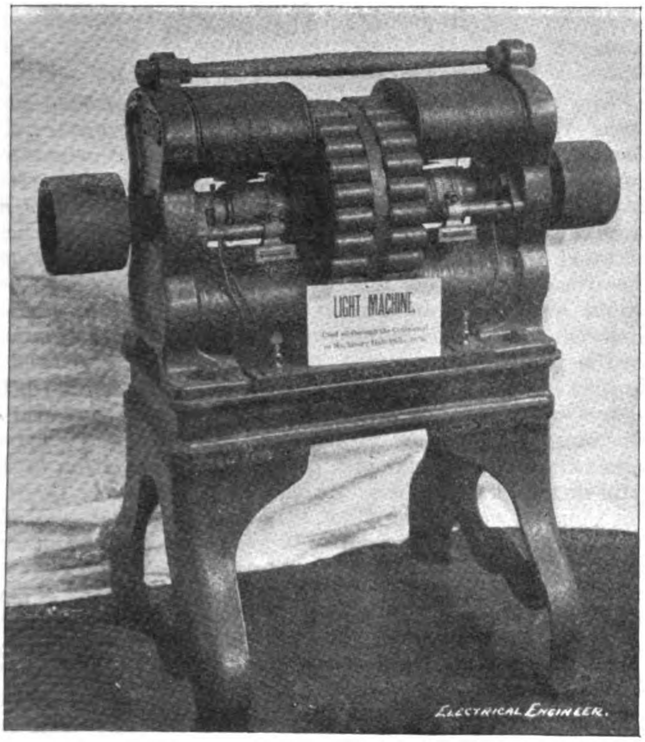
VI.

Mr. Wallace's work in dynamo electric machinery forms an exceedingly interesting chapter in this department of electrical development. He was the first builder of dynamos in this country, and the first manufacturer in America to apply the dynamo to the industrial art of electro-plating. Perhaps the readers of The Electrical Engineer may remember the great interest manifested in the fine display made by Mr. Wallace of his experimental types of dynamos and other historical apparatus which he exhibited at the Franklin Institute Electrical Exhibition in 1884. On this page is shown the first dynamo built in this country. It will be noticed that it consists of a simple horseshoe magnet inverted, between the poles of which revolves an armature of the Gramme type, the ring being quite broad. The brushes were attached to a rocker arm operated originally by a worm and gear, but not observable in the sketch here shown. This dynamo bears a marked resemblance to the Edison dynamo inverted, and resembles even more the recent standard types of dynamos of Siemens & Halske, of Kapp and others, made abroad, and of the Thomson-Houston incandescent type in this country. Having been constructed in February, 1874, it antedates all these, which, however, all employ the Siemens type of

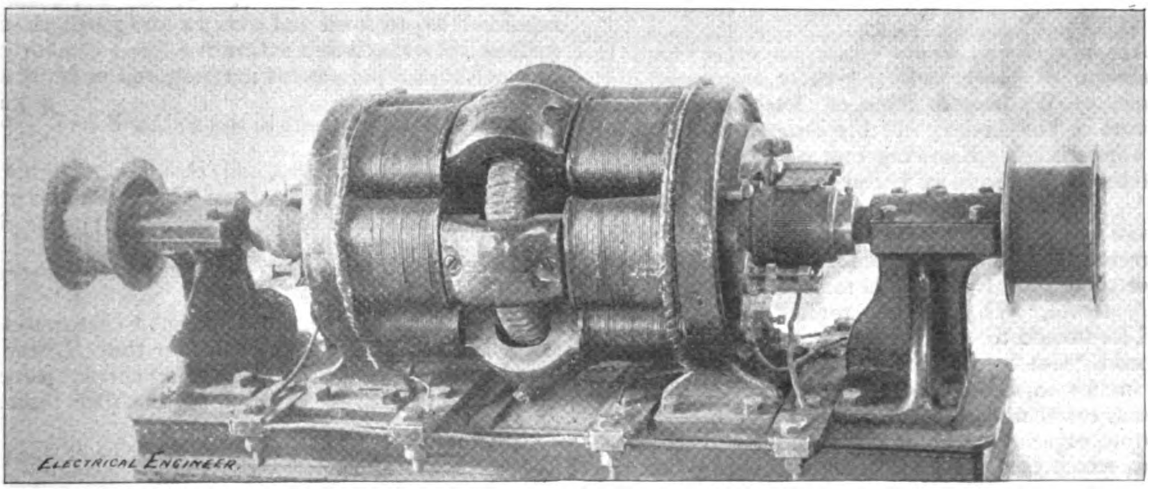


The Wallace-Farmer Dynamo.

armature. Considering historically this form of field magnet, it must not be forgotten that H. Wilde, of Manchester, brought before the Royal Society, April 26, 1866, a description of a dynamo having a field of the "horseshoe" form, the magnet being, however, very broad and flat, an armature of the Siemens shuttle-wound type, and the field separately excited by a magneto-machine.



THE CENTENNIAL ARC LIGHT DYNAMO, "WALLACE-FARMER."



THE "TELEMACHON."

Mr. Ladd later made a dynamo with upright fields broad and flat and of the same general construction as Wilde's. Still earlier, Pixii, E. M. Clark, Stöhrer, Gramme and C. W. Siemens constructed hand magneto-machines with upright "horseshoe" magnets of steel. The construction of the dynamo shown here was undertaken by Mr. Wallace after hearing from his intimate friend, Prof. Geo. F. Barker, of the University of Pennsylvania, of the wonderful Gramme dynamos he had seen in the Vienna Exposition of 1872, and in use also in London, that same year, at which time Werdermann, who represented Gramme in England, was making his experiments in lighting the tower clock of the Houses of Parliament by means of the Serrin arc lamp and Gramme dynamo. Mr. Wallace shortly thereafter built a number of other types of dynamos which I shall refer to later on, employing armatures of the Siemens, Gramme, Pacinotti, drum, and multipolar types, and his firm secured the services and co-operation of the well-known electrician, Prof. Moses G. Farmer, at that time residing in Boston. Prof. Farmer was contemporaneous with Werner Siemens in his discovery that the current generated by the armature could be utilized for the energizing of the field magnets, rendering separate excitation of the field by magneto-machines unnecessary.

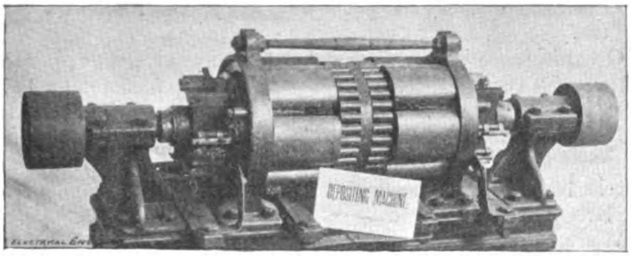
Farmer took out a patent in 1872, covering the combination in one circuit of the armature, field, line wire and work done. He built a dynamo with multiple-poled field and armature, which was considerably improved by Mr. Wallace, who gave it the permanent form as shown on page 130. The magnetic field was produced by two horseshoe electromagnets with opposite poles facing each other between the arms of the magnets, and passing through the uprights supporting the magnets is the shaft carrying the rotating armature. This consists of a disc of cast iron near the periphery of which are 50 wedge-shaped iron cores wound with wire, 25 being set at right angles to each face of the disc, thus forming a double series of coils. It will be noted that this is really a double machine, each set of coils having its commutator and being capable of being used independently. In practice the electrical connections were so made that the currents generated in two series of armature coils pass through the field coils and are joined in one external circuit.

On this page is illustrated the Wallace-Farmer dynamo which was run all during the Centennial Exposition of 1876, where it supplied the first electric lights started up and the only one used for illuminating the Exposition buildings and grounds. In addition to this, the Gramme dynamo and Serrin lamp were shown as an exhibit in the French section by Breguet.

Wallace & Sons began the manufacture of this type of machine for the market early in 1875, constructing it especially for arc lighting in conjunction with the Wallace "Plate Carbon" arc lamp, continuing however extensive experiments in dynamo construction.

The most interesting machine resulting therefrom is also shown on this page, termed by Mr. Wallace, the "Telemachon" and described as being for the development of power at a distance from its source. It was constructed in November, 1875, and was exhibited at the Centennial Exhibition at Philadelphia, in 1876. A record in the shop states that this dynamo at a speed of 1,000 revolutions supplied eleven arc lamps when driven by an inch and a quarter belt, the pulleys being eight inches in diameter. This machine contained a Gramme ring armature, and the most interesting fact connected with it is that it is the first armature in which laminated plates of iron were used. Mr. Wallace says: "In those days we knew nothing of hysteresis, eddy-currents, or Foucault-currents, but I was aware that there was a loss caused by what I termed interference of magnetism, and made the core of iron plates twelve in number separated by shellaced paper to obviate this difficulty. My experiments in building induction coils suggested my breaking up or laminating the iron core." Mr. Wallace says he believes this machine has to-day no superior in the market. As with the Wallace-Farmer dynamo, the armature possesses two sets of coils and two commutators and a driving pulley at each end of the shaft, it being considered as an advantage in driving, and by use of two driving belts lessening the risks, saving wear upon bearings, etc. Many experiments were made with this machine in running the circuits separately, in series, and in multiple for various purposes, though I believe it never occurred to anyone to try it as a motor transformer, which, one would think, would naturally have suggested itself.

This is the machine which Mr. Frank J. Sprague referred to at the Providence Convention of the Nat'l Elec. Lt. Assn. in 1891. An extract from Mr. Sprague's remarks are worthy of reproduction here: "Well, by some good intervention, I was ordered back to the United States, and I went to Ansonia, Conn., where I saw an experiment in the transmission of power which greatly impressed me. Mr. Wallace, of Wallace & Sons, of Ansonia, is a man whose position in the history of this enterprise has never been fully appreciated. Knowing him personally, he took me through his factory, and said 'Sprague, let me show you something.' He had one of those old two-pole armature machines, and had connected it with a dynamo. He turned on the current, and pretty soon the armature was running two or three thousand revolutions a minute. He said, 'It is no good.' I said, 'Why?' He replied, 'I will show you.' And he turned to one of the men—a large strong man—and said, 'Get hold of the pulley.' The pulley was about ten inches in diameter. The man threw his arms around it and, lowering its speed, finally brought it to rest. In that simple experiment he outlined, and he overlooked, the most important fact that he had to deal with—that the work done was not determined by the torsional effort alone, but that this should be multiplied by the speed at which the pulley rim was travelling. Had Mr. Wallace seized on that single point, or had I, at that time, the transmission of power would then have been very much advanced."



THE CENTENNIAL PLATING MACHINE, "WALLACE-FARMER."

The cut on this page represents a special type of Wallace dynamo for electro-plating purposes. This machine was shown at the Centennial Exhibition at Philadelphia in 1876, and built first in the year previous. This machine was capable of heating to a white heat 18 feet of number 8 B. and S. gauge copper wire. Wallace & Sons still manufacture plating machines, though confining their attention to the well-known "Little Joker" plater. This is the only type of dynamo now manufactured by them.

THEORETICAL ELEMENTS OF ELECTRO-DYNAMIC MACHINERY.—XV.

BY

A. E. Kennelly

STRESS DISTRIBUTIONS (CONTINUED).

Now suppose the polar surfaces reduced to 1.5 sq. cms. each. With the same total flux through the armature, the density at the contact surfaces will be 13,333, representing a stress of 7.3 kilogrammes per sq. cm., or a total stress at each pole of 10.95, and for both poles combined 21.9, an increase of 5.68 above the preceding case. We have here assumed that the total flux of 20,000 lines passed through the armature was the same in each case, but in reality there would be some reduction in the flux as the polar surface diminished, and this reduction would become more marked as the polar area reduced, so that finally when the flux density in the soft iron at the polar areas approached 18,000 C. G. S. lines per sq. cm., or in other words, as the iron at those areas approached saturation, the advantage gained by increasing B would be just offset by the reduction in the total flux that would pass through the surfaces. Beyond this point of maximum effect, still further reduction of the polar contact areas would result in a lessened total attractive force. This maximum would depend upon all the conditions of the magnetic circuit, and its determination may be left for later consideration.

These principles also explain the advantage that is secured for permanent magnets of hard steel by softening their poles when these latter are of due proportions. Hard steel is necessary for their construction in order that the countermagnetic flux from their poles may not demagnetize them, but at the polar surfaces, it is desirable to have B^2, and therefore B, as great as possible for a large tractive power, and soft steel will more readily permit a high intensity to be obtained.

Similarly they indicate the necessity for employing a permanent magnet in a receiving Bell telephone in place of a soft iron core. Assuming that the diaphragm of ferrotype plate is so close to the pole, that the flux density may be regarded as uniform and everywhere perpendicular to the surfaces, the maximum attractive force due to a soft iron core without a permanent magnet, and under the influence of an alternating current in the coil, will be $\frac{A\,B_c^2}{8\,\pi}$, where A is the effective polar area, and B_c is the maximum intensity that the alternating current can effect. The insertion of the bar magnet produces a steady normal pull on the diaphragm of $\frac{A\,B_m^2}{8\,\pi}$ dynes, where B_m is the permanent magnetic intensity. If this is not nearly sufficient to saturate the iron at the polar surfaces, we may consider that B_c may be superposed upon B_m when the alternating current passes through the coil. The stress exerted on the disc then alternates between $\frac{A}{8\,\pi}(B_m + B_c)^2$ and $\frac{A}{8\,\pi}(B_m - B_c)^2$, a total range of $\frac{4\,A\,B_m\,B_c}{8\,\pi}$ which is generally much greater than the original value $\frac{A\,B_c^2}{8\,\pi}$ and the electromagnetic effect of the coil becomes correspondingly augmented in the ratio of $4\,B_m$ to B.

Experiment shows that the friction to sliding between two smooth or nearly smooth surfaces of iron under magnetic stress, is not sensibly different from that accompanying the same stress exerted mechanically, so that if f is the coefficient of friction (sensibly 0.2) between ungreased

---

1. Copyright 1892, by A. E. Kennelly.

smooth surfaces of iron, the stress that it will be necessary to apply between them parallel to the plane of contact will be $\frac{f}{8\pi}\int B^2\,ds$, or about one-fifth of the total tractive force.

The subject of tractive power of magnets has been extensively developed in Professor S. P. Thompson's "Electromagnet."

The fact that the intensity of magnetic stress varies as the square of the flux density, and that the total stress is the ultimate sum of all the intensities, into the area over which they are exerted, as expressed by the equation $P = \frac{1}{8\pi}\int B^2\,ds$, is the clue to all the most important phenomena of attraction between magnets. It explains, for example, the seeming paradox that an electromagnet will often support a heavier weight from its armature after the contact surface between poles and armature is reduced. For if the flux through the armature is say 20,000 lines, and the polar surfaces two sq. cms. each, the density will be 10,000 per sq. cm. corresponding, by the curve of Fig. 34, to a stress of 4.056 kilogrammes per sq. cm. and the total pull will be 8.11. Since this stress will be exerted at each pole, the keeper should support at a point midway between them a total weight of 16.22 kilogrammes minus its own weight.

LAMINATED OR DIVIDED IRON AND OTHER METALLIC MASSES IN ELECTROMAGNETIC APPARATUS.—VI.

BY

Thos D Lockwood

Joseph Henry.

AT the head of the first list, which patriotically consists of the U. S. Patents, stands the patent of Chas. F. Brush, for his dynamo, No. 189,997 granted April 24, 1877. This patent, speaking of the armature, says that it may be made "of a uniform ring or band of iron, or a bundle of iron wire, or ribbon, or a series of parallel discs with the iron projections between the sections of copper wire." As is well known, the Brush armature core is slit up all kinds of ways, for the suppression of parasitic currents; and this style of construction is more especially disclosed in a second patent to C. F. Brush, No. 203,413, granted May 7, 1878.

This patent states clearly and forcibly the disadvantages of undivided iron in armature cores, and the necessity of dividing them for the purpose of avoiding heat due to currents induced in the iron. It recognizes the former patent, but says this is different, because it insulates the component parts of the core from each other. It will be seen from Fig. 4 that cuts in the iron are made radially, concentrically, and across the thickness; and also that it is contemplated to form the ring from separate flat or separate concentric insulated rings.

Patent No. 209,532 was granted to Edward Weston, Oct. 29, 1878, and is for a dynamo having an armature core which may be built up of discs mounted on a shaft; and which is also longitudinally bisected by a slit to prevent the circulation of induced currents in the core.

In 1879 I find three U. S. Patents showing the division feature. These are: No. 211,611, Jan. 4, 1879, E. Weston; No. 219,157, Sept. 2, 1879, E. J. Houston and E. Thomson; No. 219,398, Sept. 9, 1879, Otto Heikel; all of which are for Magneto or Dynamo Electric Machines.

The Weston specification says that one feature of the invention consists "in forming the armature core of thin wrought iron discs or rings;" and the inventor further states that he builds "up his armature of thin wrought iron discs," and exhibits such a construction, in Fig. 6 of his patent.

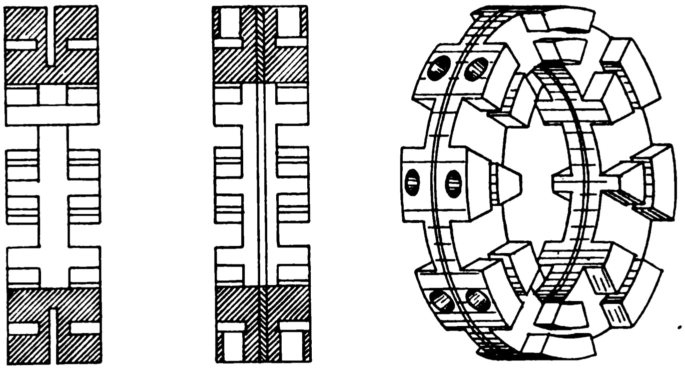


FIG. 4.

In the Houston and Thomson patent, both field magnet and armature core are divided. The specification referring to the former, says: "The cores of the field magnets are made of separate pieces of iron, not in electric contact with each other. This is obtained by forming the cores of plates or rods filed into the desired form, or they are made by rolling a sheet of iron into the desired form;" and referring to the armature, that "its core consists of one or more pieces of iron, of circular or polygonal shape, and provided with projections extending radially outward from them. To avoid heating of the core, many such pieces are placed side by side upon the same axis to make up the armature core in the form of a deeply fluted cylinder."

The armature core of the Heikel patent, to quote the specification, "is composed by preference of rings or of insulated wire wound helically, but it may be a plain iron cylinder."

Five U. S. Patents appear in 1880, requiring notice, viz: No. 223,557, Jan. 13, 1880, Thomson and Houston; No. 226,483, April 13, 1880, J. E. Braunsdorf; No. 228,544, June 8, 1880, H. S. Maxim; No. 232,910, Oct. 5, 1880, Thomson and Houston; No. 223,047, Oct. 5, Elihu Thomson.

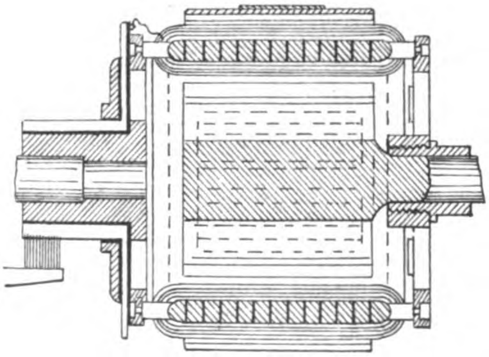

FIG. 5.

These again are all for Magneto or Dynamo Machines, and all comprise divisions of the armature core. They do not, however, disclose features of material novelty, and do not require further consideration; each of them might concur in the statement made by the third, No. 232,910, that "to avoid induction currents in the core, each separate section is constructed as shown, of several separate pieces formed and piled so as to produce the required form."

Nine other exemplifications of the principle appear as U. S. Patents in 1881. These are: No. 242,203, May 31, C. A. Hussey; No. 242,561, June 7, H. C. Sample and F. Rabl; No. 245,900, Aug. 16, E. Weston; No. 247,632, Sept. 27, W. Glass; No. 248,822, Oct. 25, L. G. Wooley; No. 249,017, Nov. 1, J. A. I. Craig; No. 249,148, Nov. 1. C. E. Long; No. 249,634, Nov. 15, C. P. Jürgensen; No, 251,537, Dec. 27, T. A. Edison. These, as usual, are all for Magneto or Dynamo Electric Machines.

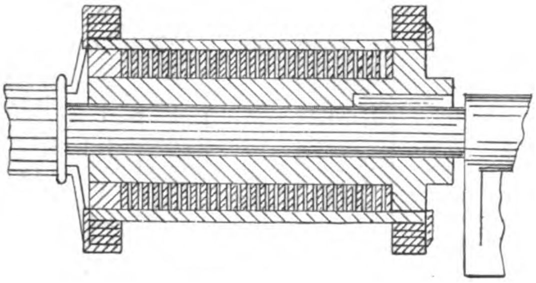

Fig. 6.

Hussey's armature "has a core composed of a number of plates arranged side by side, in close proximity to each other." The Sample and Rabl machine has a ring armature "which is composed of alternate rings of perforated sheet metal E, and wire gauze F, held together by pole pieces G insulated from each other." In the Weston patent the armature is "built up of thin iron perforated plates." The armature of the machine of the Glass patent "is made by winding iron wires round a non-conducting cylinder, and preventing magnetic contact between them by enveloping them with a thin layer of non-magnetic substances." That of the Wooley machine is described as being composed of a series of iron strips or bars magnetically insulated from each other. The specification says: "The armature being composed of a number of iron bars, each bar is magnetized and demagnetized very quickly, thus avoiding nearly all the back-pull common to armatures composed of a large body of iron made in a single piece." These two last instances both emphasize their expectation of facilitating magnetic change.

The Craig patent is noticeable for its full recognition of the prior art, and its rings are made up "by stamping segments out of sheet iron, and piling these segments up into the desired thickness, then forming out of the piled up segments an armature cylinder."

The armature of the Long machine also is formed to facilitate magnetic change rather than to break up eddy currents, and is formed of a number of sheet iron plates alternating with plates of non-magnetic material.

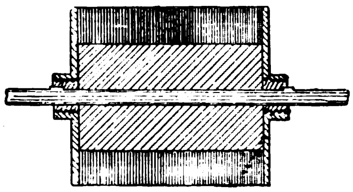

Fig. 7.

The well-known Jürgensen machine has its moving ring made up of plates as shown in Fig. 5. The specification of its patent states that it is preferred "to construct the core of the ring-formed revolving armature of annular or ring-shaped sections, which are separated from each other by rings of hard rubber or other insulating material." The Edison core is built up as shown in Fig. 6, of discs or rings separated by paper; it does not form a prominent feature of this patent, being, as the specification states, described in former applications.

Two more U. S. Patents complete the list; they are: No. 256,778, Apr. 18, 1882, E. Weston; No. 265,785, Oct. 10, 1882, T. A. Edison. The armature core of the former does not differ materially from that of former Weston patents; but that of the latter is noticeable for the extreme care which is taken to insulate each component disc from its neighbor, and the whole from the remaining parts of the machine. The magnetic portion of the core is "composed of iron rings made of thin sheet metal divided by rings of insulating material, tissue paper being preferred for the purpose." Fig. 7 indicates the appearance in cross-section of such an armature.

NON-SYNCHRONOUS MOTOR FOR ORDINARY ALTERNATE CURRENTS.

BY

C. E. L. Brown

After numerous experiments with multiphase motors, I had become convinced, about a year and a half ago, of the possibility of constructing motors for ordinary alternate currents possessing all the characteristics which, till now, have been attainable only by the use of multiphase currents. Among these characteristics of multiphase motors I would specially call attention to the following:

First and most important, absence of collectors and brushes, and consequent simplification of design and reduction in the amount of attendance necessary. Secondly, the possibility of starting the motor against a load; and thirdly, non-synchronous running with the various advantages connected therewith.

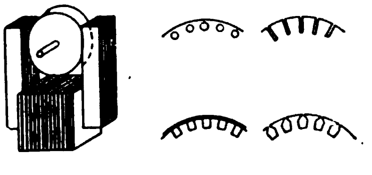
The absence of collectors has in very many cases the result, that the multiphase motor must be considered preferable to the direct current motor, so that, without exaggeration, we may say, that the alternate current (though not, it is true, in its simplest form) is considerably in advance of the direct current as a means of driving motors. When we also consider the ease with which the alternate current may be transformed, we can understand how, in all the newer power-distribution schemes, the alternate current (of two or more phases) has been employed. A disadvantage is nevertheless soon apparent, to which too little attention was at first given, viz., the complication of the mains arising from the fact that more than two wires are necessary. This disadvantage is chiefly apparent in cases of combined distribution of light and power, and creates a demand for a motor for ordinary alternate currents, of equal simplicity with the multiphase motors and possessing their various advantages.

Attempts have not been wanting to produce such motors. This is best seen by the large number of patent specifications filed, in hopes of attaining this end. I do not here propose to consider in detail these attempts, merely remarking, that they have been all more or less unsatisfactory, none of them having, to my knowledge, been adopted in practice. The reason of these unfavorable results seems to be the same as, until recently, prevented the construction of practical multiphase motors. I refer, primarily, to the want of attention to the magnetic resistance of the air gap; owing to the abnormal magnetizing current required, the windings, even while the motor was running light, became so warm that continuous running was out of the question. The efficiency was also, consequently, very low. I have, as is well known, by placing the wires in holes through the iron (both of the fixed and rotating parts), entirely overcome this difficulty, and thus produced the first really practical multiphase motor. Another defect was in the form of the magnetic circuit, with salient poles which produced injurious reactions in the induced part, rendering the starting of the motor very difficult.

I would also call attention to another point, which is specially noteworthy in American practice, viz., the high frequencies commonly employed. This causes difficulties from the great counter E. M. F. of self induction, as well as from the inconveniently high number of poles required on small motors, in order to avoid excessively high speeds. There are several other reasons why these earlier experimenters have failed, but I have, I believe, enumerated the most important above.

After these preliminary remarks I will now proceed to describe my new motor, first noting the remarkable phenomena upon which the principle of it is based. I have observed, that a conductor, placed in a alternating field, (see Fig. 1) if set rotating with a certain velocity, will itself run up to practically synchronous speed, and then has the tendency to keep to this speed against a load. Currents are induced in the conductor by the alternating field. So long, however, as it is at rest, these currents are neutral with regard to the inducing field. As soon as the conductor is set in motion this condition ceases, and a turning moment is produced, which increases as the speed rises, till synchronism is nearly attained.

The following points should here be noted: With a conductor in the form of a solid disc, for example, the speed will drop more or less below synchronism, according to the load. With a deeply serrated conductor, on the other hand, or one consisting of but few members, the tendency is to preserve almost exactly synchronous rotation, and if the speed once falls much below this the torque is considerably reduced.

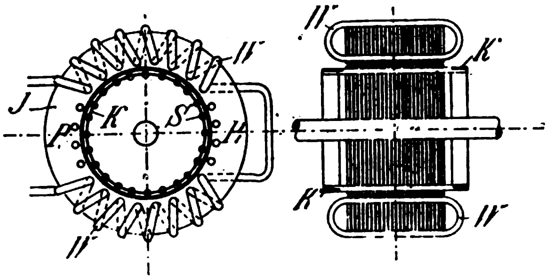


Figs. 1, 2, 3, 4 and 5.

It must also be noted that the direction of rotation is quite indeterminate. The conductor tends always to attain synchronous rotation in the direction in which it was first set in motion. The arrangement shown in the diagram Fig. 1 is, of course, not suitable for practical motors. In designing a motor based on these facts, the following points must be kept in view. The alternating field must be as strong as possible and all magnetic resistances (as well in the inducing as in the induced parts) must be reduced to a minimum. Injurious eddy currents in both iron and copper must also be avoided as much as possible. These various requirements can be satisfied in the following manner: The inducing winding (*i. e.*, that in connection with the mains) as well as the induced (receiving its current by induction from the former) is provided with iron cores consisting preferably of iron discs insulated from one another.

In order to reduce the magnetic resistance, the windings are embedded in iron, either in holes of suitable shape, Fig. 2, or between teeth, Fig. 3, which may be advantageously closed by a winding of iron wire, (Fig. 4). The teeth may also, as in Fig. 5, be widened, so as to nearly close the opening. Either inducing or induced parts may, of course, be provided with either of these arrangements.

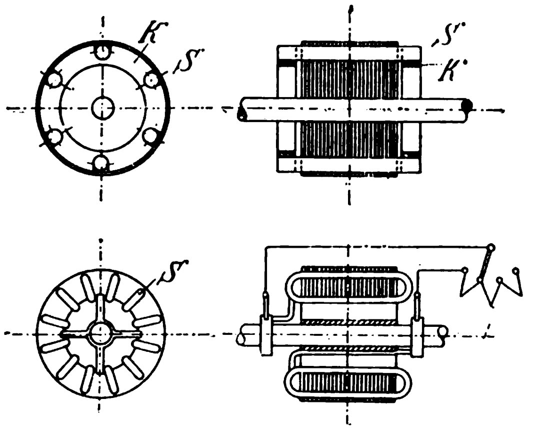
The inducing winding may be, of course, of any of the usual forms, with a suitable number of poles, the sections being connected in series, parallel or in a combination of both. The induced, which is usually also the rotating part, since sliding contacts are thereby avoided, carries a short-circuited winding preferably insulated from the core, in order to avoid eddy currents. This short circuiting may be carried out in various ways. All the ends at each side may be connected together by means of two copper rings, or the conductors may be connected in certain groups, which are separately short circuited. Or, again, wires similarly situated with regard to the external field may be separately short circuited with one another. Another method is to wind the induced part as ring, drum, etc., with a short circuiting connection. For regulating the speed a resistance, choking coil, or a capacity may be inserted in the short circuit.



Figs. 6 and 7.

Figs. 6 and 7 serve to show the most important points about a motor designed on the above principles. The inductor J is shown fixed, and consists of a cylindrical core of laminated iron. The discs, of which it is built up, are perforated near their inner edges and carry the winding W, here shown as a ring (it could, of course, equally well be wound as a drum). The winding is not shown extending over the whole ring, but there is nothing to prevent its being so arranged. The connections are such, that poles are produced at P P'. The rotating part consists principally of a laminated iron cylinder carrying insulated copper wires S in holes close to its circumference. These wires are soldered at each end to stout copper rings K.

A somewhat different arrangement is shown in Figs. 8 and 9. This has the property, described at first, of almost synchronous running. Here again copper conductors S are bedded in a laminated iron core and soldered on both sides to stout copper rings K, the only difference being that the number of conductors is here very small.



Figs. 8, 9, 10 and 11.

Figs. 10 and 11 show another type of rotating induced part, provided with a ring winding S. Two opposite points are here connected to sliding contact rings, so that a resistance for regulating the speed may be readily inserted.

A motor constructed according to the above principles and suitably proportioned has a remarkably high weight efficiency. I have designed a non-synchronous motor, for example, weighing only 150 kg., which at about 2,000 revolutions could be loaded to 6 h. p. without excessive heating. Its efficiency is very good and the apparent watts are but very slightly more than the true watts. The outside dimensions of the motor without pulley are: Length (along shaft) 430 mm.; greatest height 350 mm.; greatest breadth 340 mm. These figures suffice, I think, to show that the output of this form of motor is scarcely behind that of one for direct or multiphase currents.

I may here briefly touch upon an important point, viz., the predetermination of the so called "idle" or magnetizing current, as it is, of course, necessary, in designing a motor, to be able to calculate this current. Experiments with a large number of motors of various outputs show that this may be done with sufficient accuracy for practical purposes, the observed currents differing in most cases by only a very small percentage from their calculated values. The same principles hold here as in the design of ordinary dynamo machines.

A convenient formula for determining the necessary values is that of Kapp (in his paper on "Alternate Current Machinery"). It is as follows:

$$V = C \sim L\, W.\, 10^{-8}.$$

Where

V = E. M. F.

C = a coefficient expressing the ratio between the E. M. F. of alternate and continous current machines.[1]

$\sim$ = Number of complete cycles per second,

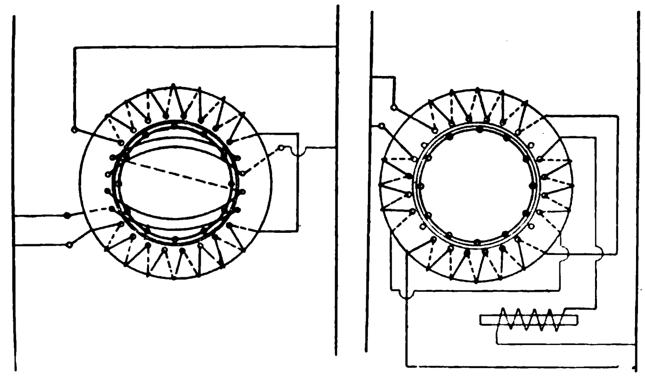
L = total number of lines per pole,

W = total number of wires in the inducing part.

By substituting the values of V, C and W, we may find L, the total induction, and from this the density of the lines both in the fixed and rotating parts, as well as in the air gap separating them. The mean length of the lines is taken at once from the drawing; and from these data, by the wellknown method of Hopkinson, the ampere turns necessary to produce this magnetization can at once be found. The number of wires being given, we thus have the value of the idle or magnetizing current.

Having found the current required to run the motor idle, we may easily determine with sufficient accuracy that required with a load. We may do this as with transformers having open magnetic circuits, since in both cases the idle current lags 90° behind the working current. We have the following equation:

Resultant current with any load $= \sqrt{I_i^2 + I_w^2}$.



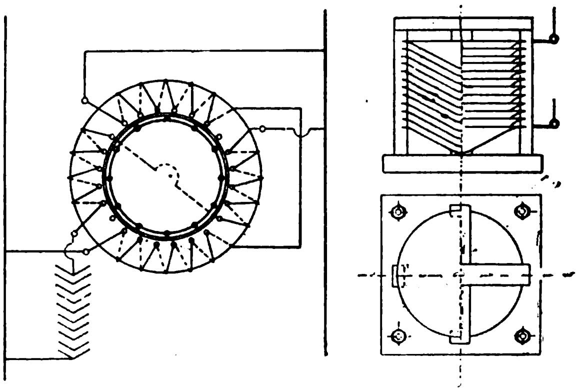
FIGS. 12 AND 13.

Where I_i = idle current,

and I_w = working current.

If, for example, a motor takes 30 amperes idle current and 100 amperes working current, we have for the resultant current $I = \sqrt{30^2 + 100^2} = 105$ approximately; that is, but few per cent. more than the working current. As regards induction in the iron, current density in the copper, etc., similar rules apply as for ordinary dynamo design.

As it would have occupied too much space to go at length into all the questions involved in the calculations for these motors, I have above merely sketched out the broad principles, upon which they rest, wishing especially to point out, that the calculations for such motors are similar to those which have long been in use for direct current machinery.



FIGS. 14, 15 AND 16.

I may add, that what I have said above applies equally to multiphase motors, and in fact it should be clearly understood, that with both broad types of motors, the same principles apply throughout.

A motor designed in accordance with the principles described above has properties similar to a multiphase motor, *i. e.*, has no collector, runs non-synchronously, and, as far as efficiency and output are concerned, is also very similar. In one respect only does it differ considerably from a multiphase motor, viz., it will not start itself, and some method must therefore be found of neutralizing this disadvantage. There are various ways of doing this of which I will describe a few.

The motor may, for example, be provided with a second winding, wound in the spaces of the first, and which, being only a short time in action, may be of relatively small section. By giving this winding a different self-induction to the first and connecting the two in parallel, the resulting phase-difference produces a rotating field, starting the motor and bringing it up towards synchronous running. This second winding can now be cut out and the motor continues to run as a single phase motor as shown described. The difference of phase in this second winding can be attained in various ways. One method is to wind one section as a drum and the other as a ring, as shown in Fig. 12, as it is well known that the latter has considerably greater self induction than the former.

We may further attain the same end by connecting a self inductive device, Fig. 13, or capacity, Fig. 14, or a resistance in series with one section. This method may of course be used in conjunction with the above described mixed winding. In order to obtain conveniently the necessary capacity, we may use a series of elements, which Messrs. Stanley and Kelly have also lately employed in their experiments with alternate current motors. A very convenient form of water capacity consists of a large number of iron discs dished out to a conical form, piled together with insulating distance pieces to allow room for the liquid. (See Figs. 15 and 16.) A solution of soda in water may be employed for filling. As a further method of obtaining the necessary difference of phase, suitably proportioned transformers may also be employed.

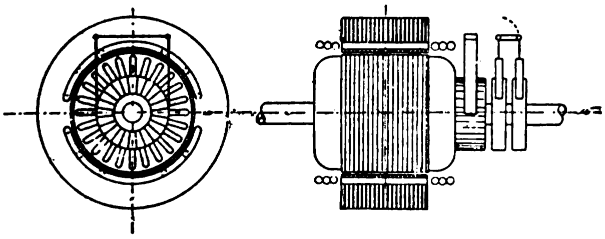
By means of this difference of phase, in a suitably proportioned motor, a very considerable starting torque may be obtained. Thus I have succeeded in getting, with a 1 to 1½ h. p. motor, a torque corresponding to a load of 3 h. p. at full speed.

---

[1] In the above mentioned paper will be found the values of C for various cases commonly occurring in practice.
Herr Görges has extended this table, giving values for other cases. (*Elektrotechnische Zeitschrift*, 1892.)

Another method of starting single phase motors consists in providing the induced, usually the rotating, part with a winding connected with a collector Figs. 17 and 18. By means of suitable brushes we may either supply this winding with current from outside or the brushes may simply be short circuited. As soon as the latter are in their proper position with regard to the external field a powerful torque is produced and the motor starts. As soon as a sufficient speed is attained, the collector may be short-circuited by means of brushes pressing on contact rings connected with opposite points of the winding. Or the winding may be short-circuited by means of a conducting ring brought into contact with the collector. The motor then works in the manner described above. In this case the inducing part is wound in the simple normal manner, *i. e.*, it requires no second winding, for the purpose of obtaining a difference of phase. On the other hand, the induced part has, instead of its simple short-circuited winding, a drum or ring winding, or it may be wound like the armatures of the Thomson-Houston or the Brush arc light machines.

Having now described a few methods by means of which the motors may be started, I must not omit to say, that these non-synchronous motors for ordinary alternate currents may be built of any size, from quite small types to machines of 100 h. p. and more. I believe, that I shall not go too far, when I say, that in the above described simple motors, we have a means of securing the speedy and certain extension of the use of ordinary alternate currents. These motors will be especially employed where light and power together must be supplied in the simplest manner possible.



FIGS. 17 AND 18.

As regards amount of attendance necessary and safety in running, these motors are considerably in advance of those for direct currents, and as regards commercial efficiency for the same size, output, and speed are equally good. I am of the opinion, that this new type of motor will displace multiphase motors in all those cases, where in addition to general lighting, power must be supplied, while for power distribution alone the multiphase motors will still find a use. In light and power distribution systems, having the so-called two phase current, an advantageous combination of the two types of motor may be made. Thus small motors may be connected simply to one phase like the lamps, while larger motors could be connected to both phases. I have now, I believe, described briefly the principal points of this type of motor; it is not yet possible to go further into details, especially as several questions with regard to patents are still to be settled. However, I hope that it will be possible before long to give a more detailed description of some large installations, employing this type of motor.

STARTING THE LIVERPOOL ELEVATED ELECTRIC RAILWAY.

ON Saturday, February 4, the Liverpool electric "elevated," which has already been described and illustrated in our pages, was successfully started, Lord Kelvin, the Marquis of Salisbury, and many other notables being present. The trial trip over the road was made at a speed of 22 miles an hour. The road runs along the river Medway and docks' front, and is a massive iron structure with occasional viaducts. It ends in a handsome terminal depot. The motors are under the cars, and the current is picked up from track conductors. There are several stations along the line. An interesting feature of the road is the manner in which it traverses drawbridges and tilting bridges.

A NEW RULE FOR DETERMINING THE DIRECTION OF INDUCED CURRENTS.

BY

Herman A. Strauss.

IN attempting to explain the phenomena of induction to minds just beginning to grasp the abstractions of the science, I have found that Dr. Fleming's "Hand" rule for remembering the connection between motion, magnetism and induced current often confuses the student, seemingly from the lack of exactitude attending the attempt to portray the three rectangular axes by means of the fingers and thumb.

Compelled to find some more striking representation and anxious to remain consistent, I have produced the following rule, which, from the good results it has yielded me, may perhaps prove useful to others. It reads thus:

Stand in the direction of motion, so that the line of motion traverses the body from the feet to the head.

Look along the Lines of Force, that is, face the South pole. Extend the left hand to the left. The induced current will then be leaving the fingers of the extended hand.

RAILWAY TELEPHONY.

MR. C. A. HAMMOND, superintendent of the Boston, Revere Beach & Lynn Railroad, in a recent paper published in the *Railroad Gazette*, calls attention to the growing tendency among railways to the use of the telephone in place of the telegraph in the transmission of train orders; and he urges its wider adoption for the purpose. Within the past year or two, the entire telephone service of his road has been changed to copper metallic circuit, using long distance transmitters with sufficient battery power to allow a dozen or more instruments to be placed on a single circuit; individual calls being distinguished by long and short rings as in the Morse code. Care has been taken to neutralize induction, and the line is found to be perfectly quiet day and night. The writer is of the opinion that there is no reason why the telephone, if proper precautions are taken, is not preferable to the telegraph for this class of work. The rule has been for the sender of a message to write it down as he talks and have the receiver write down what he hears, repeating the message as a check. As an instance of working of the system, Mr. Hammond states that he has on file 2,500 train orders in which there is not a single error of vital importance.

ARC LIGHTS AND LONDON FOGS.

A LONDON electrical paper states that arc lighting for streets has received a remarkable vindication during the recent heavy fogs in London, and it quotes from the daily papers a description of the excellent service rendered by the electric light through one of the heaviest fogs of an exceptionally foggy year. The electric light is practically only just coming into use in the London streets, yet an opportunity was afforded on the day in question to establish a fair comparison of the relative merits of gas and electric light in a dense atmosphere. An unanimous decision was recorded in favor of the electric light, and it is further stated that men who have spent the whole of their lives in the city of London were of opinion that the traffic in the streets which during a fog is always more or less impeded, and sometimes brought almost to a standstill, was facilitated by the increased power of illumination to an extent never before known.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed, and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XV. NEW YORK, FEBRUARY 8, 1893. NO. 249.

ATTITUDE OF THE GENERAL ELECTRIC COMPANY.

THE ELECTRICAL ENGINEER has great pleasure in directing the attention of its readers to the subjoined letter of the General Electric Company.

GENERAL ELECTRIC COMPANY
44 Broad St., New York.
620 Atlantic Ave., Boston.

Office of Assistant General Manager.

NEW YORK, Feb. 3, 1893.

To the Editor of "THE ELECTRICAL ENGINEER,"
203 Broadway, City.

Dear Sir:—The spirit of fairness which has always characterized your paper will probably lead you to give us an opportunity to comment on an article under the head of "Legal Notes" in your paper of Feb. 1st, which seems to us to convey an absolutely false impression.

The circular issued referring to Supply Houses and other middlemen cannot be said to disclose any policy on the part of this company. The difficulties of the present situation are such that we have been obliged for the time being to refuse to sell lamps except to the users, because in no other way can we meet our obligations to the licensees of the Edison Electric Light Company, whose contract rights must be respected, and who have sent us frequent complaints that Edison lamps were sold in their territory where they have the exclusive right to use and sell, without their knowledge or consent. We recognize, and believe that the public will recognize, that the Edison Licensees have definite and absolute rights which they are entitled to enforce. Certainly neither the General Electric Company nor the Edison Electric Light Company has any right or power to interfere with its licensees in such action as the latter may deem wise for their own interests.

The suggestion that the General Electric Company has notified "various parties that if it does not get the order for generating apparatus the supplies of necessaries to run it, so far as the General Electric Company controls such supplies, will be withheld," is entirely without foundation. In the present situation of the lamp litigation it is impossible to adopt a general policy applicable to all or to the majority of cases, and the General Electric Company certainly is in no position to announce a policy until it has formulated one. For the present we propose to use every effort, first to protect the licensees of the Edison Company in their vested rights, even at the sacrifice of the large amount of business that would otherwise come to us through the Supply Houses; and second, to meet each user of incandescent apparatus who desires to purchase lamps of us, fairly and endeavor to accommodate him, if possible.

Yours truly
S. D. GREENE,
Ass't Gen'l M'g'r.

That portion of the letter referring to the Company's circular addressed to supply houses and others, in which it declines until further notice to fill orders for lamps except when coming from actual users, may properly be read in connection with Mr. Grosvenor P. Lowrey's assurance to the Court, in the course of his argument for complainants in the Sawyer-Man case a few weeks ago, that he "was "authorized to say that it was not the intention of the "General Electric Company, or of the complainant [the "Edison Electric Light Company], to refuse to sell lamps "for use on Westinghouse machines. They desired to sell "their lamps everywhere, had put them in the hands of "supply dealers for sale and did not intend to take them "out of the supply dealers' hands; anybody who wanted "to buy them would continue to find them there." It is gratifying to be assured by the General Company, that its withholding of lamps from dealers and all but actual users is not to be taken as disclosing a permanent policy, but is for the time being only; pending—it is to be inferred from the above letter—some adjustment of the difficulties arising from the contract obligations between the General Company and the Edison licensees. No reasonable persons, however interested, will gainsay the right of such licensees to protection under the Edison patent while it is in force, or fail to recognize the complexity and difficulty of the present situation for the General Company; difficulty and complexity, however, not too formidable for solution by the ability, administrative and legal, at the command of that company. Its intention of good faith toward its step-children, the Edison illuminating companies, now so explicitly declared, was never to be doubted.

The General Electric Company pronounces the suggestion that it had notified parties that if it did not get their orders for generating apparatus it would withhold lamps and other necessaries to be "entirely without foundation;" and says that in the present state of the lamp litigation "it is impossible to adopt a general policy applicable to all or to a majority of cases;" that it cannot announce a policy until it has formulated one. This denial is, of course, to be accepted. We fear, however, that some of the Company's agents or representatives, in the heat of competition for business, have been less reluctant to adopt a policy and have ventured the attempt to forestall the purchase of competing dynamos and other plant by threatening to shut off the supply of lamps. We are glad to be assured that nothing of this sort is sanctioned by the General Company. The allusion in the letter to the present situation of the lamp litigation is very significant. Judge Colt, in Boston, is considering whether a preliminary injunction shall be put upon the Beacon Company in view of the evidence of the alleged Goebel prior use brought forward by the defendants; while Judge Grosscup, in Chicago, announces his purpose, in his jurisdiction to see to it that users get lamps, if not from the Edison people then from the Sunbeam Company or from others. A decision in the Boston case, adverse to the complainants, would apparently at once clarify the present muddled situation and relieve users of incandescent lamps, and dealers in them, of all concern respecting the policy of the General Electric Company. The confessedly short term remaining to the Edison patent would probably expire before the Beacon case could be disposed of should it go to a final hearing without a preliminary injunction. No one can safely hazard a prediction as to whether the court will grant or withhold an injunction.

WAS GREEN A GOEBEL?

UP to the present time the electric railway field has been the scene of but little active legal warfare, as to patents, but indications are not wanting to show, that the present skirmishes may soon lead to a general engagement along the whole line. The consolidation of the Edison and Thomson-Houston railway interests has served to bring under single control a large number of patents relating to this important branch of work, but, as noted elsewhere in this issue, it would seem that the General Electric Company has deemed it expedient and necessary to further fortify itself for the struggle to come by the purchase of the Green patent. In viewing the present situation of affairs, there appears to be a striking analogy between the cases of Green and of Goebel. Both were intelligent dabblers in electricity long before either incandescent lighting or electric railroading became commercial actualities through the genius of other men, and both claim with much plausibility to have produced actual working devices embodying essentially the fundamental elements of the apparatus of to-day. It is true that in the case of Green a patent just beginning to run, was issued as the result of a prolonged interference in the patent office; but if, as is more than probable, a legal contest should be based on this patent, the General Company would find itself in the anomalous position of being a stout supporter of the claims of one inventor whose crude work was in many ways quite analogous to that of another, whom, they are now, and quite properly, strenuously opposing. It is a curious situation. The patent situation in the electric railway field bids fair to become quite as complicated as that of electric lighting in its palmiest days, as there is pending even now a suit based on the broad patent issued to Mr. Stephen D. Field, in which, as shown elsewhere, the employment of a dynamo electric generator is specifically claimed.

THE WORK OF THE PIONEER.

WHATEVER it may be in other fields, it is certainly true that in electricity the pioneer "never dies" from sight. Sooner or later his work is recognized and justice is done him. Our own pages have frequently contained the historical record of work that had been buried and wellnigh forgotten, and that awaited the careful search of the later investigator. At the present time when so much is being claimed and based, for purposes of legal offence and defence, on old work and old ideas, it is a pleasure to be able to print, solely for its personal and reminiscent value, to the interesting series of articles that Mr. W. J. Hammer has prepared for us on the pioneer electrical work of William Wallace. The wonder is that, having begun so early and so well, Mr. Wallace did not continue. As a matter of fact, he has kept pace with electrical growth, but he has not been the direct participator in it that one would expect on reading the really marvelous record that Mr. Hammer gives of his pioneer investigations and practical machines. It is a positive misfortune for the industry that so farsighted, able and wealthy a pioneer had other duties and interests. It must be evident to all that Mr. Wallace once held the dynamo industry in this country in the hollow of his hand. There is one great lesson in this narrative and in all the exciting events of the past few weeks, and that is, that it pays an electrical inventor to hold on and push on and then hold on again. In the lexicon of the electrical inventor, there must be no such words as "abandoned experiments."

THE INCANDESCENT LAMP LITIGATION.

THE interest in electric circles in respect to the outcome of the motion for injunction against the Beacon Company of Boston continues unabated. All the papers and exhibits in the case were submitted to the Court on February 1, and the case was then closed. We print in this number full abstracts of all the more important of the large mass of affidavits presented to the Court in behalf of and against the motion, together with illustrations of the two most important exhibits, and a synopsis of the proceedings at the supplementary hearing before Judge Colt, in Boston, on Wednesday last. From these articles our readers will be able to gain an accurate idea of the present aspect of this most remarkable case. At the time of going to press no decision has been reached, but it can scarcely be delayed more than a day or two longer at most. If the General Electric Company are entitled to an injunction, it is to be hoped it will be given them with all promptitude. The company and the electrical public will then have a clearer idea as to things.

THE THREE-WIRE PATENT SUSTAINED IN ENGLAND.

THAT legal struggles in the electrical field are by no means confined to our shores is evidenced by a recent decision given in England sustaining the validity of the three-wire constant potential system of distribution. This system, patented by Dr. John Hopkinson in England, was the subject of a suit brought by Dr. Hopkinson against the St. James and Pall Mall Electric Light Co. (Limited), of London, and the defence, it is interesting to note, was undertaken by an association of electric supply companies. Mr. Justice Romer in giving judgment in favor of Dr. Hopkinson, dwells mainly upon three points, namely, first, whether the patent in question was designed to cover the parallel system of distribution; second, whether it had been anticipated, and third, whether it embodied any patentable novelty, considering the state of the art at that time. On all these points the patent is sustained. Curiously enough, the Hopkinson three-wire patent in England is owned by the Westinghouse Company. In this country a suit to test the validity the Edison three-wire patent has been pending for some time and much of the testimony already introduced is similar in character to that brought out in the English case.

A METHOD OF CORRECTING THE REGULATION CURVES OF GENERATORS.

BY

Geo. L. Thayer.

One of the most serious difficulties met with in testing direct current dynamos is the difficulty of keeping the machine up to speed. When the design of new machines depends upon the results of a test it becomes very important to know just what the regulation is going to be, especially in the case of compound machines. The E. M. F. is by no means proportional to the speed in self-exited machines. The well known fact that compounded machines are very sensitive to variation in speed of the engine shows this. A variation in dynamo speed due to engine regulation and belt slippage of less than two per cent. will quite destroy the self-regulation of the machine.

In the case of separately excited and arc light machines the E. M. F. may be assumed to vary as the speed, and the curves from the machine may be connected accordingly. With a shunt machine this cannot be done. A change in speed in such a machine causes a change in E. M. F. considerably greater. This variation may be classed under two heads: First, that due to the change in speed, assuming the field to remain the same; and, second, that due to the increased strength of field due to the first change. Now if this ratio can be found, the E. M. F. of a machine can be computed accurately enough for all practical purposes, when the speed varies.

Call this ratio r.

Let $E =$ E. M. F., as observed;

" $E_1 =$ E. M. F., corrected for speed alone;

" $E_2 =$ E. M. F., corrected for speed and change in strength of field.

Let $T_w\ C =$ ampere turns in shunt coils as observed;

" n and $n_1 =$ observed and standard speeds, respectively.

From the magnetization curve in the region in which the E. M. F.'s will lie, find the ampere turns on the field necessary to produce a change of one volt. Call this value T. When working near the knee of the saturation curve the mean value for the probable range of E. M. F. should be taken. The new E. M. F. due to change in speed alone is

$$E_1 = \frac{n_1}{n} E.$$

The change in E. M. F. due to the change in field strength alone is, since the shunt field current varies as the impressed E. M. F.:

$$E_2 - E_1 = T_w\ C\ \frac{E_1 - E}{E} \times \frac{1}{T}.$$

By definition $r = \dfrac{E_2 - E_1}{E_1 - E}$.

Substituting and applying Ohm's law.

$$r = \frac{T_w\ C}{E \times T} = \frac{T_w}{R} \times \frac{1}{T}.$$

R is the resistance of the field plus the portion of the rheostat in use. As the temperature of the field changes the resistance, R is best computed from the observed values of E. M. F. and field current.

The E. M. F. corrected for speed and change in field excitation is then

$$E_2 = E_1 + r\,(E_1 - E).$$

But this does not take into account the change in field current in passing from E_1 to E_2. This further change in E. M. F. is evidently

$$r\,(E_2 - E_1) = r^2\,(E_1 - E).$$

This series of approximations may be continued, giving

$$E\ (\text{final}) = E_1 + (r + r^2 + r^3 + \text{etc.,})\ (E_1 - E).$$

This series is always a converging one and the equation then takes the form

$$E\,(\text{final}) = E_1 + \frac{r}{1 - r}\,(E_1 - E).$$

This value is an approximation but it is within the limits of errors of observation. The value of the series will run from 0.5 in machines with a large air gap, or working above the knee of the saturation curve, to 1.5 when the field is not saturated.

The value of the coefficient of $(E_1 - E)$ is a function of the number of ampere turns necessary to change the E. M. F. one volt. If the E. M. F.'s vary greatly and if the generator is working near the knee of the saturation curve, it may be necessary to compute more than one value.

A modification of this formula can be used in correcting the regulation curves of composite-wound alternate current generators; but where the composite winding is small the value of the coefficient is small.

This method has given good results in the plotting of regulation curves from large compound multipolar generators. In a few cases where steam had dropped just before the last points of the curve were taken the corrected E. M. F.'s resulted in a satisfactory curve although the drop in speed was almost 10 per cent.

ELECTRIC RAILWAY DEPARTMENT.

"TROLLEY WIRES NEED NOT HINDER FIREMEN."

BY

J. Stanford Brown.

In a recent number of a contemporary appears an article headed "Trolley Wires Hinder Firemen."

I am glad to see mention of this subject in the electrical papers because the appearance of such articles in the technical press refutes the statement so often ignorantly made that the "facts" and "faults" of the trolley system are not fully portrayed in the electrical journals.

An additional word on the subject should serve somewhat to allay the fears of those who still insist upon the "deadliness" of the trolley.

With a proper system of guys, etc., in line construction and a specially trained and equipped "Emergency Force," who are to be rung out together with the city fire department and the insurance patrol, no delay or extreme danger need be incurred by the firemen. Such a force must needs be maintained by all street railway companies operating a trolley system of any magnitude in our large cities. I do not think the city firemen should be either obliged, or permitted, to cut down wires at a fire. An experienced crew of six men with a speed-wagon and two or three extension ladders could "loop" the feeders around a batch of several buildings, drop the feeder cut-out into the gutter, and cut out the corresponding trolley and guard-wire sections in very close to as many seconds as it takes the firemen to get out their hose and couple up to the hydrants with pressure through their engines.

Of course the potential drop on that section might be increased for the time being, for the temporary wraps would not be soldered and the cars would be thrown slightly off their schedule. With a supply of "hose jumpers," however, and an amicable understanding between firemen and the emergency gang, but few lines would cross tracks; and the cars being within "police lines" could be safely shot across the break in the trolley wire. The line superintendent would be on hand to direct, and together with his foreman, should be a "special officer." This would ensure respect from citizens getting in the way before the arrival of police reserves.

In short, while there is a chance for some annoyance from wire in cases of fire, there is still a way of reducing it to reasonable bounds and it only remains to be determined by the demands of public convenience and safety what shall be considered reasonable bounds—for *the trolley is here to stay.*

THE ACQUISITION OF THE GREEN ELECTRIC RAILWAY PATENTS BY THE GENERAL ELECTRIC COMPANY.

THE announcement that the General Electric Company has acquired the patents on electric railways issued to George F. Green, and claimed to control vital features in this method of propulsion, adds an additional interest to the existing state of electrical affairs.

Green, it would appear, was one of those mechanics of whom this country has furnished many conspicuous examples, who dabbled in electricity and got up numerous devices having in view the application of electricity to the propulsion of vehicles. At the age of 21 he went to Kalamazoo, Mich., and opened a small machinist's shop. In 1856 he occupied a small room in the corner of the post office building in that city, where he operated some small electric motors of his own construction by means of batteries. He went so far even as to build a small circular track, upon which ran a small car driven by electric motors. The wires from the battery were connected to the rails, the positive pole to one rail and the negative to the other. He also stated that during that time a magneto generator came into his possession, the current of which he rectified and by which he operated the car on his track.

In 1865 he removed to another shop and was occupied largely in building electric appliances for operating dental instruments, sewing machines, and also continued work on his electric railway. The latter was frequently exhibited to people with the object of inducing them to assist him further in raising the money necessary to put up a large track with cars on it, and for the purchase of a dynamo in place of battery, which he recognized to be impracticable for heavy work.

About 1875 Green succeeded in raising capital sufficient to put up on the grounds where his shop was located in Kalamazoo, an elevated track a little over 200 feet long, the rails of which consisted of strap iron nailed to stringers of seasoned wood. These stringers were some five inches apart connected with cross pieces. The rails were connected to a battery on the inside of the shop, the end of the track coming up to the window of the shop.

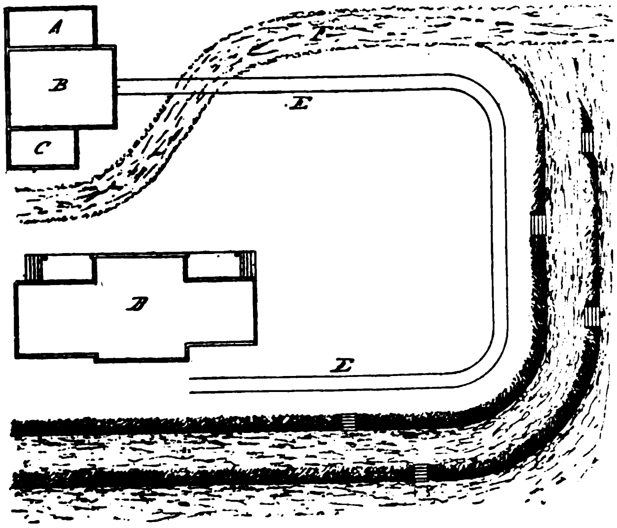

FIG. 1.—DIAGRAM OF GREEN'S ELECTRIC RAILWAY TRACK, 1875.

The accompanying diagram, Fig. 1, shows the location of the track; B being the shop, and E E the track. The arrangement of the circuits was such that the current passed from one pole of the battery to one rail, through the wheels to the motor, and then passed out through the other wheels into the opposite track and back to the other pole of the battery.

This car, according to the sworn statement of Mr. Green, had a reversing device that was capable of three positions, two for reversing and one for breaking the circuit. As the car ran out of the shop window down quite a steep grade it reached a level portion of the track, and at the distant end the reversing lever would strike a finger on the track rail that would reverse the car and send it back again to the shop window. This car was able to carry a load of about 100 pounds.

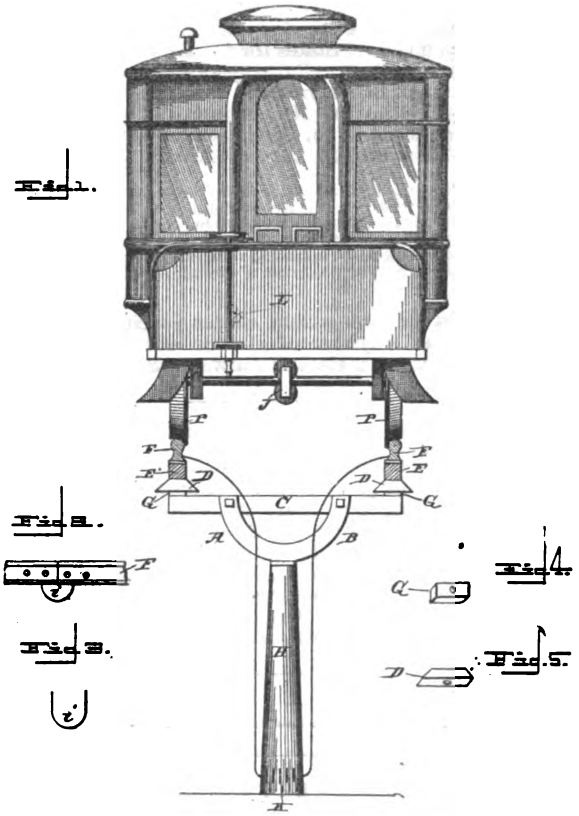

FIG. 2.—DRAWINGS OF GREEN'S ELECTRIC RAILWAY PATENTS, No. 465,407.

It may be mentioned here that the *Kalamazoo Daily Telegraph* of Oct. 7, 1875, contained an editorial entitled "Rapid Transit in Kalamazoo," which makes mention of Green's railway and suggests its application to the existing needs for rapid transit in New York.

Shortly after the completion of this small car, Green built what he termed a "flat car," with a platform about 6 feet long and 4 feet wide. This was also provided with a reversing switch and a safety device for preventing the car from starting off accidentally. This car had four electric motors attached by gears to the same axle.

During all this time Green declared he was making efforts to secure a dynamo, and states that he actually went with one of his financial backers to the Western Electric Works at Chicago, and operated his motors by current derived from a dynamo electric machine in operation at those works, in order to demonstrate the increased power of such machines over batteries.

On Sept. 15, 1879, Green applied for a patent which, after much delay in the Patent Office, caused by interferences, was issued on Dec. 15, 1891, No. 465,407, entitled "Electric Railway." This patent, the drawings of which we reproduce in the accompanying engraving, Fig. 2, has four claims, the scope of which will be seen by a perusal of claim 3 which reads as follows:

> 3. The combination, substantially as set forth, of a railway track, one or more stationary means of electric supply, electrical conductors extending from said means of electric supply along the lines of said track, and consisting wholly or in part of the rails thereof, vehicles movable along said track, electrodynamic motors fixed upon said vehicles for imparting motion thereto, and wheels supporting said vehicles upon the track, and also serving to maintain continuous electrical connection between said means of electric supply and said motors, substantially as described.

As was remarked above, Green employed a reversing device on his car, and the scope of his claim in this direction can be gathered from the first claim of the patent issued to him, entitled "Electric Railway," No. 465,432. This patent was filed May 15, 1886, and issued Dec. 15, 1891. The claim reads as follows:

> 1. The combination of one or more stationary sources of electrical current, a conducting circuit formed wholly or in part of an insulated line of rails of a railway track, a wheeled vehicle movable upon or along said line of rails, one or more rotating electric dynamic motors mounted upon said vehicle for propelling

> the same and included in said circuit of conductors, and a circuit-controller placed on said vehicle and also included in said line of conductors, substantially as described.

For a long time prior to his death, which occurred last year, Green was aided financially by Mr. Oliver S. Kelley, of Springfield, O., and to whom both these patents were assigned. The acquisition of these patents by the General Electric Co. is claimed by them to put them in a position to control all electric railways operated by the trolley system and handled by means of controllers on the cars.

We may add here, however, that a suit is now pending in the Circuit Court of the United States for the Eastern District of New York, brought by the Electric Railway Co. of the United States against the Jamaica & Brooklyn Road Co. The former are the owners of the patent issued to Mr. Stephen D. Field, July 16, 1889, No. 407,188, and application for which was filed on Mar. 10, 1880. The first claim of this patent reads as follows:

> 1. The combination, substantially as hereinbefore set forth, of a stationary dynamo-electric generator driven by a suitable motor, a circuit of conductors composed in part of an insulated or detached section of the line of rails of a railway track, a wheeled vehicle movable upon or along said insulated section of track, an electro-magnetic motor mounted upon said vehicle for propelling the same and included in said circuit of conductors, and a circuit-controlling device placed upon said vehicle.

It will be noted that this patent claims specifically a dynamo electric generator as a source of electric energy, and hence its owners claim that existing electric railways are subject to it.

A TROLLEY LINE FOR THREE COUNTIES.

A tri-county electric trolley line will be constructed in the spring from Middleburg, Pa., to Watsontown via New Berlin, Centreville, Mifflinburg, Lewisburg and Milton—a distance of 35 miles. Ex-United States Senator, John J. Patterson, of North Carolina, is at the head of the enterprise. The directors of the company are State Senator W. H. Hackenburg, of Milton, S. M. Patterson, of Mifflinburg; Representative B. K. Focht and Register and Recorder H. E. Gutelius, of Lewisburg, Pa. The route has already been surveyed and a charter applied for.

MISCELLANEOUS.

THE BENEFITS OF ELECTRICITY IN MINING.

BY

John McGhie

THE special advantages attendant upon the use of electricity in mining operations of all kinds are never more strikingly shown than during the prevalence of weather such as that to which we have been treated since the beginning of this winter. The temperature has fallen so low in certain parts as to render even the "oldest inhabitant,"—that unimpeachable authority,—incredulous as to the occurence of a severer winter in any of his previous experience. The snowfalls have been unprecedented in their persistency, the ice has accumulated in thicker strata and greater quantity, and what little sporadic thaws have supervened have caused unexpected havoc.

Reports from the mining districts of the less-favored territories show that although mining operations have been beset with great difficulties, yet in all cases in which electricity is the motive power used for the operation of the mine machinery, there has not been an instance of a breakdown; whereas, in former times and under less favorable conditions and methods, breakdowns were a usual occurrence in winter.

Mines operated by steam are subjected to many and various accidents directly traceable to sudden changes in temperature, each one of which is the cause of pecuniary loss to the mine owners and endless trouble and annoyance to the superintendent and his aides. Owners and managers wedded by predilection, or necessity, to the ideas which the progress in scientific knowledge of the last 10 years has relegated to the dusky obsolete, have been compelled to see water pipes burst, pumps choked by ice, boilers disabled, steam pipes damaged, ventilators stopped, stamping and concentrating machinery at rest, and the whole busy, restless life of the mine with its noisy hum, under the pall of a depressing winter silence, which lasts until the more genial warmth of spring arrives to assure the manager that he may begin to effect the necessary repairs without fear of further mishap. If the mine is the property of a company, the shareholders grumble at the loss of time and the non-productiveness of the mine, while the directors are at their wits' end to find rational excuses for the satisfaction of the shareholders.

But a compulsory shut-down of this character at the most inclement season of the year, has effects which reach farther than the pockets of the shareholders or the minds of the directors. Miners thrown out of work are unable to provide for those dependent on them, and wide-spread misery is the result. To forestall this, they are compelled by dire necessity to migrate to other points where subsistence for them and their families can be procured. If, however, the mine owners decide to keep their good men on the pay-roll, the expense entailed constitutes another addition to the already considerable loss brought about by the mere shut-down itself and the consequent non-production, during the season of inanition. If the miners are simply laid off, and migrate, the mine owners are always exposed, on the resumption of work, to the danger of having their mine filled with inexperienced workers and to the possibility of accidents with their ensuing loss.

Thus, suffering in some shape or another is inflicted upon all concerned once winter firmly grasps with icy hand the mine which is operated solely by water and steam;—upon the proprietors or shareholders in their most tender spots, their pockets; upon the miners, their wives and children, the future generation of workers, in their very lives. To these last the playful snowflake and the hoar-frost are realities which few of the shareholders of the ordinary category are able to conceive of, or, if so, to appreciate.

The adaptation of the electrical current to almost all the different methods of mining, and its more general adoption as progressive *fin de siècle* ideas permeate the body social, is effecting a gradual change in mine life which is assuming an aspect so different from what previously prevailed as to astonish those who do not keep well abreast of the swiftly advancing *Zeitgeist*. A stupendous reform is being effected, and the agent thereof is silently, but irresistibly, doing the work. The humble little wire, which runs over porcelain insulators, down into the bowels of the mine, to the points of application of the power, is, to use a celticism, a "fairy godmother." To the mine pervaded by the electrical current come no shut-downs. Bursted pipes are unknown; the whirr of the machinery is ceaseless; there are no stifled pumps. The course of mining operation runs its even way without delay or mishap. The throbbing pump at the extreme end of some deep working thrusts the water to the surface with constantly maintained force; the ventilators continue to supply fresh air, and draw off the deleterious; the cutter tears out without interruption the slot in the coal ledge; the drill merrily pounds its way into the depths of the mineral; the locomotive performs its alloted task, the cage ascends and descends without intermission; and the stamping mill and the concentrator continue their work uninterruptedly. There is no cessation of labor either of man or machine, except at the proper times. Temperature vagaries are indifferent matters of no particular concern either to miners or owners.

The results of an electrical installation in a mine, whatsoever be its character, are immediate and beneficial. Constant work means assurance for the owners and the men, and their minds free from the worry entailed by the ever present dread of a possible shut-down; they are able to think of improvements in operation and even occasionally to consider favorably the pleasing prospect of profits. The physique of the men also improves as the conditions under which they work are ameliorated, and it is incontrovertible that the better the physique, the better the class of labor, and the greater the material results. With the advent of profits, comes the contentment of the shareholders and directors, and, this last assured, the circle of benefit is complete.

From all that precedes a moral can be drawn by those who have ears to hear and eyes to see and recognise benefits when thrust within the range of their vision. Adopt electricity in all mines where possible, and reap the advantages which will as certainly result, as will the sun rise at the break of day.

MR. HARTER ON TRUSTS.

MR. MICHAEL D. HARTER, the Ohio M. C., was recently asked what had become of his anti-trust bill.

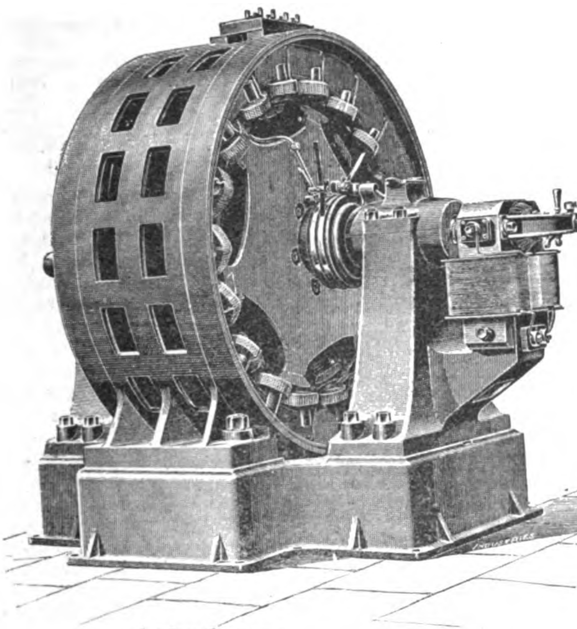
"I think it will become a law some time," he replied, "but I cannot say that it will this session. It is likely to be passed by both houses early in the next session, I think. It is, and ought to be, a stringent measure. We have now one law which aims in some respect to be so, but is has turned out to be a law showing 'how not to do it.' My bill, I think, is very fair and just. If the trust interested chooses to dissolve, it in no way punishes or seeks to punish past offenses. If not, it simply puts the articles made by the trust on the free list, and by way of a penalty strictly annuls all patents exclusively owned by the trust and deprives the trust of all its exclusive rights—in fact, of about all its advantages of good-will, trade marks, etc."

"Will it wipe out trusts?" was asked.

"You can imagine how much of a trust the Sugar Trust would be with from $12,000,000 to $15,000,000 cut out of it and restored to the people each year. What would happen to the Whiskey Trust, with the tariff tax cut down from $2.50 per gallon to the internal revenue tax of 90 cents? Where would the Cigarette Trust go with its patents annulled and its trade marks made public property? I intend to add to the bill, before its passage, the loss of trade marks. As the trusts can escape all these penalties by simply dissolving, it looks to a man up a tree as if the reign of the trust is likely to be only a question of time, and not a very long time, either."

TRIPLE-CURRENT ALTERNATOR.[1]

THE MASCHINEN FABRIK OERLIKON have recently carried out an interesting installation in the town of Pergine, in Southern Tyrol. The generating station is about two miles from the area of supply, and contains a high-speed turbine, with a horizontal axis running at 600 revolutions per minute, and coupled direct to a 100 h. p. triple-current alternator. As the distance over which the power has to be transmitted is small, step-up-and-down transformers are unnecessary, and a pressure of 1,700 volts is used. The generator, which was designed by Mr. E. Kolben, is shown in the accompanying illustration. The field magnet, which rotates, is of cast steel, having 12 poles, excited by a single coil, as usual in the Oerlikon multiple-current machines. Laminated pole-pieces are employed. They are built up of sheet iron stampings and fixed to the cast-steel pole-pieces. The external stationary armature has 18 coils wound in notches of a peculiar shape, coupled up in three sets of six coils each, and the exciter is coupled direct.



OERLIKON TRIPLE CURRENT ALTERNATOR.

The machine regulates within five per cent. without any series excitation, which is an exceedingly good performance. The excitation at full load is 1.1 per cent. of the out-put. Owing to the shape of the pole-pieces, and of the armature notches, the machine hardly hums at all. The total weight of the machine is three tons.

ELECTRICAL RECORDING METERS.—III.

BY CARYL D. HASKINS.

(Concluded.)

There is one other class of clock meter which actuates a dial or recording train, and for the typical instrument of this class we will select the Pilkington-White meter. This instrument has a wheel rotating at a constant speed; into this wheel are inserted a number of pins of different lengths, projected from the face of the wheel parallel to its axis; a lever arm whose position is determined by the indicator mechanism is so placed that it shall engage with these pins. If the load be light it will only engage with the longest pins. If, for example, the load be one lamp, then the lever will engage only with the longest pin. On engaging with the pin, the lever is pushed in the direction in which the wheel is rotating, and gives an impulse of one tooth to the recording wheel. Thus, on the light loads the meter would receive but one impulse for every revolution of the motor wheel, and just in proportion as the load increased, so this lever would engage with more pins and more frequently actuate the recording dial.

This meter is very good in many respects; but it should be noted that it reads to points. There is necessarily a limit to the number of pins which can be used, and with a 100-light meter, having, we will assume, 10 pins, it is clear that there can only be 10 variations in speed from one lamp to full load, consequently the speed will only change every 10 lamps, and we should get the same record on 19 lamps as on 10. The figures which I give for a 100-light meter and 10 pins, are purely arbitrary and not representative of the number used, but are given to indicate the idea which I wish to convey.

We may now turn from the consideration of the clock and separate motor meters, and give our attention to what is to-day the most important class of electrical recording instruments, the motor meters, or those whose registering train is actuated by the current to be measured. There are quite a large number of meters of this class, although invention until recently has not been as prolific in this particular direction as in the clock meter field. In the majority of cases, motor meters have been designed for alternating circuits, and these again naturally divide themselves into two classes, those actuated by inductive principles, and those whose motive powers act direct, and which are similar in character to the electric motor. Of the first class there is a large number, designed, of course, for alternating circuits.

These are almost exclusively of two forms—the wound and the unwound armature types. But few, if any, of the former are in practical use, though several have, I believe, shown very fair results. As a rule, they consist of a field formed of a coil or coils in series with the lamps, and a small drum, or other closed circuit armature, preferably without iron, whose commutator is short-circuited across, by directly connected brushes, or other similar means. This meter will record with considerable accuracy, but in the presence of better and simpler plans, it has not met with general favor.

The other class of inductive meters is, in its various forms very familiar to almost every one. It consists, in general, of a coil or coils, in series with the lamps forming the primary. A short-circuited coil of low resistance within and at angle to this, forms the secondary, and within this again is a more or less solid metal armature of disc, drum or other shape, generally wholly or in part of iron, and mounted on a carefully balanced shaft, which, on rotating, actuates the recording dial.

Meters of this construction while highly practical and decidedly useful, are scarcely all that could be desired for several reasons, all of which tend to introduce errors. In the first place their construction and principle prohibit entire accuracy on very low readings. This is quite largely due to the fact that nothing is present to balance friction.

Now the theory of meters as set forth in most of the patents on file, claims a torque proportional to the square of the current, which doubtless would be correct, could we neglect the effect of certain minor influences. In reality, careful tests seem to show that torque falls somewhat below the square, and above the direct proportion, and the proportion does not seem to hold good at various points of load. The speed of motor meters is naturally approximately proportional to the torque, and they therefore tend to run too fast and have to be restrained, which is accomplished in various ways, as we shall presently see, while discussing the question of drag or damping mechanism. None of the inductive meters will run on direct current, of course.

We now come to the second form of motor meters—those which are not dependent upon inductive action for their rotation, and are consequently equally serviceable for alternating or direct circuits. Of these there are but a few, all of them having a field in series with the lamps and an armature—sometimes in series and sometimes in shunt. Of the former kind but few have been tried carefully enough to thoroughly prove their merits.

Perhaps the most successful of these has a heavy iron field, with resultant poles above and below a shallow basin of mercury. The current for the lamps passes through a copper coil around, and excites, the field, thence through the mercury from a portion of its periphery to centre or *vice versa*. This naturally causes the mercury to rotate, its speed being proportional to the amount of current, minus, of course, the effect of friction, the mercury in this case forming the armature. Friction is balanced in this meter quite successfully by the introduction of a fine coil of high resistance around the field. This coil is "in shunt across the line," and serves to intensify the field on the lower readings, while on the higher ones it bears too small a proportion to the total field to exert any appreciable influence. This coil can be nicely adjusted to balance friction, by varying an outside resistance. While such a meter has many weak points, still it has one marked advantage, the balancing of friction. This cannot be given too great importance in motor meters, for friction is their weakest point, and by successfully neutralizing this, they may be brought to almost any degree of accuracy, provided always that their fundamentals remain proportional throughout.

The remaining class of motor meters embraces those with a

---

[1] *Industries.*

series field and shunt armature. These are somewhat of a departure from the others, since they are not current meters, but power or watt-meters. Their construction is in all cases quite similar to an ordinary shunt motor, the conditions of field and armature being reversed. The field is in series with the lamps; the armature, which is of high resistance, and generally of Siemens construction, with a commutator of a few segments, is placed "in shunt across the line," the shunt being taken off beyond the field coils. An outside resistance is placed in this shunt circuit, to reduce the current in the armature to the necessary small quantity and to prevent any appreciable waste across the line.

The strength of armature then, may be seen to be dependent on the pressure, whilst that of the field depends on the expenditure of current. The torque of this meter then, is directly proportional to the power passing, and the speed is naturally proportional to the torque (again minus the friction) but the friction is balanced in these meters, as in the previous one, by the presence of a "shunt field," since the armature circuit is taken off beyond the fields, and consequently passes through them in addition to the current for the lamps. As in the previous meter this serves to counteract the retarding influence of friction in the lower readings where it is dangerous, whilst in the higher ones it bears so small a proportion to the total field as to be inappreciable. This meter is, of course, equally useful without change of calibration on either a direct or an alternating current of any frequency.

Motor meters, as a class, rotate far more rapidly than is allowable in practice. It has been found necessary, therefore, to introduce a "drag," or resistance to rotation, to slow the meter to a reasonable speed. This has been done in several ways; perhaps the most common method being to attach to the shaft a number of air fans. These are quite largely used, and with fair success. The resistance of an air fan to rotation is approximately proportional to the square of the speed. Therefore this device is only fitted for combination with such meters as have a torque increasing with the square of the current. But since the torque of such meters does not quite reach the square, the retarding effect increases rather too rapidly, and has a tendency, though not always pronounced, to cause the speed of the meter to fall off proportionately on high loads. An effort has been made to overcome this disproportion of the fan's resistance by substituting folding fans which close by centrifugal force, on the principle of the steam-engine governor. This novel idea, whilst a decided improvement, scarcely overcomes the difficulty.

Another method of drag, which has been used with some success is the rotation of a small fan in a liquid, a method perhaps rather better than the previous one, since resistance to rotation falls below the square of the speed, when the liquid itself begins to rotate. Much depends in this case on the shape of the receptacle containing the fluid.

A third method, certainly by far the best, consists in rotating a small inefficient dynamo, generally a mere disk, turning between permanent or electromagnets. This resistance is of course directly proportional to the speed, and therefore to the torque, being indeed the machine reversed. By applying this drag, friction is again the only difficulty to contend with.

One other important point in connection with the drag and the friction we must not neglect. The greater the drag (commensurate, of course, with sufficient speed), the smaller the proportion of friction to the total load will be, and the greater the accuracy of the instrument's registration.

To sum up then, it would seem that the most practical and useful meter, according to our present light, would be a motor meter of other than inductive type—preferable an energy rather than a current meter—with some force to balance friction, with a drag which is directly proportional to the speed, and which will be comparatively heavy, making the irregular friction as small a portion of the load as possible. With all these features properly worked out and applied there can be no reason why a meter should not be accurate, efficient, comparatively cheap, and thoroughly able to take care of itself without undue attention.

There is another form of motor meter somewhat akin to the clock meters, which we discussed above. This comprises those instruments whose motor would rotate at a constant speed, provided the resistance to rotation were also constant. In other words, the current passing through the meter would be so arranged as not to cause fluctuations of speed in the motor directly. This is easily accomplished by placing the motor in shunt across the line like a lamp, and properly proportioning its windings. Variation in speed of the motor which is geared directly to the dial, is accomplished in this class of meters by varying the resistance to rotation or drag.

"HEATING AND VENTILATION."

We have received the first number of this new monthly, dated Jan. 15. It is very tastefully printed, and abounds in excellent reading, well illustrated, on the subjects within its province. A large number of advertisers also evince good judgment by patronizing the paper.

SOME OBSERVATIONS UPON THE CONDUCTIVITY OF A COPPER WIRE IN VARIOUS DIELECTRICS.[1]

BY FERNANDO SANFORD, M. S.

The author gives the results of an investigation of the influence upon the electric resistance of a conductor as dependent upon the dielectric surrounding it. For this purpose the investigator employed a cylindrical copper tube 120 centimetres long and 2.5 centimetres in internal diameter. Within this tube which was closed air tight by copper plates, a copper wire one millimetre in diameter was passed lengthwise through the centre. Stop-cocks were provided for filling and emptying the tube of different liquids, gases and vapors. Arrangements had also been provided for measuring the temperature of the tube. The wire was in circuit with a Wheatstone bridge and the current was passed one way through the tube and returned through the wire. In this way the entire field of force of the current was confined within the tube.

Taking the conductivity of the wire in air as unity the conductivity in the liquids examined were as follows:

Petroleum	1.0018
Carbon Bi-Sulphide and Oil of Turpentine	1.0009
Carbon Bi-Sulphide, uncertain, apparently	1 +
Wood Alcohol	.9998
Benzine	.9994
Wood Alcohol and Benzine	.9985
Absolute Alcohol	.9981
Wood Alcohol and Petroleum	.9973
Distilled Water, uncertain, apparently	1.—

Tests made with the tube filled with various gases, gave the following results:

Alcohol Vapor	.99949
Chloroform Vapor	.99830
Gasoline Burning Gas	.99820
Sulphuric Ether Vapor	.99750
Carbon Bi-Sulphide Vapor, approx	1.
Rarefied Air less than	1.

Prof. Sanford points out that the above order corresponds with that of the refractive indices of the respective gases and vapors with the exception of the carbon bi-sulphide vapor; but he points out that no value should be attached to this comparison for the reason that the vapors are mixed with air, and their density was perhaps very different from that at which their refractive indices are determined.

EXPERIMENTS IN ELECTRIC AND MAGNETIC FIELDS, CONSTANT AND VARYING.[2]

At the meeting of the Physical Society, held on November 25, 1892, Professor S. P. Thompson, D.Sc., F.R.S., Vice-President, in the chair, the following communication was made by Messrs. Rimington and Wythe Smith: In the first set of experiments shown, exhausted electrodeless tubes and bulbs were rotated rapidly in a constant electric field between two parallel charged discs. Double fan-shaped images were produced by the tubes, due to the displacement currents which pass to equalize the potentials at the end of the tubes. These fans were not symmetrical with respect to the lines of electric force, but were displaced in the direction of rotation. In explanation of this phenomenon it was pointed out that as a tube rotated, the potential difference between its ends increased until this difference was sufficient to break down the dielectric in the tube. The discharges would, therefore, pass at the ends of the intervals, during which the difference of potential was rising, and consequently the images would be displaced from the symmetrical position in the direction of rotation. The number of discharges produced during one revolution was found to depend on the strength of the electric field, but not on the speed of rotation, and that end of the tube which was approaching the negatively charged plate appeared brightest. These experiments were referred to as examples of the direct conversion of mechanical energy into light.

Instead of rotating tubes in a constant electric field, the tubes were next kept stationary, and a varying electric field produced by connecting the plates with an influence machine allowed to spark; under these conditions the tubes and bulbs were seen to glow.

Using large suspended plates charged by an induction coil, long tubes were caused to glow brightly, even at considerable distances away from the plates. The glow could be apparently wiped out by passing the hand along the tube.

Another series of experiments were performed in varying magnetic fields. With a view to showing Hertzian phenomena to large audiences, the authors tried Geissler tubes to replace the spark-gap in resonators with great success. When large Leyden jar circuits were used, the effects were very brilliant. Another form of resonator consisted of a bent wire terminating in two plates between which an exhausted tube was placed. This tube

---

2. *Engineering.*

became luminous when the resonator was placed in the vicinity of a fairly large Hertz oscillator.

Other experiments similar to those shown before the Society at Cambridge by Professor J. Thomson on discharges in exhausted bulbs were then made, the bulbs being placed with a coil of wire of four turns forming the connection between the outer coatings of two small jars, whilst sparks passed between knobs connected with the inner coatings. The bulbs glowed brightly at each discharge, rings of light being seen near their inner surfaces. On putting a ring tube outside the coil this was also seen to glow. The most brilliant part of the glow always occurred in close proximity to the wire coil.

A secondary coil wound by the side of the above-mentioned primary, could be short-circuited at will; this had the effect of decreasing or extinguishing the luminosity in the bulb or tube. Bright sparks passed between the secondary terminals when held a short distance apart, but the shock experienced by touching the ends was not serious.

The above arrangement, with the addition of two Geissler tubes placed in series between the outer coatings of the jars, was used to illustrate the fact that closing the secondary diminishes the impedance of the primary circuit of a transformer.

Experiments on condensers made of tinfoil on glass were shown. In one of them, parts of the coatings, in the form of letters had been removed, and the spaces became luminous when the condenser was connected with an induction coil. In another experiment a glass plate was moved to and from a condenser, and a musical note could be heard, whose pitch increased as the distance between the glass plates diminished. The note was said to be the octave of an open organ pipe whose length was equal to the distance between the plates.

SECOND CONVENTION OF THE CANADIAN ELECTRICAL ASSOCIATION AT TORONTO, JANUARY 25 AND 26, 1893.

The second convention was opened at the School of Practical Science at 2 p. m., January 25, by President J. J. Wright who delivered his address, in which, after referring to the rapid strides being made in the application of electricity as a motive power for street railways in Canada and to the prosperous condition of the electrical industries, he cautioned the members against being led astray by visionary schemes which were springing up like mushrooms. Their inevitable failure would bring discredit to a certain extent on legitimate enterprise and profitable business. During the half year just passed there had not been many new developments in the application of electricity. Effort appeared to have been directed to perfecting known appliances and inventions, in which much progress had been made, especially in the improvement of street railway apparatus. New departures were noticeable in the engineering branch. The vertical type of large engine had entered the field, and was there to stay. In electric generators, large units were also growing in favor.

He recommended for consideration the appointment of subsections to deal with details that were beyond the scope of the Association as a whole, as, for example, the question of fuel supply. In Ontario and the greater portion of Canada coal has to be imported. United action on the part of the operators of central stations, which would establish direct communication with the miners of coal, might result in a considerable saving in the cost of fuel. Electrical men were also interested in the question of railway charges and it had been suggested that the Association should endeavor to have the classification of electrical apparatus modified so as to reduce the high rates of freight charged on some kinds of electrical material. In conclusion the President commented with satisfaction upon the progress being made in telephony throughout Canada and also referred to the recent developments of scientific research.

Prof. Rosebrugh then addressed the convention, welcoming the members to Toronto on behalf of the School of Practical Science.

Mr. C. H. Mortimer, the secretary-treasurer, next presented his report for the past six months. It showed that the affairs of the Association were in a prosperous condition. The receipts amounted to $468.24 and after paying all expenses there was a balance on hand of $208.18. Since the last convention eleven members had joined the Association, making the total membership 119.

The Committee on Statistics, which had been appointed at the last convention to collect statistics of the electrical industries, asked for a grant of money to print sets of questions to be submitted to the telephone, telegraph and electric light and power companies. From the answers to these questions, statistics would be tabulated. The authority for a grant was given.

The first paper was by Mr. Geo. Black on "Electrical Measurement" and led to considerable discussion on the part of the members.

Mr. W. A. Tower then read a paper on "Underground Construction" in which he referred to what was being done in that line by the Bell Telephone Company in Toronto.

Mr. A. B. Smith, of the Great North-Western Telegraph Company, explained the use of motor generators by his company in place of chemical batteries.

After the close of the session, a number of the members visited, by invitation, the laboratories of the School of Practical Science, the station of the Toronto Incandescent Electric Light Company and that of the Toronto Electric Light Company. The evening was spent most enjoyably at an informal dinner given the members by the president and officers of the Association.

At the morning session, on Thursday, in the absence of the author, Mr. A. B. Smith read the paper of Mr. J. M. Campbell on "Free Wiring" in which the free wiring of premises for customers by electric light companies was strongly opposed.

Mr. R. G. Black then read an instructive paper on "The Incandescent Lamp."

The remainder of the morning session was devoted to the consideration of the proposition to divide the Association into sections representing the different branches of electrical industry. Those in favor of the change contended that by division into electric light, telephone and other sections, a much greater field would be covered in the same time and the interests of these different departments advanced. The majority of the members held, however, that such a division would not be conducive to the interests of the Association as a whole and it was decided to make no change for the present.

Upon re-assembling in the afternoon, Prof. Rosebrugh read a paper on "Speed Control" treating of the different methods of speed regulation and their advantages and disadvantages.

After, this Mr. E. C. Breithaupt read a paper on "The Probabilities as to the Success of the Distribution of Power at Considerable Distances by High-Tension Currents."

Before adjournment, it was decided to hold the following convention at Toronto during the month of September, next, the exact date to be fixed by the executive. A vote of thanks was passed to the Acting Minister of Education and the Faculty of the School of Applied Science for the use of the room in which the meetings were held. This brought to a close the second convention of the Association, which it was felt by all had been a most successful one as shown by the interest manifested in the different papers and the discussion they provoked.

After adjournment, the members visited the new Exchange of the Bell Telephone, Co., one of the finest on this continent, by invitation of that company.

Among the members in attendance were the following: J. J. Wright, Toronto; John Carroll, Montreal; C. H. Mortimer, Toronto; D. A. Starr, Montreal; H. O. Fisk, Peterboro; A. B. Smith, Toronto; D. Thomson, Hamilton; John Yule, Guelph; Thomas H. Wadland, Hamilton; L. B. McFarlane, Montreal; A. M. Wickens, Toronto; George Black, Hamilton; J. A. Baylis, Toronto; W. A. Tower, Toronto; R. G. Black, Hamilton; A. T. Smith, Kingston; B. J. Throop, Brantford; George M. Wright, Montreal; J. H. Greer, Peterboro; H. Beaumont, Toronto; J. W. Taylor, Peterboro; J. A. Kammerer, Montreal; George W. Sadler, Montreal; O. C. Armstrong, Toronto; W. Bourne, Toronto; H. S. Thornbury, Toronto; A. C. McCallum, Peterboro; W. J. Jones, Toronto; Hugh Neilson, Toronto; W. B. Evans, Toronto; W. J. Clarke, Toronto; R. F. Carter, Niagara Falls; Chas. B. Hunt, London; Alex. Stark, Toronto: John Langton, Peterboro; E. C. Breithaupt, Berlin; James P. McQuaide, National Conduit Company, New York; W. R. McLaughlin, New York,

PREPARATIONS AT ST. LOUIS FOR THE ELECTRIC LIGHT CONVENTION.

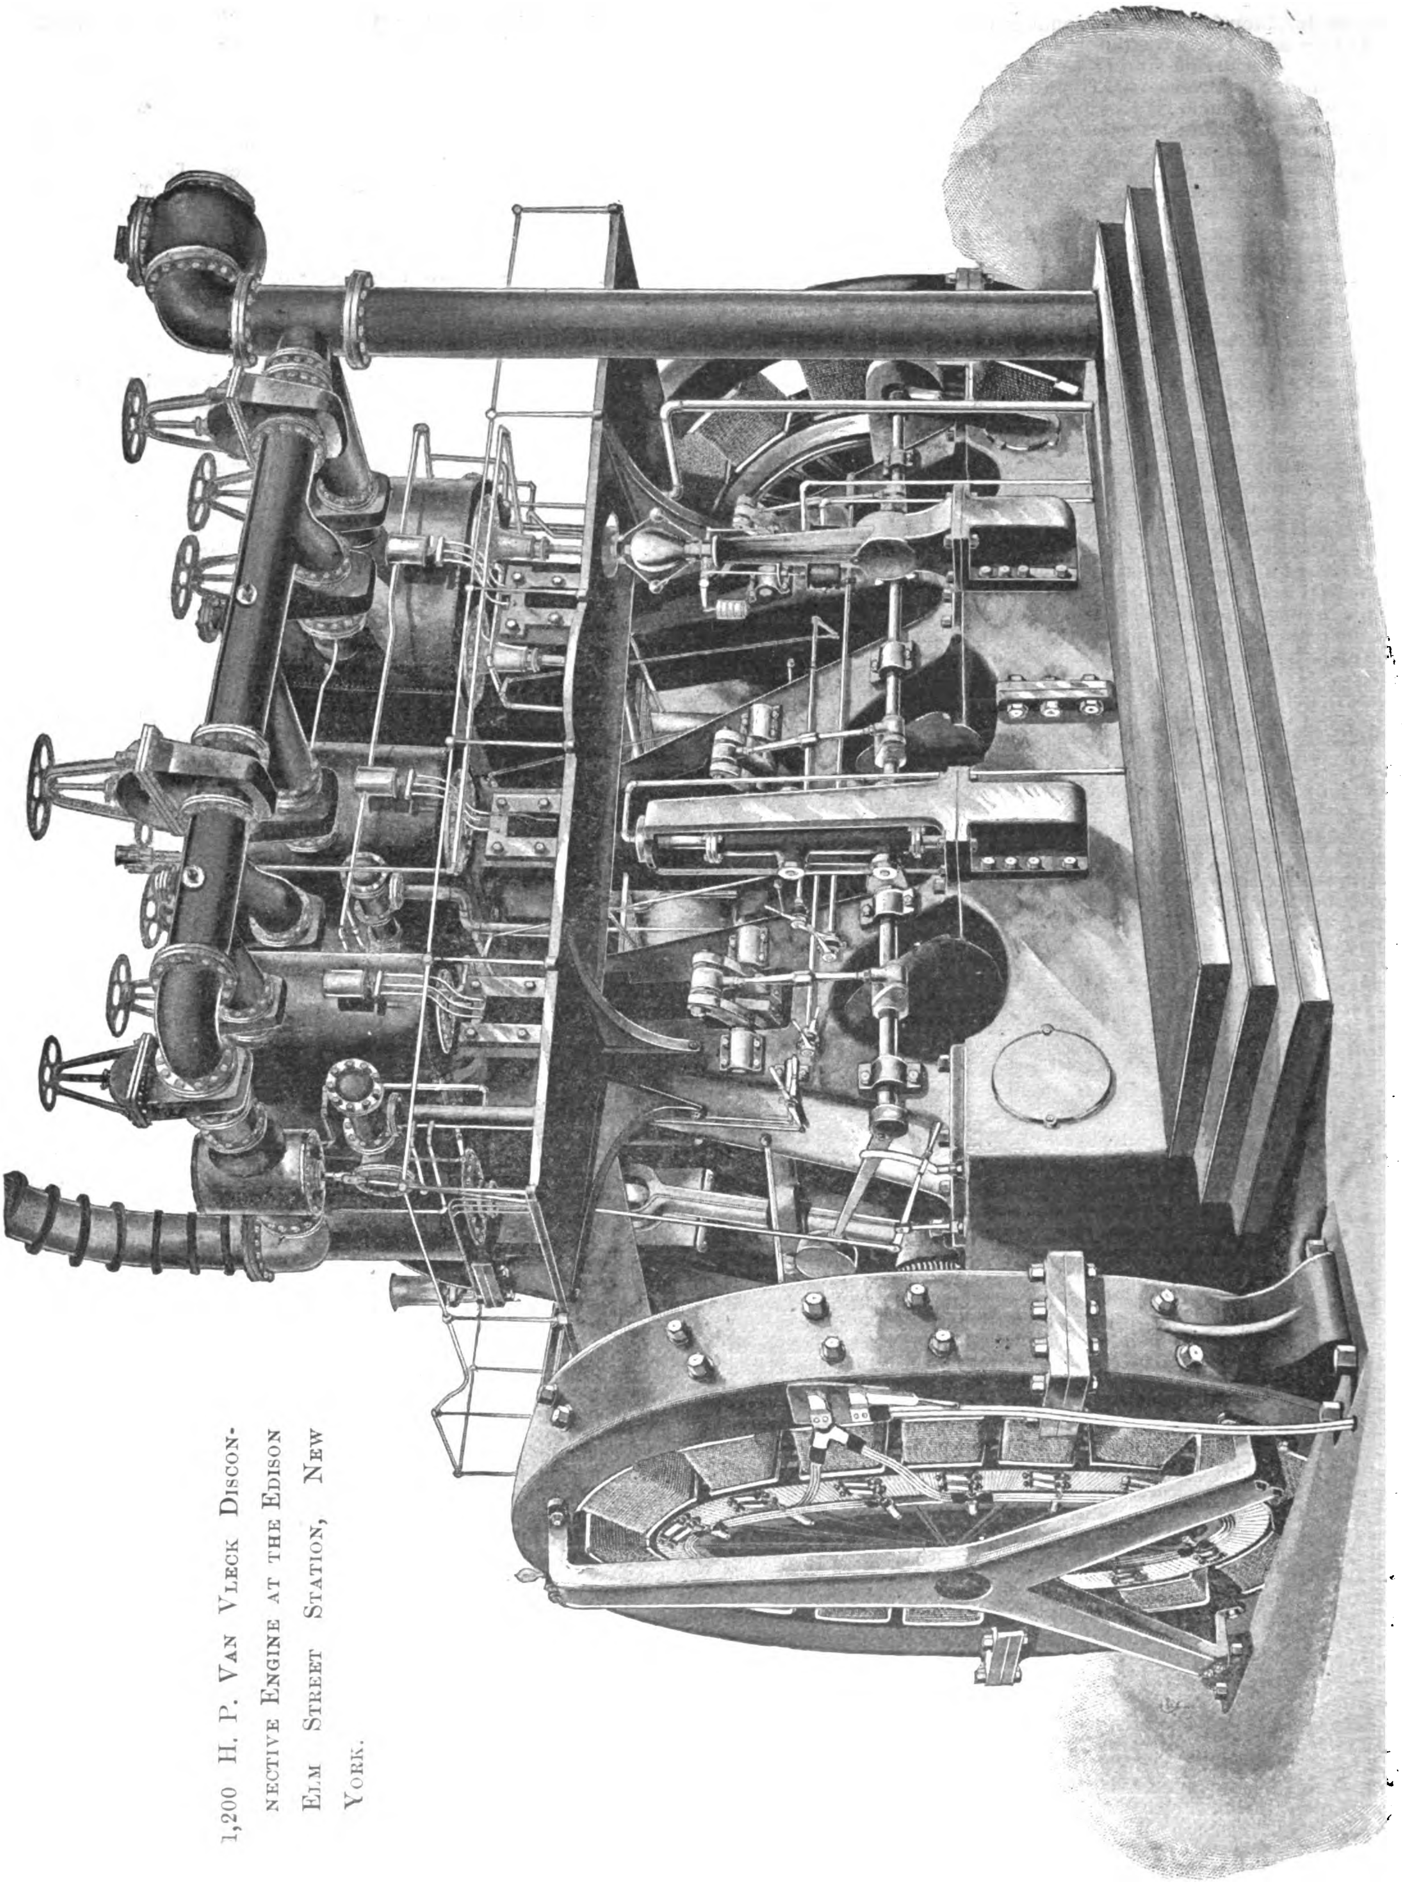
At a recent meeting of the St. Louis Electric Club, as mentioned in our columns last week, the question of entertainment for the National Electric Light Association was discussed. It was the general opinion of those present that no effort or money should be spared to make the event a memorable one and to entertain the 300 visitors expected in a royal manner.

Mr. J. A. J. Shultz was appointed chairman of the finance committee, and with him were associated James I. Ayer, E. D. W. Meier, Geo. P. Jones, T. M. Ambler, Louis Nahm, C. R. Scudder, Robert B. Annan, Marcus Bernheimer, John S. Moffitt, Frank R. O'Neill, F. J. Wade, L. D. Kingsland, Frank Shapleigh, Frank Gaiennie, Goodman King, Ben. Elseman, Douglas Cook, Ellis Wainwright, A. Siegel, S. G. Booker, John C. Wilkinson.

The executive committee was named as follows: Mr. Nahm, chairman; James I. Ayer, Frank Gaiennie, Nathan Frank and Goodman King.

COLD IRONY.

An Ottawa electrician claims to have discovered a process for utilizing electricity to abstract the heat from cast iron blocks until they are reduced to the temperature of ice, and then using them as a substitute for natural ice. He claims that this can be done at a price to compare favorably with the latter.



1,200 H. P. Van Vleck Disconnective Engine at the Edison Elm Street Station, New York.

1200 H. P. VAN VLECK DISCONNECTIVE ENGINE AT THE EDISON ELM STREET STATION, NEW YORK.

THE accompanying engraving represents the first of a pair of large engines which have been constructed for the Edison Electric Illuminating Company, of New York, by the Dickson Manufacturing Company, of Scranton, Pa. This engine is now completely erected and in running order at the Edison Elm street station, and is directly connected to multipolar dynamos. It is of the same type as the smaller triple engines which have been built for the company, and are now operating in the Twenty-sixth street station, and was designed from the specifications of Mr. John Van Vleck, with the assistance of Mr. J. W. Sargent. Valuable suggestions having been received from Mr. S. F. Prest, of London, England.

The engine is intended to develop 1,250 h. p. when running at best economy, although it can easily develop 1,500 h. p., should the occasion require it. The cylinders are 24, 35 and 52 inches in diameter, with a 36 inch stroke and speed of 100 revolutions per minute The shaft is of wrought iron and is 12 inches in diameter and is made in three sections in which the coupling forms a part of the crank blocks, thus saving the space ordinarily utilized by shaft couplings—a detail which has been very successfully applied by Mr. David Joy of England.

The steam chests are placed at the front of the cylinders, instead of between them, as is the common practice, and in this way as much as 30 per cent. of floor space is saved, which is a very important consideration where real estate is valuable. The engine is therefore only 19 feet 6 inches long over end bearings and is 12 feet wide at the base.

The piston heads and cylinder covers are of cast steel of the marine "coned" type, which not only makes these parts extra light and strong, but economizes in the height of the engine; it being only 19 feet 6 inches in extreme height from the bottom of the base.

The placing of the steam chests on the engine front, lends itself admirably to the employment of a system of disconnective piping, which makes it practicable to run the engine with any of its cylinders thrown out of gear, should any part of the engine need repair. The engine is therefore called a disconnective engine, to distinguish it from other types of multi-expansion engines, which would have to shut down completely should an accident happen to any cylinder or valve gear. The conditions under which an electric generating engine has to work are even more severe than in the case of marine engines, which usually have long intervals for making repairs in port; while an electrical generating engine, in a city like New York, has to run nearly all the time, so that a disconnective engine is considered to be a vital necessity for land work of this character.

The 1,250 h. p. engines will form a pair of the smaller engines for the Elm street station, as the regular unit will be a quadruple expansion engine of 2,500 h. p., to be built somewhat on the same plan as the smaller engines, with the important difference, that they are to be constructed on the two-crank tandem type instead of on the three-crank type as illustrated.

All the engines for the Elm street station are to be built for 210 pounds steam pressure and are to be amply strong to carry even higher pressure if necessary. The building of the two-crank quadruple engine enables the company to place twice as much generating capacity within the same area as could be obtained by employing three-crank triple-engines, which is a most desirable thing to do from a financial point of view. We are indepted to *Power* for the excellent illustration on the opposite page.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 24, 1893.

Alarms and Signals :—

Electric Annunciator System, H. Van Hoevenbergh, New York, 490,327. Filed Mar. 24, 1892.

A visual annunciator in which electric lamps are employed to illuminate transparent numbers, letters and the like.

Electric Show Case Alarm, R. C. Kruschke, Duluth, Minn., 490,479. Filed July 9, 1892.

Railway Signal, I. L. Green, Kittanning, Pa., 429,626. Filed Jan. 9, 1892.

An electrically operated block signal.

Conductors, Conduits, and Insulators :—

Insulator, L. McCarthy, Boston, Mass., 490,302. Filed July 8, 1892.

Invention consists in replacing a portion of the sheet mica with flake mica pressed and compacted around the connecting piece.

Closed Conduits for Electric Railways, R. Parker & B. F. Sutton, Brooklyn, N. Y., 490,306. Filed Jan. 9, 1892.

Employs a flexible insulating tube, a main conductor within it, an interrupted conductor fixed to the tube opposite the main conductor, and combined clamping and supporting plates having jaws which partly embrace the main conductor exterior to the insulated tube.

Insulator, A. J. Hauty, Saltsburg, Pa., 490,560. Filed Aug. 29, 1892.

Employs an outer cap which screws down over the line-wire, holding it firmly in place without the necessity for tie wires.

Electric Conduit, E. L. Ransome, Oakland, Cal., 490,630. Filed Apr. 5, 1892.

A water conduit having passages for electric conduits formed within its walls in combination with a manhole and entrance chamber common to all.

Dynamos and Motors :—

Electric Motor, J. W. Hansen, St. Paul, Minn., 490,280. Filed Sept. 25, 1891.

Employs laterally adjustable stationary field magnets and a double concentric commutator, and adjustable commutator brushes mounted in one of the frame plates and making contact with the different faces of the commutator.

Armature for Dynamo Electric Machines or Motors, E. Thomson, Swampscott, Mass., 490,376. Filed July 10, 1891.

Employs a sectional laminated core having overlapping sections, holes through said sections near their inner edges, and binding rods occupying the holes.

Dynamo Electric Machine, R. Lundell, Brooklyn, N. Y., 490,449. Filed June 21, 1892.

Employs a single field magnet coil surrounding inwardly projecting poles, and a rotary armature whose axis is parallel with that of the field magnet coil.

Dynamo Electric Machine, C. Wachtel, Newark, N. J., 490,460. Filed June 13, 1892.

Employs a commutator consisting of porcelain sections having longitudinal slots, each section having an annular portion and an under-cut portion with insulated commutated sections between the annular portions.

Lamps and Appurtenances:—

Electric Lamp Socket and Tap. A. F. Vetter, New York, 490,605. Filed May 20, 1892.

Measurement :—

Electric Meter, O. Frölich, Berlin, Germany, 490,279. Filed Nov. 16, 1892.

An electric meter in which the counter registers the number of oscillations of a bar of soft iron subject to the influence of the current.

Miscellaneous :—

Locking Hat Rack, F. B. Trout, Detroit, Mich., 490,326. Filed June 13, 1892.

Electric Mat, W. G. James, Harlem, Ill., 490,353. Filed Sept. 29, 1892.

Electrical Musical Instrument, A. Montamellin, Portland, Ore., 490,358. Filed May 31, 1892.

Fountain, G. Trouvé, Paris, France, 490,378. Filed Sept. 30, 1891.

An electric illuminated fountain.

Support for Telegraph Cables, F. Le B. Bedwell, London, England, 490,584. Filed Sept. 26, 1891.

Apparatus for Distributing Mail, F. D'A Goold, New York, 490,607. Filed May 6, 1892.

Employs a driveway and a carriage movable along it containing articles in separate packages, and magnetic releasing devices by means of which the packages are dropped off at predetermined points.

Railways and Appliances :—

Electric Railway Conductor, H. A. Miner, New York, 490,297. Filed June 2, 1892.

Employs a feed wire suspended in contact with the trolley wire and serving both as a support and an electrical feeder for the latter, in combination with a case partly inclosing both wires.

Electric Locomotive, A. Philipsborn and M. Schiemann, Berlin, Germany, 490,307. Filed April 14, 1892.

Employs a motor movable relatively through the traction wheels and means for frictionally transmitting power from the motor to the wheel.

Elevated Railway System, C. Drill and H. J. Hutchinson, St. Louis, Mo., 490,549. Filed Feb. 18, 1892.

Claim 1 follows:

An electric air ship consisting of a carriage provided with a motor or motors, a balloon movable laterally independent of said carriage and connected therewith by a single flexible cable, and a car carried by the balloon and independent of the track along which the motor travels.

Conductor System for Electric Railways, R. Hayden, Fairmond, W. V., 490,597. Filed April 13, 1892.

Employs an insulated conductor, a contact conductor divided at intervals into sections normally disconnected from the insulated conductor and from each other, and means by which, at the time when the current collector passes off of a section preceding a given section, and on to the latter, the preceding section is disconnected from the insulated conductor and a succeeding section connected therewith.

Switches and Cut-Outs :—

Cut-Out for Electric Circuits, M. Leavy, Pittsfield, Mass., 490,292. Filed June 16, 1892.

Employs fuse strips enclosed in separate tubular cases readily insertible in the porcelain box without the use of tools.

Electric Switch, A. L. Rohrer, Lynn., Mass., 490,363. Filed March 17, 1892.

Employs switch arms each carrying one of the contacts and mechanically connected to the contact with a rotating supporting plate to which both arms are pivoted on a common axis.

Electrical Connecting Device, J. Hutchinson, New York, 490,477. Filed Sept. 16, 1892.

A combined safety cap and switch especially adapted for use on connecting blocks.

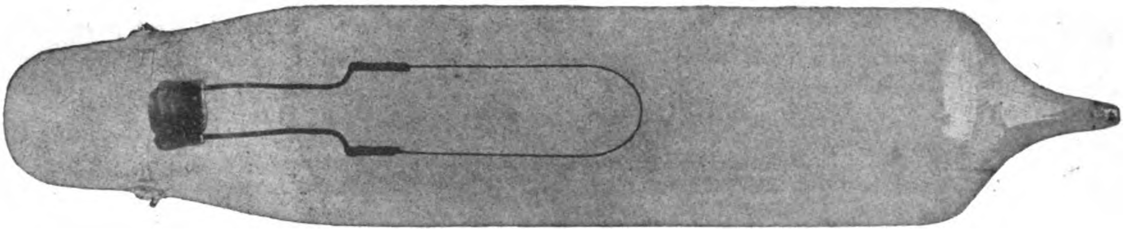
COLLEGE NOTES.

ELECTRICAL ENGINEERING AT COLUMBIA COLLEGE.

RECOGNIZING the increasing importance of the course of electrical engineering established at Columbia College in 1888, the trustees at a recent meeting decided to create an entirely independent department devoted to this branch of engineering. It is intended to still further increase the scope and facilities of this department, and thus to offer students a thoroughly comprehensive course of study. We are also gratified to learn that Prof. F. B. Crocker, whose conscientious work has contributed so much to the success of the electrical engineering course at Columbia, has been promoted to a full professorship, with charge of the new department.

CHAS. D. JENNEY, president of the Jenney Motor Company, of Indianapolis, was a recent Chicago visitor and called at the ELECTRICAL ENGINEER'S western office.

GOEBEL'S INCANDESCENT LAMP AND FILAMENT PLANER.



Alleged Goebel Carbon Filament Lamp, Said to Have Been Made Prior to 1872.

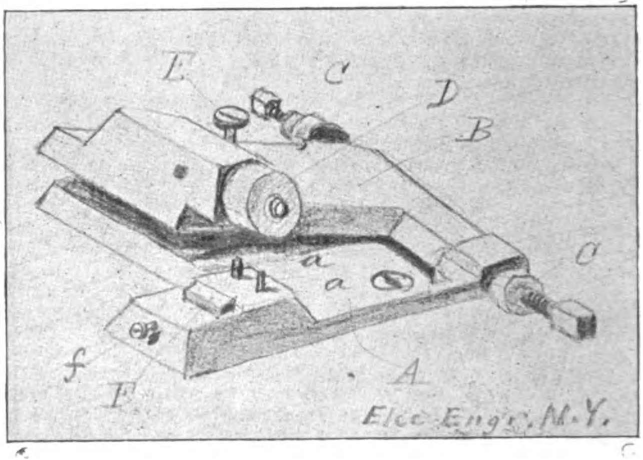
The accompanying illustration is made direct from a full-sized photograph of an incandescent lamp which has figured largely in the supplementary legal proceedings in reference to the motion for an injunction against the Beacon Company of Boston asked for by the Edison Company, which is now pending before Judge Colt. This lamp was first introduced as an exhibit by the attorney of the Beacon Company at the second hearing on February 1, and is claimed in the accompanying affidavit of the Goebels, father and son (abstracts of which are printed elsewhere) to have been made by the elder Goebel prior to 1872, and on the other hand, was denounced by the attorney of the Edison Company as a manifestly fraudulent exhibit, manufactured for the purposes of the pending case, and that within the past six months. The results of its examination by the defendant's experts will be found in brief in the affidavits of Messrs. Pope and Vandergrift, in which, as in other affidavits, it is referred to as the "Goebel lamp, No. 4." The decision in the pending proceeding, if not the ultimate fate of the Edison patent, cannot but turn largely upon the genuineness of this exhibit, or more properly upon the credibility of the witnesses by whose testimony its genuineness is sought to be established. Of the nature of this evidence, and of the credence which ought to be given to it, the abstracts of the more important affidavits pro and con, given elsewhere, will perhaps assist the reader in deciding for himself.

The lamp in question has a thin carbonized filament of bamboo of horseshoe shape, and has small flat platinum leading-in wires, sealed by fusion into an exhausted glass globe, and the whole structure in fact must be admitted to be, to all intents and purposes, identical with the commercial incandescent lamp of the present day.

Portrait of Goebel from an Old Daguerreotype.

In the accompanying engraving we show also Goebel's little bamboo filament planer. A represents the iron base; B the hinged clamping jaw; C and D, respectively, the set screw, and roller pivoted to the clamping jaw; E, the set screw for adjusting the distance of the roller D from the bed A when B is held down; F the vertical blade of the plane, beveled like a chisel; *f*, a set screw for holding F in position; *a a*, guide pins for holding the filament while being planed. The set screw E adjusts the roller D for any thickness of carbon.

We present also a portrait of Goebel made directly from an old photograph taken at the time when his story shows him to have been interested in early work on incandescent lamps, and to have made the lamps upon which the present defence is based.



Goebel's Filament Planer.

LITERATURE.

Dynamometers and Measurement of Power. By John J. Flather, Ph. B., M. M. E. *New York*, John Wiley & Sons, 1892. 215 pp. 5 by 7½. Price $2.00.

In this age of innumerable applications of power a work treating of the methods of measuring it, must be of value to all engineers. The electrical engineer, especially, is frequently called upon to estimate the quantity of power required in the operation of the endless variety of machinery which the electric motor is now called upon to drive, and he will find in the work before us a most concise and accurate guide.

The author describes all the more general forms of dynamometers including friction brakes, absorption and transmission dynamometers, and devotes attention to the power required to drive lathes and other machinery. The chapter on the measurement of water power will also prove useful to many. The book is well illustrated throughout, and the subject treated from a thoroughly practical stand-point.

Hilfsbuch fuer die Elektrotechnik. 3d. Edition. By C. Grawinkel and K. Strecker. *Berlin*, Julius Springer, 1893. 642 pp. 5 by 8. Price $4.80.

This excellent work of reference has been thoroughly revised and brought down to date. Among the new material in this edition we notice a chapter on "Magnetic Measurement," the "Polyphase System of Distribution," and the "Employment of Induction Coils and Condensers in Alternate Current Circuits." The parts devoted to systems of distribution and dynamos are especially worthy of mention, and the details of the construction of German machines, both continuous and alternating, will be of special value to the designer of dynamo machines.

LEGAL NOTES.

INCANDESCENT LAMP LITIGATION.

THE GOEBEL DEFENCE.—EDISON ELECTRIC LIGHT COMPANY (GENERAL ELECTRIC COMPANY) *vs.* BEACON VACUUM PUMP AND ELECTRICAL COMPANY IN U. S. CIRCUIT COURT, BOSTON, FEB. 1 AND 2, 1893.

The hearing in the case of the Edison Electric Light Co. vs. the Beacon Vacuum Pump and Electrical Co. was continued on Wednesday, February 1st, in Boston, before Judge Colt.

Mr. Wm. C. Witter, for the defendants, filed a printed brief, and asked leave to introduce certain exhibits and affidavits, in the nature of new evidence which could not be presented at the former hearing by reason of the short time allowed for preparation. The exhibits consisted of an incandescent lamp made by Goebel prior to 1872, having a horseshoe filament of carbonized bamboo, in an all glass globe and having platinum leading-in wires; also three old machines made by Goebel for shaping carbons, one of which has been used until quite recently in the Perkins lamp factory. Among the affidavits were several as to Goebel's good character; an expert affidavit from Mr. Pope explaning why this lamp was not permitted to be put in at the first hearing, and also stating that the exhibit lamp still held its vacuum, and a large number of affidavits confirmatory of those heretofore presented, and giving additional testimony to the public use of these lamps by Goebel. Mr. Witter said that the utmost possible diligence had been used in getting this material together, but that it had not been possible to do it in time for the former hearing, and therefore they had put in what they had.

Mr. Fred. P. Fish, for the complainants, urged that the court should either grant or refuse the injunction asked for, upon the affidavits and exhibits heretofore presented. He asserted emphatically that the defence which had been set up was absolutely fraudulent; a more bare-faced fraud even, than the Drawbaugh defence in the telephone litigation. The complainants had a large number of affidavits which would substantiate what he had said. The exhibit now presented was a lamp which a mere inspection was sufficient to show had been made within the past six months for the purposes of this case. He had understood that the case had been closed, and he objected to the admission of any more exhibits and affidavits of the same character.

The Court said that he was disposed to admit the papers and exhibits now offered by the defendant, and to consider them as if they had been part of the evidence originally offered, and to take such action as the record thus before him would justify. Unless complainants counsel entered a formal protest, this course would be pursued. The Court recognized that it was its duty to act speedily in the matter.

In reply to questions by counsel on both sides, the court observed, that after accepting the affidavits and exhibits now offered, and such additional matter as either side might offer during the day, if it were found that the new matter thus presented was controlling as to the decision, then it would be the duty of the court to hear the complainant in reply. The court realized the brief time within which the defendants had been required to prepare their case, but would consider the case closed to-day. If on examination of the record, the case was found to turn on the new matter, the court would hear arguments, and would allow both sides a reasonable time in which to file affidavits in reply and in rebuttal.

Mr. Fish said that he regretted his honor's decision, but should file a number of affidavits in reply to those heretofore presented by defendants.

The Court, on Thursday morning, took the papers and exhibits and reserved decision.

Following are abstracts of the principal additional affidavits filed by defendant.

Henry Goebel (second affidavit) says that before he removed from Monroe street in 1872 had settled upon bamboo as the best material for carbons and always used it thereafter; had then made four instruments for dressing thin threads of bamboo; found one of these at Jan. 26, 1893, and gave it to defendant's counsel (a drawing of this is given elsewhere); sold three of these instruments to C. G. Perkins about 1886; two of these now handed deponent by Mr. Perkins, are the same; one of these was made in the early sixties; by this could make strips thinner and more even than is possible by hand; pulled the strips through the instrument with pincers; had gas in his house before 1872, and had glass blowing machine and had become quite expert in the art; made hundreds of barometers and thermometers, as well as Geissler tubes, and the like. Knew that platinum was best material for leading-in wires, and almost always used it; lamp marked No. 4 (illustrated in another column) has been in deponent's possession since before 1872; has burned it a great many times; it gave a good light; made in Monroe street and afterwards a good many lamps like No. 4 except the glass work was not so well finished. Deponent told Mr. Pope he was mistaken in supposing this lamp could not have been exhausted by the Torricellian process because no traces of mercury appeared upon the interior wires; always used distilled mercury in a very dry atmosphere, which will not adhere to copper. Used a mercury-pump with stop-cocks before 1872, but did not get any better results than by the Torrecellian process. Deponent's lamps were fit for commercial use, but commerce was not ready for the lamps, because there was then no available source of cheap electricity. One of deponents earliest efforts to make a lamp was by using platinum wire as an incandescent conductor; it was two or three inches long and very fine; used it with a vacuum and copper wires sealed in the glass; it gave a good light for a few minutes and then melted and broke the glass; then tried carbon which deponent knew from experience with arc-lamps would not melt. More interest in deponent's work was shown by neighbors and friends while he lived in Monroe street than afterwards when he lived in Grand street; electrical apparatus had become less of a novelty. Deponent has received no valuable consideration for anything he has done for the defendants in this case and does not expect nor desire any; has given his evidence with reluctance and only after urging; has no interest in the result of the suit has no enmity towards Mr. Edison nor desire to injure him in any way; does not know any person connected with the defendant company. When deponent lived in Grand street made a glass fountain and exhibited it for a long time in the show window; it was a difficult piece of glass work, and numbers of glass-blowers used to stop and inquire about it; lighted up his shop in 1882 with a dynamo machine and lamps which had been on hand for a number of years; a partially correct notice of this exhibition appeared in the New York *World* of May 1, 1882. (This notice was reprinted in The Electrical Engineer, of last week, on p. 121.)

Henry Goebel, Jr., makes affidavit that the lamps with iron and copper leading-in wires were among the very earliest his father made; some of these were successful; the great majority of lamps made before 1872 had platinum wires; lamp marked "Goebel No. 4" is an original lamp and has been in their possession since before 1872; it has been kept as a sort of specimen because the glass-work was so good; have both been ready to identify it at any time if called upon to do so; but understood the lamp was under examination by the experts; could identify this lamp by its excellent workmanship and peculiar shape and appearance, even if it had been in the possession of others.

James A. Vandergrift, has examined lamp No. 4; there is a fair vacuum in it and thinks lamp would burn from 100 to 200 hours, which was a good length of life for a commercial lamp in 1880; the filament is, of course, bamboo carbonized, has been burned and is slightly oxydized upon its surface; the circuit is broken but the break does not appear to be in the carbon; sees no reason why the lamp might not have been made in 1872 or earlier.

Franklin L. Pope stated that he at first entertained doubts as to the date of lamp No. 4, because he thought if the lamp had been filled with mercury and exhausted in the manner claimed to have been practiced by Goebel, some traces of that metal would have been visible on the copper wires. Goebel had asserted that if distilled mercury were used, this effect would not take place; tested the matter experimentally on January 26 and found Goebel's assertion to be true. Remembers Geissler tubes were sold by Ritchie in Boston at least as early as 1868; some of these had platinum wires sealed into the side of the exhausted glass tube like those in Goebel's lamp No. 4; estimates No. 4 with unbroken carbon and proper current would give a light of 10 candle-power; such current was obtained in 1872 by the means said to have been used by Goebel; no apparent reason why the lamp No. 4 might not have been made prior to 1872; Goebel lamp No. 4 embodies the second claim of Edison patent in suit; has all the elements, combined and operating as therein set forth.

Prof. Charles R. Cross has examined Goebel's hair pin lamp No. 4; it embodies the invention set forth in the second claim of the Edison patent; has read affidavit of Goebel; there is nothing in appearance of lamp inconsistent with the assumption that they were manufactured as described by him, either by the use of the Torricellian vacuum or by the mercury pump; the Torricellian process would give a sufficient vacuum for a practical incandescent lamp; moreover the mercury pump was well-known in the art at the time the Goebel lamps are stated to have been made; it was pointed out by Faraday half a century ago that platinum is the best material for purpose of sealing a conducting wire into glass; it would have required no invention to substitute platinum for iron leading-in wires at the earliest date mentioned by Mr. Goebel; believes it would be practicable to make an incandescent lamp with iron leading-in wires which should have a life of a considerable number of hours; can discover nothing in the construction of any of the Goebel lamps which would make it improbable that they were constructed at the dates assigned by Goebel. In at least two important particulars the Goebel lamps are superior to the lamp specifically described in the patent in suit; carbonized bamboo is far superior to the tar putty and other filaments specifically set forth in the patent; and the carbonization of the filament while attached to the wires as contemplated in the patent, increases the liability of the occurrence of a bad joint; in the

Goebel lamp the attachment has been made subsequently to the carbonization.

EDWARD E. CARY disposes that he is superintendent of the defendant company; is thoroughly skilled in the manufacture of electric incandescent lamps; has considered the statement made by Professor Thomson and two others in this case that lamps with iron or copper leading-in wires are incapable of practical use. Deponent has known for several years that it is possible to make practical and operative incandescent lamps with iron wires sealed into the glass, but that much greater care is necessary to be exercised in sealing the lamps, and the percentage of unsuccessful sealing is much greater than with platinum. Deponent presents two lamps made within the past two days with iron leading-in wires, one being a glass tube with "meat saw" carbon, and the other a pear-shaped chamber with a "hairpin" carbon. The tube lamp has the pinched seal of the Goebel exhibit lamps No. 1, 2 and 3, the other has the ordinary commercial sealing. The first lamp has been burned eleven hours in the aggregate at full candle-power, at four different times, the lamp becoming cold during the intervals; the seal remains perfect, as deponent has found by testing the lamp for vacuum; the length of life will now be determined by the filament alone; the second lamp has been burned in the same way an aggregate of thirteen hours; it gave 16 c. p., and was cooled five times during the test; this lamp also tests for vacuum and shows no leakage; has used them as long as there was time to do so after making them.

CHARLES G. PERKINS deposes that he became acquainted with Goebel in 1880; was then engaged in making incandescent lamps, and was on the look-out for any information or assistance that would be of value; one of his employees told him he had seen incandescent lamps in Goebel's place in Grand street; went and introduced himself to him (Goebel) and asked to see the lamps he had made; this was about September, 1880; Goebel then showed deponent three or four lamps, some in shape of a tube and others with pear-shaped globes; they had very small carbon burners, and some of them had platinum leading-in wires; one had a straight carbon and the others looped carbons like those made to-day: have examined photograph of lamp No. 3, the lamp with straight carbon deponent saw at Goebel's shop in 1880 was just like it; Goebel said he had made such lamps for years and years; deponents thinks he said 20 years; deponent was astonished at the amount of his knowledge of the subject. Deponent told Goebel he had trouble with the lamps cracking; he replied that if the carbon were made small and of high resistance the leading-in wires could be made small and the liability to crack reduced. Goebel said that platinum was the best metal for leading-in wires; he gave deponent some bamboo to make carbons of and deponent made some of small cross-section as Goebel had told him to do and was very much pleased with the result; Goebel showed deponent a glass mercury pump for exhausting lamps, and told deponent how to carbonize filaments; deponent made six lamps which were tested at 120 Broadway with good results; deponent called upon Goebel frequently in 1880 and 1881; remembers seeing planers that he used in shaping his filaments; bought three of these planers from him about 1886 and still has one of them; saw Goebel blow glass at different times; he was a skilful glass-worker.

DAVID A. HALL, deposes that he resides in Newark, N. J., and prior to 1872 was a manufacturer of jewelry; became acquainted with Goebel by selling him goods; sold him goods until 1886; he was a very ingenious man, very fond of explaining his inventions to every one interested in them; very soon after deponent first became acquainted with him, saw some incandescent lamps he said he had made; they consisted of a glass tube several inches long with wires running through the glass; inside the glass the wires supported a part that lighted up; have examined the four exhibit lamps; the ones he saw at Goebel's were just like them; some had straight burners and some had hairpin shaped burners; deponent saw lamps like the exhibits prior to May 1872; deponent is positive of this date because Goebel gave him a lamp like Goebel hairpin lamp No. 4, as a keepsake; took this lamp home and showed it to his father who then lived next door: remembers his wondering what it was; deponent's father died in May 1873; deponent kept this lamp for many years; may very likely have it yet; have often seen his store in Grand street lit up with his incandescent lamps; they gave a very good light, as good as a gas jet; Mr Goebel is a man of the highest reputation for honesty and veracity, would place the utmost confidence in any statement he might make; have seen him cutting bamboo into strips; he used tools for the purpose; the wires which ran through the lamps were platinum; he gave deponent a reason at that time for using platinum; don't remember the reason he gave, except that platinum and glass were affected alike by the heat; remember Goebel using the ordinary jeweller's draw-plate to make his carbons; these draw-plates had holes of different sizes.

Affidavits were submitted from a considerable number of citizens to the good character, veracity and integrity of Mr. Goebel. Among these are Theron S. Copeland, police captain; William Newman and Edward J. Hogan, practicing physicians, and Henry Grinnell, a large dealer in jewelry, and others.

AUGUST F. HEGER, deposes that he is a glass-blower; commenced work for the American Electric Light Company early in May, 1881, worked at glass-blowing, sealing lamps and the like; the company had trouble in getting good carbons. Because of this trouble the company hired Goebel to make carbons for a considerable time at his store in Grand street; worked frequently at Goebel's place in Grand street sealing into lamps the carbons which Goebel had made; he was very skilful in making carbons; he did glass-blowing very well; Goebel had a mercury pump; he showed deponent how to make these pumps and deponent made several of them afterwards, which were used for exhausting lamps; Goebel on one occasion showed me some old lamps that he kept in the safe; the lamps were like the one in the photograph now shown. (Mr. Witter filed 31 in all of these additional affidavits.)

THE following are abstracts of affidavits presented by Mr. Fish on behalf of complainant:

WILLIAM C. DREYER says that in the spring of 1882, he undertook to form a company to purchase Goebel's invention; saw him repeatedly at that time; about April, 1882, he procured an option from Goebel for $500 to acquire all his inventions in electric lighting; he was to have a large compensation if undertaking was successful; the only inventions he had applied for patents for were the mercury pump and a spiral carbon-holder for incandescent lamps; he said he had made small incandescent lamps, which he described as "fiddle-bow" lamps several years before; spoke to him repeatedly of the importance of his finding one of those lamps; it was a great disappointment that he did not do it; got him to extend the option another three months for $425. His failure to produce any old lamp, his general unreliability of memory and freedom and looseness of statement caused deponent to distrust him, and at the expiration of the option, the whole matter was dropped and deponent lost his investment of $925. If Goebel had then had any lamps made in bygone years, deponent is certain he would have produced them; it was the vital point of the whole matter. During this period, deponent, with the assistance of Dickerson and Dickerson, approached the Edison Electric Light Company to see if they would interest themselves in these Goebel inventions; the whole matter was gone over in the presence of Mr. Dickerson, Jr., and Major S. B. Eaton, of the Edison Company, and the conclusion was summed up by Mr. Dickerson, thus: "Even if Goebel did what he claims, it is nothing but an abandoned experiment;" deponent hoped that the Edison Company would be at least sufficiently impressed by Goebel's story of what he had done to get him out of the way; but they declined to negotiate, and the matter never went so far as to talk figures.

WILLIAM MCMAHON deposes that, in the early spring of 1881, he, with George Crosby and Edwin M. Fox, organized the American Electric Light Company; started a small shop in Centre street and tried unsuccessfully to make incandescent lamps. Crosby spoke several times of an old man named Goebel whom he thought would be useful in the business; went with Crosby and saw him in a watchmaker's shop in Grand street; found him entirely familiar with all the work, which had been done up to that time in electric lighting; he spoke highly of Edison and seemed to regard him as a great inventor; he spoke English well enough to be readily understood; he showed deponent an arc lamp with a glass cover over it about nine inches high; asked him if he had ever made an incandescent lamp and he said he had not; he said he thought he could make carbons for incandescent lamps; did not say that he ever had done so; saw a vacuum pump, which appeared to be a swinging pump attached to the wall; it was not like Edison's pump; don't remember that anything was said about the pump; saw no battery or incandescent lamps about the place. Deponent told Goebel that he could make him a very rich man, if he could show an incandescent lamp made prior to Edison's. Goebel replied "Well, we might make one that would look old, eh, George," which raised a general laugh; he afterwards asked deponent to give his own work, and this was done. Deponent heard last year, for the first time, that Goebel claimed to have done anything in incandescent lighting, when questioned on the subject in the interest of infringers of the Edison patent; told them emphatically that Goebel had never done anything in incandescent lighting; deponent then believed that Goebel was being used as a tool, knowing his pretensions to have invented the incandescent lamp were fraudulent. Goebel was never employed by the American Company to deponent's knowledge; Crosby may have employed him. In 1881 there was intense excitement about the electric light; everybody recognized that Edison had made the invention; if there had been any chance for an opposition company, unlimited capital could have been secured to develop it. There was every reason why it was then for the interest of Mr. Goebel and his son to disclose fully everything he might have done in the way of making incandescent lamps, if he had done anything. Deponent has recently been approached with a view to assuming that he remembered something tending to show that Goebel had made an incandescent lamp at an early date, but declined to do so, knowing that he had never done any such work. The first fiddle-bow lamp deponent ever saw was made in Boston, in 1882.

TIMOTHY G. MCMAHON says he accompanied Crosby and William McMahon on the visit to Goebel's shop in 1881; saw a glass water fountain in the front window; saw an arc lamp and a vacuum pump; saw some V-shaped carbons, supposed they had been brought by Crosby; Goebel made no claim to having made them; said he had never made an incandescent lamp, but had made an arc lamp, and that he would like to go into the incandescent lamp business; said he had never made any carbons; remember his saying he could make a lamp that would "look old." Deponent afterwards saw Goebel many times; he never claimed to have anticipated Edison's invention. About September, 1881, deponent, in company with a glass blower named Kuhn, spent an afternoon in Goebel's shop, and showed him how to exhaust and seal incandescent lamps, using bulbs and carbons taken from the shop of the American Company; this was the first time deponent ever saw an incandescent lamp in Goebel's place; Goebel never worked for the American Company to deponent's knowledge; his son was employed there for several months, but not to deponent's knowledge, on pumps or carbons. Crosby had known Goebel for many years. Deponent has made a sketch, representing the arc lamp, which Goebel showed him on his first visit to his place. The first fiddle-bow lamps were made in Boston and were then considered to be a way of evading Edison's claim for a horse-shoe carbon.

Otto A. Moses, mining engineer and chemist, entered the service of Mr. Edison in 1879; went to Paris in his behalf in 1882; was familiar with all his work; subsequently tried to construct an incandescent lamp, which would not infringe Mr. Edison's; heard of Goebel and called on him at his shop in Grand street in 1884: saw his glass blower's table and mercury pump; Goebel made some canes for deponent which deponent carbonized at his own laboratory. Goebel asserted confidentially to deponent that he (Goebel) was the inventor of the Edison lamp; that he had made them a great many years before; asked him to show some of his old lamps, but he had none to show; he never did show him any lamps, which he pretended had been made before the date referred to; conversed with him in German; he was extremely intelligent and keenly alive to the value of his services.

Ludwig K. Bohm is a consulting engineer and chemical expert; became an assistant of Mr. Edison in August, 1879; was superintendent of American Electric Light Company in 1881; while there invented the "stopper lamp" Knew George Crosby; he had worked in the carbonizing department at Edison's laboratory; deponent made Goebel's acquaintance at this time; went to his place; saw his mercury pump; he never once mentioned that he had made incandescent lamps earlier than Edison; accounts of Edison's work were published in the German newspapers and deponent thinks he must have been conversant with Edison's work and have recognized the great importance of an invention, which would have anticipated it. Deponent got the impression that Goebel was eager to obtain money, and that if he had had such an important invention he would certainly have presented it to the officers of the American Company. Deponent has read the affidavit of D. C. Voss; Voss was employed by deponent in the carbon department of the American Company; was very friendly with him; he never said anything about the lamps, which Goebel pretended to have made prior to Edison's invention; believes he would have done so if he had known of any such thing; deponent was a pupil of Dr. Geissler; he (Geissler) invented the mercurial pump in 1858; the vacuum tubes were invented about 1860; deponent knows of nothing on record showing that previous to this, electric currents could be introduced into glass vacuum tubes; believes that the state of the art was not sufficient to enable the production of such results as are claimed by Goebel to have been obtained in the early fifties. Had read Goebel's affidavit, describing how he exhausted his lamps; a vacuum produced in this way would not be sufficient to enable a filamentary carbon to last, because there is always air in the mercury, and air also clings to the glass walls, leaving sufficient in the lamp chamber to prevent the filamentary carbon from lasting. Mr. Goebel does not say that he boiled the mercury, which is necessary to get the air out of the mercury; the method of exhaustion described by Goebel is impracticable with filamentary carbon, because the carbons will be broken by the mercury; the "hair-pin" carbons in every instance, and a large proportion of the "meat-saw" carbons as well. Goebel's lamp shows very poor workmanship; No. 1, may never have burned or had a vacuum; No. 3, has concavities at the top where sealed off; these concavities are not proof that the vacuum in the lamp chamber was sufficiently high to make a filamentary carbon last. The exhibit lamp does not exhibit the partial decomposition upon the surface which they would be likely to, if allowed to lie for years exposed to atmospheric influences.

Albert Hetschel deposes that he is a glass blower and manufacturer of physical and chemical apparatus; was employed by the American Electric Light Company in the summer of 1881 to help Henry Goebel make incandescent lamps at his shop in Grand street; worked with him every day for four months, and became intimate with his family; he knew very little about lamp manufacturing; he tried to make filaments out of old paper; he had a crude vacuum pump; he made four little lamps from pieces of carbon, which he took from a Maxim lamp, mounted them in glass bulbs blown by deponent and hung them in his window; these were the only lamps he ever made while deponent was with him; was satisfied he did not have the capacity to make a lamp; he never said one word about having ever before done anything with incandescent lamps; never mentioned the subject in any way; was greatly surprised to learn from the newspapers last week that Goebel claimed to have invented the incandescent lamp before Edison. Goebel never said that he had ever made incandescent lamps before his employment by the American Company, nor did he claim any priority over Edison, although there was every opportunity and inducement for him to do so; deponent never heard until within the past week that Goebel claimed to have made incandescent lamps prior to Mr. Edison's invention.

A considerable number of witnesses make affidavit to having frequently been in Goebel's store in Monroe street or to having looked through his telescope on a wagon; none of them ever saw or heard of an electric lamp in connection therewith. Some remember lights on the wagon; there was nothing remarkable about them; think they were common oil lamps.

Major S. B. Eaton, in his affidavit, confirms the statements contained in the affidavit of W. C. Dreyer, but adds no matter of importance, except that in November, 1882, Henry Goebel, Jr., called and offered him, as representative of the Edison Company the inventions and good will of Goebel for $20,000; the company considered the matter and declined to purchase at any price.

John W. Howell, electrician of the Edison lamp works, deposed that lamps having leading-in wires of iron or copper will not hold a vacuum; does not believe that filamentary carbon lamps can be made in the manner described by Goebel in his affidavit; the concavities in No. 3 proved that it had a very low vacuum when it was sealed, and one entirely insufficient to preserve a filament at incandescence.

Franz Holzer, foreman of the glass department in the Edison lamp works at Harrison, N. J., confirms the statements of Mr. Howell.

Edward R. Knowles, deposes that he succeeded William Stanley, Jr., on June 5, 1882, as electrician of the American Electric Light Company; never saw Henry Goebel, but heard of him from employees of the shop. The story was circulated that he had made incandescent lamps prior to Mr. Edison; it made no particular impression on deponent's mind; one of the employees of the factory gave deponent a lamp which he said Goebel had made; it was given deponent as an old lamp. Deponent herewith produces what is left of it.

William Stanley, Jr., states that he is familiar with incandescent lamp manufacture; was connected with the American Electric Light Company, from the fall of 1880 to the summer of 1881; was superintendent and engineer; it was of great importance to the company to be able to make a lamp which would avoid the Edison patents; Henry Goebel was employed by the company; he made and mounted filaments and exhausted the lamps.

LETTERS TO THE EDITOR.

THE ST. LOUIS-CHICAGO ELECTRIC RAILWAY.

I recently saw the charge that the electrical press had not done its duty in warning the public against the Chicago and St. Louis Electric Railroad Company's project, characterizing it as a "wild-cat, through-by-lightning scheme" that was being worked on the unsophisticated public to obtain their cash for stock. The Engineer must then stand this charge, for I notice that it has taken no such radical stand.

Surely though, this cannot be the general opinion among the engineers. For who is to say, whether the scheme is practicable—someone who believes electricity will advance just so far and no farther in its application, or some *practical* engineer with broader ideas? I should like to hear the sentiments of some of this latter class upon this important enterprise.

J. Wilson Brown.

Brimfield, Mass., Jan. 19, 1893.

[Up to the present time The Electrical Engineer has not vouchsafed any opinion, one way or the other, as to the practicability of the St. Louis and Chicago electric railway scheme, projected by Dr. Wellington Adams. The reason for this will be clear when we point out that up to the present writing we have not been placed in possession of any of the working details of the methods to be adopted. It would, indeed, ill become anyone at this period to assert the impossibility of the successful accomplishment of an electric railway scheme, in the light of the experience of the last few years; but an undertaking such as that contemplated by Dr. Adams must for its success—and by success we mean financial as well as technical—depend upon many factors. Unfortunately we have still to see a thorough analysis of the scheme in all its bearings, upon which alone we would be prepared to base an opinion. The estimates of financial results of operation set forth in the advertisements of the company, strike us as very visionary, but whether their rosy nature is due to enthusiasm or to something worse, we cannot tell.—Eds. E. E.]

PAPERS TO BE READ AT THE N. E. L. A. CONVENTION IN ST. LOUIS.

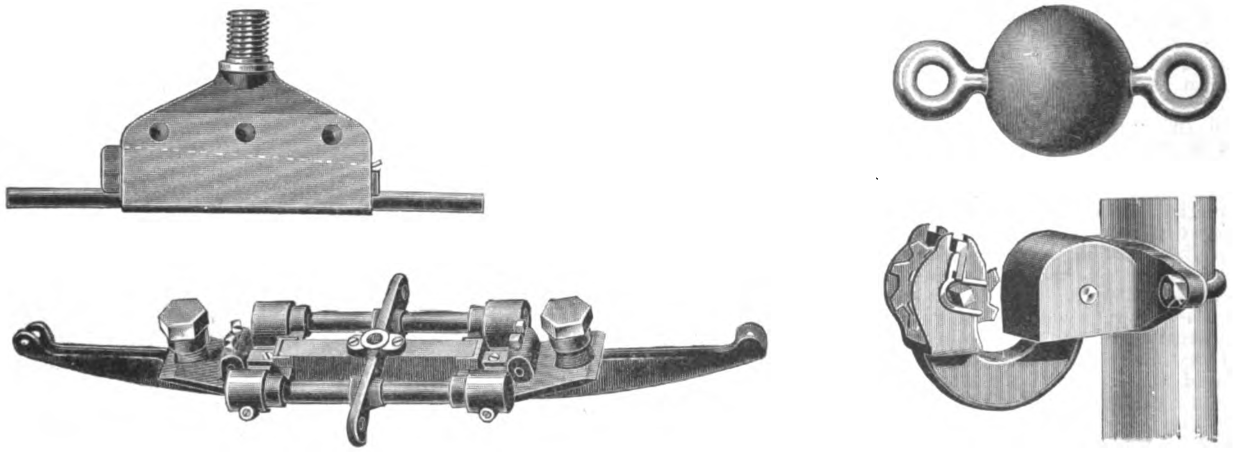
MR. GEORGE F. PORTER, secretary of the N. E. L. A. writes us, that in addition to the lecture by Mr. Tesla, in which he will give practical demonstrations of high frequency and high potential currents, the following papers will be read: "Some Experiences with the Alternating System," by Mr. Sterling; "Long Distance Transmission of Power," by Mr. C. S. Bradley; "Under What Conditions is the Use of Water-Power Economical?," by Mr. L. B. Stillwell; "Preservation of Poles and Cross Arms," by Mr. Myers; "The Incandescent Lamp," by Mr. Townley. Messrs. Stanley, Brophy, Bell, Armstrong, Browne and Adams have promised to read papers on subjects to be announced. Prof. Geo. Forbes, writes from London that in all probability he will attend the St. Louis Convention; and if possible prepare a paper.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

ELECTRIC RAILWAY APPLIANCES OF THE NEW YORK ELECTRICAL WORKS.

THE NEW YORK ELECTRICAL WORKS, of 161 Washington street, New York City, are introducing a number of interesting specialties in electric railway line material, some of which are shown in the accompanying illustrations. While the company realizes fully the fact that the best apparatus is none too good in this exacting class of work, they have endeavored to so simplify the construction as to produce articles that will be perfect, and, at the same time, not exorbitantly high in price.



FIGS.—1, 2, 3 AND 4.—ELECTRIC RAILWAY APPLIANCES OF THE NEW YORK ELECTRICAL WORKS.

Believing that the application of hot solder is detrimental to tempered copper wire they have made all their fittings with mechanical clamps so securely applied that the wire will give way outside the fitting before the clamp will yield.

Fig. 1 shows the mechanical trolley wire clip. As will be seen, a sheet of copper is bent around the wire and rivetted to the main body piece of the clip, a wedge being firmly driven in between the latter and the wire. This wedge has a slit at the small end which, by the blow of a cold chisel, is opened and the wedge securely locked. In the newer form of clip, hook shaped lugs are cast on the body piece, and the action of the wedge also holds the copper strap in place without the use of rivets.

Fig. 2 shows a strain insulator using the Medbery insulation. This material is manufactured by the Fiberite Company for the New York Electrical Works and is applied hydraulically under a pressure of 150 tons. In a recent tension test, one of the eye bolts was actually torn apart before the insulating material cracked appreciably. The Medbery compound is waterproof, and not brittle, and hence is especially adapted to line work where it is necessarily subjected to more or less rough usage. It is the invention of Mr. H. J. Medbery, of Mechanicsville, N. Y., who has long been interested in such work, and has made a number of highly ingenious improvements.

The circuit breaker, Fig. 3, is secured to the wire by rivetting together the ends lugs and forcing a clamping wedge into a groove, as in the other fittings made by this company. The construction is such that the entire destruction of the insulation will not affect the suspension of the trolley wire.

Fig. 4 shows a novel form of pole ratchet. An insulated sleeve and bushing separates the two parts and is kept well up inside of the hood. The ratchet device, as may be seen, is very simple and effective, and perfectly accessible to the lineman.

The New York Electrical Works are constantly experimenting with a view to improving their apparatus, and have produced some very creditable work.

THE "DIAMOND" TRANSFORMER WIRING RULE.

THE neat little catalogue just issued by Messrs. Taylor, Goodhue & Ames, of Chicago, on their "Diamond Transformers," besides giving an excellent description of the apparatus, contains in addition most useful information for station managers. Thus we may quote the following on the subject of "Wiring:"

Badly designed wiring from the transformer to the lamps often leads to variations of the candle power in the lamps that, almost without exception, is laid to poor regulation in the transformer. The voltage of the secondary circuits cannot increase to compensate for the loss in leads at heavy loads, and since the loss varies on any set of leads with the square of the load in amperes, it follows that the secondary wiring should be so designed that the loss will never exceed a very small predetermined amount.

When the transformers are placed so far from the lamps as to make the cost of leads excessive for the 50 volt distribution, the "3-point" type of transformer is almost a necessity. By simply making one connection, the voltage of secondary circuits is changed to 100 volts, reducing the size of wire in sectional area to supply a given number of lamps to one quarter of what would have been necessary on the 50 volt plan with a given per cent. of loss. In large buildings this is an extremely important item.

For the benefit of those desiring a simple formula for calculating leads for multiple distribution, we print the following:

$$\text{C. M.} = \frac{21.21 \times C \times D}{E}.$$

In this formula,

C. M. = Area of wire in circular mils.
21.21 = Constant for 2 mil feet of copper wire.
C = Current in amperes.
D = Distance in feet to lamps.
E = Volts loss in conductor.

THE COMMERCIAL ELECTRIC COMPANY.

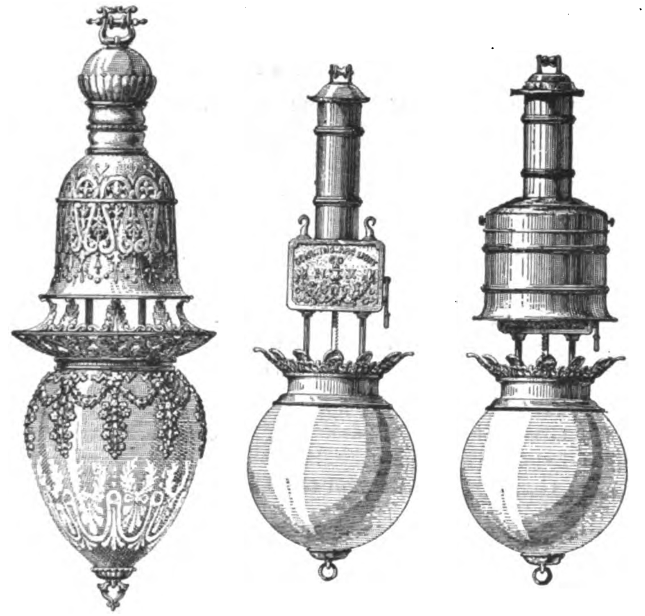
THE COMMERCIAL ELECTRIC COMPANY, of Indianapolis, has recently appointed the following agents: Chicago, Mr. Fred Wolfrum, 455 The "Rookery;" St. Louis, E. G. Bruckman, of the Electrical Engineering Company, Equitable Building; Louisville, Southern Engineering Company, 238 Fifth street; Cleveland, W. D. Graves, Electrical Manufacturing Company, 8 Case place; Toledo, Bissell & Dodge, 518 Summit street. The Commercial Company has in a short time built up what promises to be a very successful business for so young a concern. Mr. A. D. Adams, the manager and electrician of this company, has had a wide experience in this class of work and is the inventor of the apparatus the company is manufacturing.

Mr. Fred L. Wolfrum, the new Chicago agent, formerly represented the Detroit Motor Company, and later the Jenney Electric Motor Company, in Chicago. Mr. Wolfrum is a young man, but his very successful work in introducing the Jenney motor and the Detroit Motor Company's apparatus in Chicago has already placed him in the front rank.

THE GENERAL INCANDESCENT ARC LIGHT CO.'S NEW ARC LAMPS.

Considering the large increase in candle-power which can be attained for a certain expenditure of energy in the arc lamp as compared with incandescent lamp, it is strange that the arc lamp on incandescent circuits is not more in use to-day than we actually find it in practice. Nevertheless this method is steadily gaining ground and we are convinced that arc lamps on constant potential circuits will, in the near future, occupy a position quite as prominent as, if not more so, than the incandescent lamp itself. In order, however, that it may attain this desired preëminence the arc lamp must be of a character such that it will practically equal the incandescent lamp in steadiness of illumination, and on the other hand its range of illuminating power must be variable to suit the needs of each individual customer. To begin with the fiest consideration,—steadiness,—an arc lamp on a constant potential circuit must be able to take care of any variation in the voltage of the circuit from which it is operated, and to which these circuits are necessarily subject from time to time. Again, the consumer must be able to vary the candle-power of his lamp without causing the substitution of a new lamp, or the introduction of any auxiliary apparatus.

With these general objects in view The General Incandescent Arc Light Co. of this city, have just brought out a series of new lamps which possess a number of most interesting features that were well illustrated in a recent test which we had the pleasure of witnessing. The lamp itself has a most simple mechanism embodying but one magnet and three wheels with a single spring, and without a dash-pot. The upper carbon holder has a very simple universal joint which permits the carbon to be lined up perfectly true, independent of any curvature in the carbon itself.



General Incandescent Arc Light Co.'s New Arc Lamps.

One of the most serious expenses in the operation of arc lamps is the globe breakage, which is due almost entirely to the necessity of removing the globe when trimming the lamp. The present lamp is so designed that the globe is not disturbed during trimming. This is accomplished by making the lower carbon holder removable from the bottom of the lamp; the holder consists of a slotted screw which automatically grips the carbon when the holder is screwed home in the bottom of the lamp. Both the upper and lower carbon holders are arranged to take any sized carbon.

The standard lamps are run 2 in series, but one of the most marked characteristics of the new lamp, and one which will be at once appreciated by central station managers as well as by the owners of isolated plants, consists in the fact that these lamps can be run up to 6 amperes at present, three in series, on a 110 volt circuit, or six in series on a 220 volt circuit. The enormous gain effected by this method of operation will be readily apparent when we consider that in the ordinary method of running arc lamps on constant potential circuits a very large proportion of the energy is consumed in the resistance which it is necessary to include in series with them. Thus, taking the ordinary 110-volt circuit with two arc lamps in series, each operating at 42-volts, there would be 84-volts consumed in the lamps proper while no less than 26-volts would be consumed in overcoming the resistance, thus involving a loss of nearly 25 per cent. in current energy. With the lamps we are describing, and which are operated three in series, each lamp takes 35-volts, making a total of 105-volts consumed in the lamps and only 5-volts consumed in overcoming the resistances in series, and hence involving a loss of only five per cent., that is to say one-fifth the amount lost in the previous case.

While the aggregate illuminating candle power of each series is not only considerably greater than that of the two lamps in series, it is obvious that the three lamps permit of a much better distribution of the light than could possibly be obtained with two, so that in this respect also the gain in illumination is considerable.

We have already referred to the necessity of arc lamps on incandescent circuits being able to operate at varying voltages without adjustment. Some experiments we have witnessed on this point give remarkable proof of the excellent design of the General Incendescent Arc Light Company's new lamps. Thus three lamps in series operating at a normal potential of 110 volts had their potential increased until it reached 120 volts. Not the slightest flicker or tremor in the arc could be noticed, the only effect being the increase of the illuminating power of the lamp. Starting at 120 the potential was then decreased to 100 volts, that is, 10 volts below normal, and still without any effect on the lamps except a natural decrease in candle power. When we consider the frequency with which the voltage on constant potential circuits is apt to vary, this quality of the lamp will be throughly appreciated by both central station managers and owners of isolated plants.

But in addition to this excellent quality of the lamp it frequently happens that the customer desires to increase the candle power of his lamp, or to decrease it, which may be readily accomplished by increasing the current in the lamp. To attain this end each lamp is provided with a resistance which is placed on the top of the lamp and surrounding the upper carbon tube. We witnessed an experiment demonstrating the fact that the lamp can run with a current of from 8 to 20 amperes without a single re-adjustment of the lamp mechanism proper, all that was necessary being the shifting of the contact on an external resistance connected in series with the lamp. On the rack-rod lamp the resistance is attached to the lamp itself and, we may add, is insulated from the body of the lamp by porcelain insulators, thus avoiding the leakage which occurs when asbestos is employed and which is apt to absorb moisture. An external resistance has also been designed which may be placed at any convenient point in the circuit, and which can be readily gotten at without touching the lamp. For this purpose a frame has been designed upon which the German silver wire is wound on porcelain saddles, thus making a perfectly fire and moisture proof construction.

Various styles of these lamps from the ordinary plain type to the most ornate, have been designed by the company, a few of which are illustrated in the accompanying engravings. The lamp designed to burn twelve hours is 42 inches in length and weighs only 18 pounds, operating three in series at six amperes and giving between 700 and 800 c. p. each. The 8 and 10 ampere lamps operating 2 series give respectively about 1000 and 1300 c. p.

For low ceilings and with a view to supplying a demand which is bound to occur at no distant day the company has designed, and will shortly introduce, a small ribbon lamp, which is called the Bijou lamp and which is admirably adapted for interior illumination for the smallest apartments, and the illumination of which can be varied from 150 c. p. up, like that of the larger lamps. The steadiness of this smaller lamp, which we have seen in operation is equal to that of the incandescent lamp, so that the old objection as to the unsteadiness of the arc light and hence its unfitness of the illumination of living rooms is now a thing of the past; and we believe the day is not far distant when the small arc lamp will be seen in the salon as well as in the public hall.

The General Incandescent Arc Light Company, of which Mr. S. Bergmann is president, has its general office at the corner of Duane and Elm streets, New York City, with show-rooms at No. 275 Fifth avenue. The works of the Company occupy a large building which it owns on the corner of Thirty-third street and First avenue, where the smallest details of the lamp are manufactured on the spot, the equipment of the factory being admirable in every respect.

NEW SUBWAYS FOR ELECTRIC WIRES IN NEW YORK.

The Board of Electrical Control has adopted a resolution directing the engineer to report a district below Fifty-ninth street, east or west, in which the poles can be taken down and subways built. The Board granted permits to the Metropolitan Telephone Company, Mt. Morris, Edison, Manhattan, and Harlem Electric Lighting Companies, and the Empire Subway Company to build subways in about one hundred and fifty streets below Eightieth street.

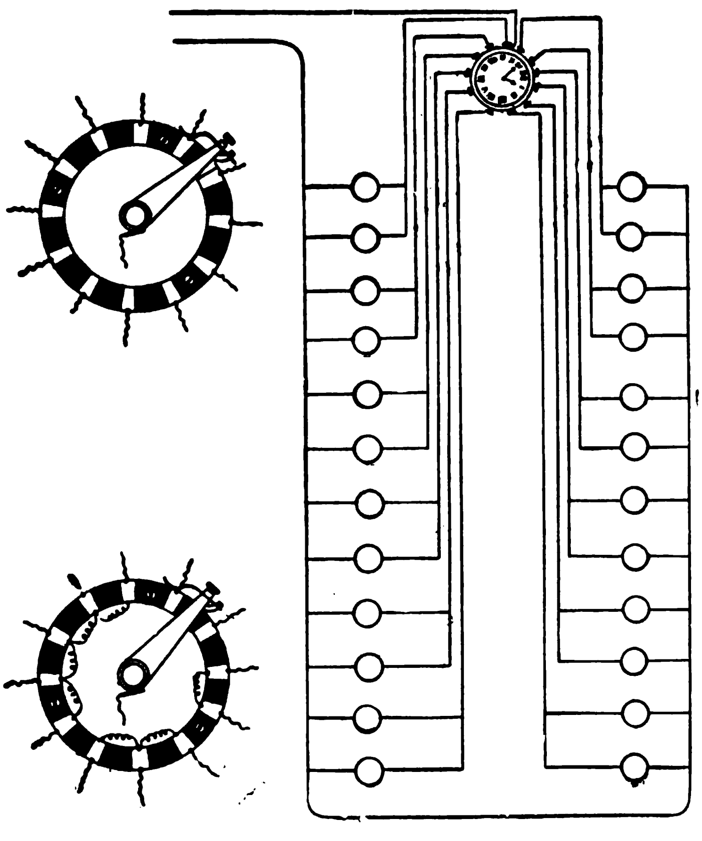
It was decided to permit no subways to be built in newly paved streets, and the companies were informed that if they desired subways in the streets which have been designated to be repaved they must be active.

ELECTRICAL DISPLAY ADVERTISING.

A UNIQUE invention in connecton with display electrical advertising in street cars operated by electricity has been made by Mr. H. T. Richards, advertising manager of the *Electrical Review*, New York. Mounted along the ordinary advertising space, on both sides of the car, is placed in neat frames, glass of any shade ground on one side, cut in the usual size of the street car advertising panel, and concealed behind this glass are placed incandescent lamps and reflectors.

The advertising copy used with this invention is of sheet-iron, tin, cardboard or any opaque substance, that which corresponds to type, trade-marks or designs being cut out to allow the light to shine through.

The strongest feature of this invention, from the advertiser's standpoint, is the fact that only one advertisement is illuminated at a time. The light behind the one illuminated is allowed to burn steadily for from half a minute to a minute, when it dissappears without noise or warning as suddenly as it came. After a slight interval another panel comes into life and light with the same length of display; and so by the same process all the panels or advertisements are illuminated one at a time. When an advertiser requires two or more panels for his advertisement, they can of course be operated simultaneously.



RICHARDS' ELECTRICAL DISPLAY ADVERTISING DEVICE.

The electrical device which operates these advertisements is shown in the accompanying illustration.

The current used in driving the car lights the lamps, and a clock placed in the car serves the double function of telling the time and furnishing the means of periodically illuminating the panels. The circuit connections are so arranged that an automatic circuit closer, controlled by the clock, will cut into and out of action, successively, the lamps behind the several panels.

This mode of advertising is as practicable during the day as in the evening, as the advertising space is immediately surrounded by the solid walls of the car, and, the lamps being placed against the dark background, there will be no difficulty in seeing the light.

AN IMPORTANT ELECTRICAL INDUSTRY FOR DULUTH.

A POWERFUL combination of electrical companies has been organized into a new corporation which will make Duluth its headquarters for the manufacture and sale of every class of apparatus for light, power, traction, etc.

The organization of the Great Western Manufacturing Company has just been completed. Its articles of incorporation have been filed and its officers elected. The company is a consolidation of five concerns each of which was a large institution. In the consolidation are included the Great Western Electrical Supply Company of Chicago, the Chicago Insulated Wire Company of Sycamore, Ill., the Phœnix Manufacturing Company of Duluth, the Bain Electrical Manufacturing Company of Chicago. The capital stock of the consolidated companies is $1,500,000, of which sum $1,300,000 has been paid over in stock for the various plants absorbed. There has been issued also $200,000 of preferred stock for a working capital. Of this last sum $100,000 has been taken up in the East. Duluth has taken the other $100,000.

The men behind the new company are in themselves all the guarantee needed to assure its stability and good management. The officers chosen are: President, T. P. Casey, formerly vice-president and now director of the Northwestern National Bank of Minneapolis; first vice-president and managing director, R. S. Munger; second vice-president, Hon. Stephen J. Young, president of the Union National Bank, Brunswick, Me.; third vice-president and assistant treasurer, O. H. Simonds, general manager of the West Duluth Land Company; secretary and treasurer, H. A. Odell, of Chicago; general manager, E. R. Gilman, formerly president of the Northwestern Thomson-Houston Company, of St. Paul; assistant general manager, T. C. Rafferty.

Among the stockholders are such men as ex-Gov. Merriam, whose personal representative in the management is Mr. Odell, Col. C. H. Graves, Clinton Markell, Joseph Selwood, Clague & Prindle, Pantou & Watson, R. M. Newport, St. Paul, A. Harrington and many others, among them men of national reputation in the world of industry and finance.

As would be expected from such a company the plan of operation is very wide in its scope. When the business is in full operation anything can be furnished from a push-button to a fully equipped electrical street car line.

PHILADELPHIA NOTES.

MESSRS. QUEEN & CO., INCORPORATED, Philadelphia, report a steady demand for their portable photometer, which accurately measures the candle power of incandescent lamps, and can be used wherever desired. It is very important from an economical standpoint, for a central station manager to use lamps that give the greatest illumination for energy consumed and this convenient apparatus enables comparisons of different types to be quickly made. When a customer complains of poor light an impartial test will settle the dispute much more quickly than words, and there is no appeal. The makers issue descriptive circular No. 295, which gives full particulars of the device.

HARRY S. SMITH & CO. LIMITED, have been appointed agents for Philadelphia and vicinity for the Dewey Electric Heating Company's apparatus. The company are placing a 60 light plant at Cramp's Gun Factory, a 200 light plant for W. W. Bache & Company, wiring Haddon Hall and the New Casino at Atlantic City, and report a thriving business generally.

MR. G. A. WILBUR, agent for the Fort Wayne Electric Company, has contracted to place two 60 and one 80 Wood arc light machine with 200 arc lamps in the station of the Powelton Electric Company of West Philadelphia. They have also received their fourth order for a 1,000 light Slattery alternator from the same company.

MR. C. S. CLUNN, mechanical and electrical engineer, of 1,217 Filbert street, has closed a contract for an incandescent plant of 500 lights to be fed by a C. and P. Dynamo at Moore's Windsor Hotel. A 50 H. P. Valley automatic engine, boilers, feed pump, etc., are included in the plant.

WESTERN NOTES.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., will build the new machine shop for S. F. Hodge & Co., Detroit, Mich. The building will be 150 feet long and of the modern type, the central portion being 40 feet in width controlled by a traveling crane of 20 tons capacity, with a wing on each side 22 feet in width, the wings being two stories high. When completed it will be one of the best machine shops in the North-West.

WM. H. MCKINLOCK, president of the Central Electric Company, has just returned from a short trip in the east, where he has perfected arrangements for the introduction and sale of several new specialties, which, when put on the market, are expected to create considerable attention and interest in the electrical trade.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XV. FEBRUARY 15, 1893. No. 250.

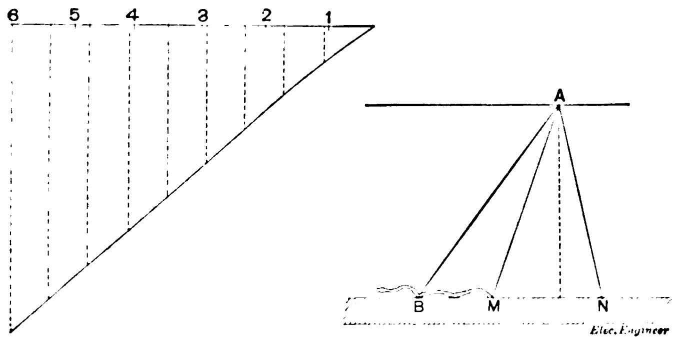
THE THEORY OF SUBMARINE CABLE LAYING.—I.

BY

Geo L Littlehales.

THE form of the curve assumed by a submarine cable during the process of laying and the different tensions to which it is subjected under the various conditions which arise were first investigated by Sir William Thomson who published his results in October, 1857. In the following February, Messrs. Longridge and Brooks laid before the Institute of Civil Engineers, at London, a complete mathematical analysis of the conditions which obtain in cable laying, basing their reasoning upon the proposition that the resistance experienced by a cylinder in moving through water in the direction of its axis varies as the square of the velocity. The dictates of this theory were followed in the practical laying of cables up to 1874, when Dr. Werner Siemens presented to the Berlin Academy of Sciences a new theory based upon the law of simple proportionality between the resistance and the velocity in the case of a cylinder of small diameter relative to its length moving in the direction of its axis through water, to which he had been led by his own experiments and by the experiments of Poiseuille concerning the motion of liquids in capillary tubes, and also by the statements of Newton and Coulomb.

Other experiments made in 1856 with the tubes of the pneumatic service in Berlin, had proved to Dr. Siemens that with tubes of large section and with considerable velocities, the law is more complex and may be represented by an expression of the form $av + bv^2$, in which v is the velocity of the cylinder and a and b are constants of which the second is small and can be neglected for values of v which do not surpass a certain limit.



FIGS. 1 AND 2.

The theory which is here given is that which has governed practical cable laying for the last seventeen years. In it the law of simple proportionality between the resistance opposed to the motion of a cylinder in the direction of its axis and its velocity is admitted, and the views of Dr. Siemens are, in the main, presented. All authors agree that when a cable is moved through water in a direction perpendicular to its length the resistance varies as the square of the velocity with which the cable is moved.

When a cable is paid out without tension from a ship moving with a uniform velocity, it will pass in nearly a straight line from the surface to the bottom of the ocean. This will appear by supposing that a ship, moving at a uniform speed, lets drop at equal intervals, balls of the same density and diameter as the cable, Fig. 1.

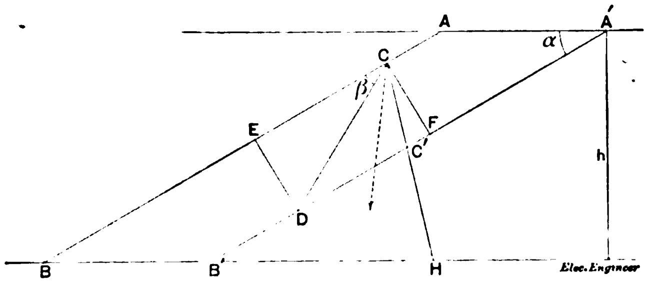


FIG. 3.

On account of the resistance which the water opposes to the descent of these balls, their motion, in a vertical direction, will soon become uniform, for it has been shown that a ball of the same density and diameter as the first Atlantic cable would acquire, in $\frac{6}{10}$ of a second, a velocity of 39.32 inches per second which differs from its final velocity by only $\frac{1}{3000}$. Therefore, the vertical space passed over by any ball up to a given instant is nearly proportional to the time elapsed since the ball was dropped and consequently to the distance passed over by the ship since the ball was dropped, and the centers of all the balls will be found at any moment to lie on a nearly straight line drawn obliquely between the surface and the bottom, whose inclination depends solely on the velocity of the ship.

If the centres of these balls be supposed to be joined by an infinitely thin thread to which the water can oppose no resistance, a sort of cable will be formed which can be paid out without tension and whose slack will depend only on its inclination and consequently on the velocity of the ship.

The part of a submarine cable suspended in the water during the laying, being very flexible on account of its great length, can be considered as being made up of independent elements. But each of these elements rests upon a kind of inclined plane formed by the layer of water in contact with it and is forced in a direction opposite to the course of the ship instead of falling vertically like the balls referred to. Thus the element A, Fig. 2, instead of coming to a point N, such that $BN = BA$, will arrive at an intermediate point M, and the whole length of the cable paid out will occupy a sinuous curve between the points B and M. Therefore the expression $\frac{AB - BM}{BM}$ will represent the percentage of loss or the slack of the cable.

In Fig. 3, let A B represent the initial position of the cable; A A′, the space passed over by the ship in a unit of time; and A′ B′, the new position of the cable at the end of a unit of time. Any point C of A B, instead of coming to the point C′ determined by the intersection of A′ B′ with a line CH, such that BH = BC, will follow the line CD and come to D. If the displacement CD be decomposed into two parts, CE and CF, lying respectively parallel and perpendicular to the direction of the cable, C′D will represent the excess of cable paid out in a unit of time and consequently $\frac{C'D}{A'A}$, the slack.

Let α represent the angle formed by the direction of the part of the cable undergoing submergence with the horizon ;
β, the angle formed by this direction with the direction followed by each element of cable during its descent into the water ;
f, the force with which the brake retains the cable on board the ship ;
h, the depth of the ocean at the point where the cable touches bottom ;
l, the length of the cable suspended in a straight line in the water ;
m, the slack ;
p, the weight in water of a unit of length of the cable ;
q, the cöefficient of longitudinal friction of the water on the cable, or the resistance which the water opposes to the motion, in the direction of its axis, of a cylinder or cable of unit length moving with a unit of velocity ;
r, the coefficient of transverse friction including the resistance which is overcome in displacing the water when the motion takes place in a direction perpendicular to the axis of the cable, or the resistance which the water opposes to the motion, in a direction perpendicular to its axis, of a cylinder or cable of unit length moving with a unit velocity ;
t, the constant velocity with which the cable falls in the water with its axis vertical ;
u, the velocity of its fall with its axis horizontal ; and
v, the constant velocity of the ship.

The quantities t, u, and p have special values for each cable, which are determined by experiment before laying.

They are connected with the coefficients q and r by the following relations :

$$p = q\,t \qquad (1)$$

$$p = r\,u^2 \qquad (2).$$

The weight $p\,l$ of the cable may be decomposed into two forces, one $p\,l \sin\alpha$ directed along its axis in the opposite direction to that in which the force of longitudinal friction and the holding of the brake is exerted, and the other $p\,l \cos\alpha$ perpendicular to the direction of the cable and opposed to the force of transverse friction and the displacement of the water. As the motion of the cable is uniform, all the forces acting upon it must be in equilibrium. Therefore

$$p\,l \sin\alpha - q \times \text{CE} \times l - f = 0 \qquad (3)$$

$$p\,l \cos\alpha - r \times \text{CF}^2 \times l = 0 \qquad (4).$$

In the second of these equations, replacing CF by its value $v \sin\alpha$ and p by its equivalent $r\,u^2$ as derived from equation (2), we have

$$\cos^2\alpha + \frac{u^2}{v^2}\cos\alpha - 1 = 0 \qquad (5),$$

$$\text{from which } \cos\alpha = -\frac{u^2}{2\,v^2} + \sqrt{1 + \frac{u^4}{4\,v^4}} \qquad (6).$$

The minus sign is neglected before the radical because the angle α is always smaller than 90° and consequently its cosine is always positive.

Solving equation (5) for $\frac{u}{v}$, we have

$$\frac{u}{v} = \frac{\sin\alpha}{\sqrt{\cos\alpha}} = \tan\alpha\,\sqrt{\cos\alpha} \qquad (7).$$

Since the triangle BCH is isosceles, BCH $= 90° - \frac{\alpha}{2}$; and since BCF $= 90°$, C′CF $= \frac{\alpha}{2}$. Substituting in (3) the value CE = FC′ + C′D $= v \sin\alpha \tan\frac{\alpha}{2} + m\,v$ and the value $l = \frac{h}{\sin\alpha}$, we have

$$f = p\,h - \frac{v}{t}\,p\,h\left(\tan\frac{\alpha}{2} + \frac{m}{\sin\alpha}\right) \qquad (8).$$

In the above equation when $v = 0$, which is the case which arises when the ship is for any reason stopped during the immersion of the cable, f, or the force with which the brake must restrain the cable to prevent its paying out, has its maximum value, ph, which is the weight in sea water of a length of the cable sufficient to hang vertically from the surface to the bottom of the ocean.

This value ph is also a measure of the restraining force which the brake must exert when the ship moves with sufficient velocity to lay the cable without slack.

$$\text{Putting } Q = \frac{v}{t}\,ph \tan\frac{\alpha}{2} \qquad (9)$$

$$\text{and} \quad R = \frac{v}{t}\,ph\,\frac{m}{\sin\alpha} \qquad (10),$$

equation (8) may be written in the following form :

$$f = ph - Q - R;$$

and, by examining the derivation of equation (8), it will appear that

$$Q = ql \times FC', \text{ and } R = ql \times C'D.$$

Consequently Q represents the amount of the longitudinal friction of the water on the cable when it is laid without slack ; and R, the longitudinal friction on the slack alone.

Calling P the force which retains the cable on board when it is paid out so as to be laid without slack, we have :

$$P = ph - \frac{v}{t}\,ph \tan\frac{\alpha}{2} = ph - Q \qquad (11).$$

To obtain a fuller account of the influence of v, the speed of the ship, upon the values Q and R, an examination of the values of P, Q, R, f, and α in the case of an Atlantic cable are here given. According to Longridge and Brooks the constants of this cable are :

p = 0.336 pounds to the foot,
t = 22.96 feet per second,
u = 3.28 feet per second.

If we suppose the cable to be laid in a depth of 1330 fathoms with a slack of 10 per cent., P, Q, R, f, and α will have the following values for velocities of the ship ranging from two to ten knots per hour :

v	2 Knots.	4 Knots.	6 Knots.	8 Knots.	10 Knots.
	lbs.	lbs.	lbs.	lbs.	lbs.
P	2872.2	2866.1	2865.9	2865.7	2866.4
Q	214.3	220.4	220.6	220.7	220.1
R	56.1	187.3	408.0	716.5	1114.1
f	2816.1	2678.7	2457.9	2149.2	2149.2
α	54°-50′	28°-05′	18°-55′	14°-15′	11°-25′

ph = 3086 lbs.

From the above table it will appear that the restraining force of the brake and the longitudinal friction of the water are, when the cable is laid without slack, almost independent of the speed of the ship, but remain proportional to the depth, h ; that the longitudinal friction on the slack of the cable is proportional to the square of the speed of the ship; and that the effective hold to be exercised by the brake diminishes at the same time that the friction increases in such a manner that the sum of these two forces remains about constant for variable values of v. It also appears that the angle of immersion of the cable diminishes rapidly as the speed of the ship increases.

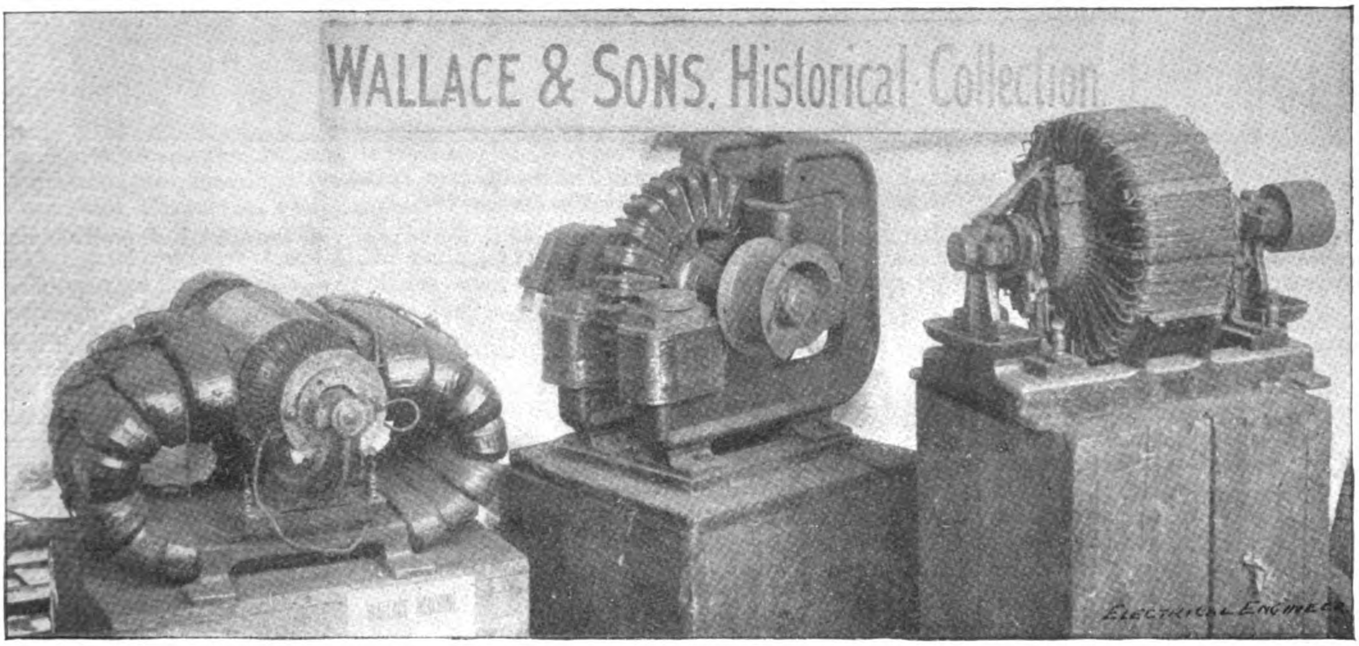
WILLIAM WALLACE, AND HIS CONTRIBUTIONS TO THE ELECTRICAL INDUSTRIES.[1]—III.

BY

Wm. J. Hammer

VII.

Another type of low tension dynamo was constructed by Mr. Wallace in 1876 for the Western Union Telegraph Company to take the place of batteries. The armature consists of a series of coils mounted side by side on the shaft in a manner identical with the Crompton-Burgin armature of England to which it bears a striking resemblance and which it antedates.



WALLACE'S DYNAMOS OF 1878 AND 1879.

The cut here represents three of many types of experimental dynamos built by Mr. Wallace. The one to the right of the illustration was constructed in 1879 in conjunction with Mr. Henry Edmunds, now of London, but at that time in Mr. Wallace's employ. It has a double-wound Gramme ring with two commutators and a circular field enclosing the armature. The machine in the centre was also built in 1879, and shows a peculiar form of field and an armature of the Pacinotti type. To the left is shown a dynamo not unlike in general construction an inverted Mather machine, as made to-day. The field magnet consists of a huge horseshoe magnet wound in sections and an armature of the Siemens type. The old machine of Prof. Jurgensen, of Copenhagen, is even more like it in appearance. It was built subsequently to Wallace's and is mainly interesting because it employed internal magnets to act on the inner windings of the Gramme ring armature. This was constructed on Feb. 2, 1878. It is interesting in examining the early machines made by Mr. Wallace to note the steps taken to increase the efficiency of the machine, which more extended knowledge of both theory and practice to-day enable us to endorse most highly. As examples of this, note that the armature of the Telemachon dynamo, had its core made of laminated plates, which is claimed to be the first ever made thus, and in the centre dynamo on this page note the form of the field and the method of winding the coils so as to bunch the greatest number of turns as near the end of the pole-piece as possible. Note also the application of the rocker arm to the 1874 dynamo, and other features which will suggest themselves upon an examination of the cuts shown.

VIII.

One of the most important projects carried out by Mr. William Wallace, in conjunction with his brother Thomas, was the construction of the enormous electro-deposition plant adjoining their works in Ansonia, for the purpose of plating with copper the steel wire used by the Postal Telegraph Company in conjunction with Prof. Elisha Gray's Harmonic Telegraph between New York and other large cities, notably Washington, Chicago and St. Louis. The circuit to St. Louis, via Chicago, was 1,300 miles in length, and consisted of two wires each, with 200 pounds of steel core and 500 pounds of copper plating per mile. The actual length of line from New York to Chicago was 1,027 miles, and in view of the widespread interest manifested in the recent opening to the public of the line of the Long Distance Telephone Company between New York and Chicago, 960 miles in length, it is interesting, historically, to note that the steel cored copper wire of the Postal Telegraph Company was telephoned over from this city to Chicago almost ten years ago, as is shown by the appended extract from the diary of Mr. H. Cummins, at that time vice-president and general manager of the Postal Telegraph Company, under whose entire charge and supervision the lines of the company were:

> "Sunday, March 25, 1883. To-day we got our wire connected to Chicago on the Postal Telegraph line. It tested 1,522 ohms resistance, much better than we expected. Prof. Gray and I talked

---

[1] Copyright, 1898, by W. J. Hammer.

with Theo. F. Taylor in Chicago by telephone over the wire, the greatest feat ever accomplished. I received the first message over the line. This is a great day for me, two years' hard labor now crowned with great success, even beyond my sanguine expectations. Whipple and Pogue were also present and much enthused. I breakfasted with Whipple at Taylor's Hotel, Jersey City. Roberts called on me in the evening at my house and we discussed my program with the Bell Telephone Company people."

Subsequently many prominent people telephoned over this line and at different periods since telephone experiments have been conducted, notably at the time of Van Ryssellberghe's visit to this country about seven years ago.

It is also interesting to note that not only did Mr. Wallace manufacture this wire, but the greater portion of the hard-drawn copper wire used in the circuit now established for the Long Distance Telephone. Thanks to various parties, and especially Prof. L. H. Laudy, of Columbia College, a warm friend of Mr. Wallace, I have secured some interesting data relative to the capacity of the electric deposition plant referred to above.

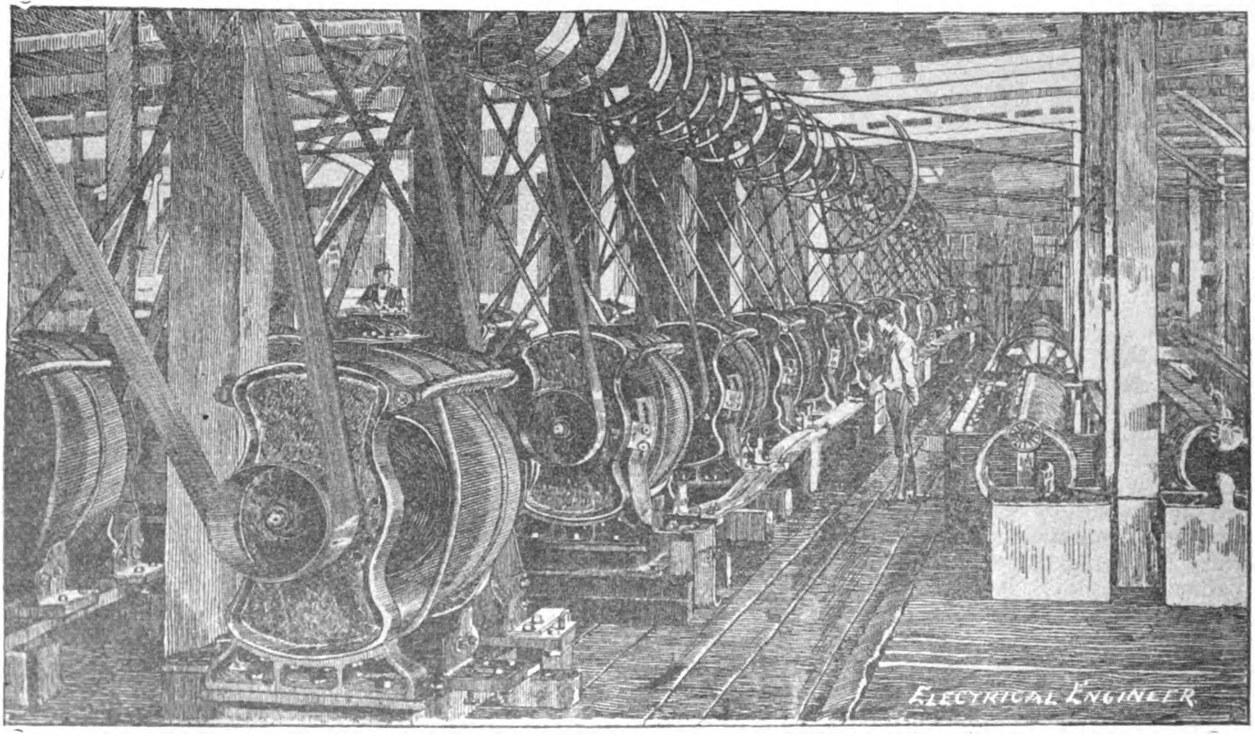
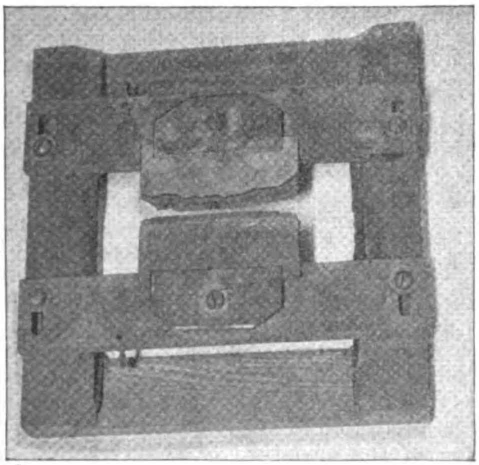
WALLACE & SONS' ELECTRO-DEPOSITION PLANT—PLATING TROUGHS.
(Fac-Simile Reproduction From New York Daily Graphic.)



WALLACE & SONS' ELECTRO-DEPOSITION DYNAMO PLANT—DYNAMO DEPARTMENT.
(Fac-Simile Reproduction From New York Daily Graphic.)

IX.

The accompanying illustrations on this page, which appeared originally in the *New York Graphic*, and are, I believe, the only illustrations ever made of this marvelous installation, give a slight idea of the dynamo plant and the arrangement of the plating baths. The former consisted of not less than 31 huge Wallace dynamos, each capable of raising to a white heat 18 feet of No. 4 copper wire, and Prof. Barker and others inform me that so powerful was the current produced by one of these enormous machines that an eight inch iron bolt held in the hand under the copper rods leading from the dynamo was drawn to it and remained attached thereto. There were in all 180 troughs, each holding 180 gallons of $CuSO_4$ solution, in all 32,400 gallons. Suspended in each trough were 1,700 pounds of copper anodes, making a total of 300,000 pounds in the 180 troughs. The anodes were suspended at the sides of the tank from a heavy copper bar, 3 inches by ¾ of an inch, which ran from end to end of the tank. The cathode was represented by the steel wire which was fed spirally in at one end of the tank over a revolving copper cylinder or tube suspended above and not in contact with the sulphate of copper. As the tube was connected with one terminal of the plating machines the wire which was itself submerged in the solution received during its passage its heavy coating of copper. Over 100 miles of steel wire at a time were thus treated. An arrangement similar to a huge glass comb was placed on each side of the tank and kept the spirals an equal distance apart. This plant, doubtless the largest of its kind ever constructed, is to-day but a reminiscence. It was purchased from Messrs. Wallace & Sons by Mr. John W. Mackay, representing the Postal Telegraph Company. Shortly after its introduction by Wallace & Sons, hard-drawn copper wire, possessing not only the necessary tensile strength, but high conductivity as well, (notwithstanding the prevailing impression at that time that hard-drawn copper must of necessity be of far lower conductivity than soft copper) was found to obviate the use of steel-cored copper wire, which was necessarily much more expensive; and soon thereafter the plant was re-sold and consigned to the scrap heap.



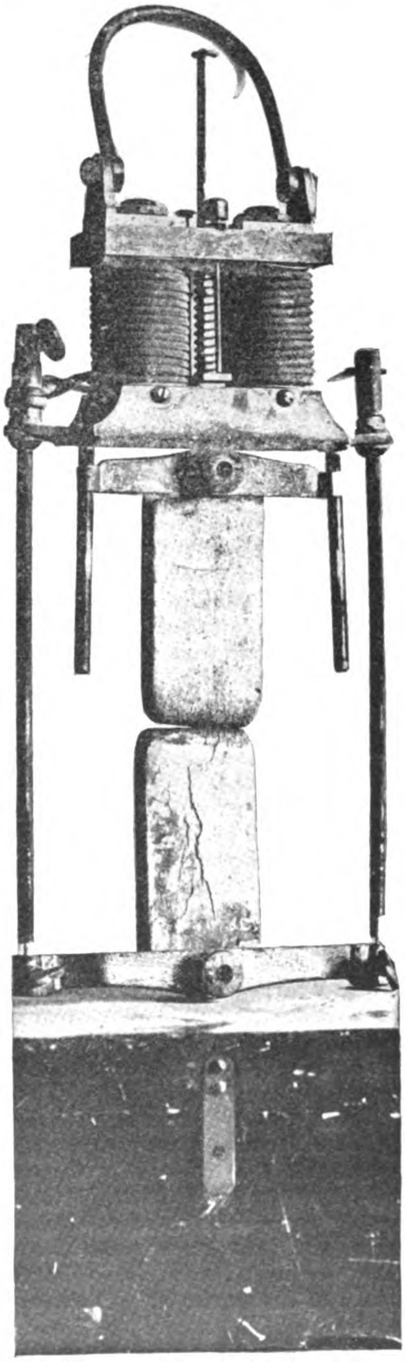
The First Arc Lamp Made in America.

In this connection it is interesting to show a comparison between the resistances of hard and soft-drawn copper wire. A piece one metre in length and one millimetre in diameter of chemically pure copper at 0° centigrade will measure when annealed 0.02034 Legal or Paris Ohm, and the same hard-drawn will measure 0.02081 Legal Ohm.

X.

Mr. Wallace invented and constructed the first arc lamp made in this country, an illustration of which is shown on this page. It consists of two plates of battery carbon fastened in a wooden frame, the carbons being fastened to cross-pieces near the top and bottom of the frame by broad brass clamps and screws. The carbons could be adjusted by hand as indicated by the slot and supporting screws observable in the ends of each cross-bar; although Mr. Wallace informs me they usually kept a small boy with a hammer busy going from lamp to lamp and driving the plates together. This form of regulator for an arc lamp it suffices to say was not patented. The arc was established by means of a piece of wire or carbon drawn across the edges of the two plates, after which it would continue to burn for a long time, the arc moving lengthwise across the plate, constantly seeking the path of least resistance.

This lamp was constructed early in 1875 and shortly thereafter Mr. Wallace replaced the wooden frame by a metallic one. The two slides in the frame each held a carbon plate 12 inches long by 2½ wide and half an inch thick. These slides and carbon holders were insulated from one another, the upper one being connected with an electromagnet in series with the carbons which by its action on an armature and clutch separated the carbons and established the arc as soon as the circuit was closed by gravitation. This lamp was a remarkable improvement in simplicity and economy as compared with the intricate and



One of the First Four Arc Lamps Ever Run in Series.

expensive lamps constructed abroad by Serrin and others; the Wallace lamp would burn for 10 nights of 10 hours each. Mr. Wallace has the distinguished honor of being the first person to run arc lamps in series, and on page 159 is shown one of the first four lamps ever burned in this manner. They were used for several months in the works of Wallace & Sons, and this particular lamp is now in the possession of Columbia College and exhibited among its most valued scientific treasures. I am indebted to Prof. L. H. Laudy for the photo shown, which he kindly took for me. In this connection, I may add that one of Mr. Wallace's first dynamos was sent to Columbia College for the School of Mines, and was used there for electrical projection for spectrum analysis with the arc. Prior to that, the School had used primary batteries. The dynamo is to-day one of the prized possessions of the School of Mines.

LAMINATED OR DIVIDED IRON AND OTHER METALLIC MASSES IN ELECTROMAGNETIC APPARATUS.—VII.

BY

Thos D Lockwood

Edward Weston.

RETURNING to English patents we have to mention four issued in 1877. These are: No. 4432, Nov. 24, J. Rapieff; No. 4435, Nov. 24, S. A. Varley; No. 4464, Nov. 27, L. Simon; No. 4903, Dec. 27, W. R. Lake. The last two patentees, are simply attorneys; Simon representing S. Shückert, and Lake representing Weston.

The Rapieff patent is an enormous affair of 42 pages, but as respects the generator which it describes, it points out that: "To obviate the inconvenience of retarded magnetization due to mutual induction in systems of bobbins, the cores of such bobbins are made up of a series of thin electromagnets with their like poles similarly placed." In Varley's patent, the revolving bobbins have each a wooden core surrounded with a number of iron wires arranged parallel to the axis of the core. The Shückert machine, being a modified Gramme—with its ring made up of rings—makes its first appearance in the Simon patent. Its sheet iron component rings are insulated magnetically from each other. The Lake patent is simply the English version of one of the several Weston patents to which reference has already been made.

The laminated or divided iron core idea is shown in the following four British dynamo machine patents of the year 1878: No. 2003, May 18, H. J. Haddan; No. 3658, Sept. 17, J. H. Johnson; No. 4844, Nov. 27, I. L. Pulvermacher; No. 5139, Dec. 14, W. B. Brain.

The Haddan patent may be dismissed from further consideration by the statement that it is simply the English patent for the Brush machine. The Johnson patent describes the well-known and important De Meritens machine, the armature of which is composed of a brass ring around which are coils with soft iron segmental cores, separated by diamagnetic partitions, which cores are built up of a great many thin plates stamped out of sheet iron. The Pulvermacher dynamo consists of two horizontal and concentric cylinders built up of a number of soft iron rings bolted together; and in the Brain dynamo, the armature is composed of a ring made up of sheet iron or wire.

In 1879, I find but a single British patent requiring notice. This is a second patent granted to L. Simon, for the Shückert machine, No. 960, of March 11.

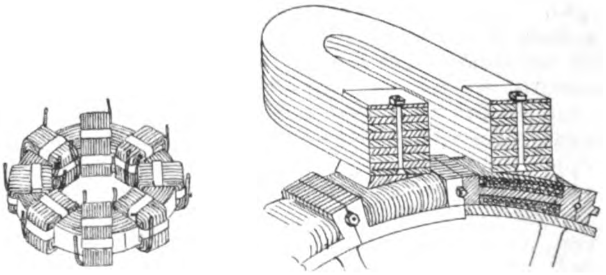
The armature core is a flat ring and is built up of several sheet iron discs magnetically insulated from one another.

In 1880, also, but one dynamo appears which conspicuously shows divided iron. This is the British patent on the Edison machine which has already been noticed in connection with its U. S. Patent. Our list of the British patents involving the feature of division closes with No. 253 of January 20, 1881, to Charles G. Gumpel; No. 3,362 of August 3, 1881, to John Hopkinson; and No. 5,665 of Dec. 24, 1881, to S. A. Varley, two of which are for dynamos, the other being for a self-induction coil.

Of these, the first shows among other things a dynamo armature which, the specification says, may be made "either in one solid piece or built up of sheet, wire, hoop or other convenient form of iron"; and one of the forms illustrated shows it as being constructed of a number of "iron rings *electrically insulated from* each other."

The Hopkinson patent is for a coil in which the counter E. M. F. of self-induction is used for purposes of regulation. Fig. 8 shows one of the patented forms of the coil. This form has a ring-shaped iron core, coiled from a ribbon of sheet or hoop iron, and having a layer of insulating material between the layers of iron. Coils of covered wire are slid over this ring. The patentee identifies the laminations of this core with the wires of other cores by saying: "Instead of an annulus of sheet iron, iron wire may be used, wound after the manner employed in the construction of the armature of the Gramme machine." By the same remark, he also identifies the relation of divided cores in dynamos, with divided cores in induction coils.

In the Varley patent the armature of a dynamo is made up of a number of bobbins. The bobbin cores are constructed of a series of thin plates of iron arranged side by side, magnetically insulated from one another by pieces of paper or other suitable insulating material placed between the plates.



FIGS. 8 AND 9.

French patents referring to the necessity of dividing the iron of armature cores are: No. 109,573, Sept. 11, 1875, Burgin; No. 120,649, Oct. 8, 1877, Gramme and d'Ivernois; No. 126,652, Sept. 23, 1878, Le Bailly; No. 127,385, Nov. 12, 1878, Bertin and Mersanne.

The Schückert machine, with its laminated ring is quite fully discussed in *Dingler's Polytechnisches Journal* (Vol. ccxxiii, p. 587, 1877) and in the *Telegraphic Journal*, (London, Vol. v, p. 105.) The latter periodical commenting upon the construction of its armature has to say: "Again, the iron ring is not in one massive piece, but in several ring discs, separated from each other by ebonite, pasteboard, or the like, the whole ring being held together by brass rivets. The object here is to hasten the disappearance of remanent magnetism in rapid change of the poles, and to obtain the maximum of magnetization." *The Journal of the Telegraph*, New York, also makes a similar note (Vol. x. June 1, 1877, p. 163).

The De Meritens machine was brought prominently before the public in 1878, and is well described in many publications of about that time. Its armature, Fig. 9, is a wheel made up of a number of segmental pieces each separately wound with the generating coils, and all being joined together by suitable bolts, yet magnetically insulated by interposed pieces of copper. Each of these segmental pieces is made up of thin plates of iron cut out and placed together to the number of 50, each one millimeter thick. This point, as well as its reason, is noted in *Telegraphic Journal*, London, (Vol. vi, Oct. 1, 1878, p. 397); *Electrician*, London, (Vol. ii, Dec. 7, 1878, p. 29); "Electrical Illumination," Dredge, (Vol. i, pp. 188–201) from which we take the figure; "Lighting by Electricity," a Blue Book published by the British House of Commons in 1879, p. 247; "Electric Lighting," Du Moncel, (London Translation 1882, p. 56); "The Electric Light and its Practical Applications," Paget Higgs, (London 1879, p. 113); and in many other works relating to the electric light, and to dynamo-electric machinery.

The *Journal of the Telegraph*, commenting on a United States patent granted for a telephone whose magnet-core was made up of small wires, refers to the works of Page and Sturgeon, and then adds :—"Ever since that time the magnets of induction apparatus have been constructed in this manner. Upon the same principle, the magnets of the printing instruments and relays used by the Gold and Stock Telegraph Company, have been for many years made with split cores, the advantage of so doing having been shown by the experiments of G. W. Dean of the Coast Survey, upon the transmission of longitude signals through repeaters ;" (C. S. Report 1865); (*Jour. of Tel.*, Vol. xi, Jan. 16, 1878, p. 21.)

Culley calls attention to the necessity for slitting metallic tubes surrounding electro-magnets, and metallic bobbins on which their coils are wound; and speaks of the advantages of grooving or slotting solid iron cores for electro-magnets, and of the use of fine insulated iron wires in cores; ("Handbook Practical Telegraphy," Seventh Edition. London, 1878, p. 76, and p. 100). Other accounts of the laminated Schückert ring armature may be found in Schellen's "Die Magnet: und Dynamo Elektrischen Maschinen," Köln, (1879, p. 141); *Telegraphic Journal*, (London, 1879, pp. 118–119); and Dredge, "Electric Illumination," (Vol. i, p. 299).

Cance in his dynamo also recognizes the value of the lamination principle. It is described by the *Telegraphic Journal* as being of the same general class as the Niaudet machine, each bobbin being "composed of a bar of soft iron formed of a number of iron wires, well annealed and very soft; on these are coiled two layers of insulated copper wire, and then a second wrapping of the same dimensions as those forming the core, etc.;" (*Telegraphic Journal*, London, Vol. viii, Oct. 15, 1880, p. 346).

On Feb. 26, 1879, Mr. E. A. Cowper read a paper on "The Writing Telegraph" before The Society of Telegraph Engineers, London, in which, referring to the receiving instrument he says :—"The stationary electromagnets are *laminated, being made of very thin iron plates, such as I employed in an electromagnetic machine used by my father to spin cotton on the lecture table at the Royal Institution in* 1838, *as such plates almost entirely do away with residuary magnetism.*" (*Jour. Soc. Tel. Engrs.* Vol. viii, 1879, p. 145).

Dredge mentions the lamination feature of the Siemens, Jürgensen, and Fein machines, ("Electrical Illumination," Vol. i, 1882, p. 282, p. 302 and p. 307).

For the sake of making this record as complete as possible, references to such other publications as are mentioned in articles which relate to this subject, but which themselves have not been accessible for personal examination, are here given.

They are: *Poggendorff's Annalen der Physik:* For 1836, Vol. xxxviii, pp. 417–444; 1839, Vol. xlviii pp. 95–106; 1841, Vol. liv, pp. 312 and 315; 1842, Vol. lvi, pp. 251–268 and 268–274; 1851, Vol. lxxxiv, pp. 181–213; 1854, Vol, xcii, pp. 220–237; Vol. xciv, p. 296; Vol. xcvii, p. 261.

Silliman's American Journal of Science and Art: For 1841, Vol. xl, p. 201.

Dingler's Polytechnisches Journal: For 1870, Vol. cxcvii, pp. 133–135.

SOME EXPERIMENTS WITH DISRUPTIVE DISCHARGES.

BY

Alexander Jay Wurts.

A circular recently sent to me, describing a new spark-gap arrester containing a coil in the discharge circuit, makes the two following statements. First: "When a statical discharge takes place and the line is struck, the lightning, of course, seeks the most direct outlet to earth, and that is through the arrester, for the resistance of this whole apparatus from line binding post to ground is less than one-sixth ($\frac{1}{6}$) of an ohm." The second statement is: "It might be thought that this coil offers some resistance to the passage of the lightning, but it does not offer any more than a straight conductor of the same cross section and length, for the core, or armature, is not inside the winding until after the passage of the lightning. There is no self-induction in this arrester, as some might suppose, for there is no current flowing through the coil until after the passage of the lightning, and the passage of the lightning is instantaneous and it cannot produce induction to hinder its own passage." This arrester is also described in The Electrical Engineer for Dec. 14, 1892.

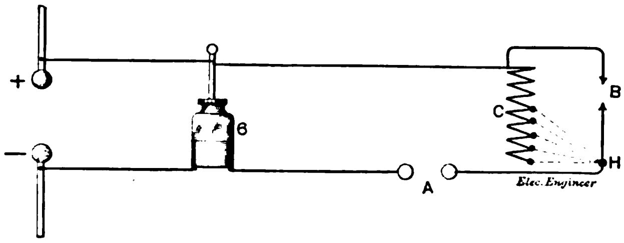
The first of these two statements, in speaking of the ohmic resistance from line to ground being less than one-sixth of an ohm, can hardly be correct, for if even the smallest spark-gap were included, the resistance would then be practically infinite. If, however, it is only the resistance of the coil that is considered, then, either the wire of which the coil is made must be very fine (assuming that it is made of copper) or if it were even as large as No. 7, its length would be considerable, for the resistance of 1,000 feet of No. 7 copper wire is .150 of an ohm. If this coil is four (4) inches in diameter and contains 1,000 feet of wire it would then consist of about 1,000 turns. I will presently describe some interesting experiments that I have made, and the reader will then judge for himself whether this arrester offers any considerable resistance to the passage of disruptive discharges such as occur during thunder storms across the spark-gap of an arrester when connected to overhead wires.

The second statement is well covered in Mr. Wm. Turbayne's article, published in The Electrical Engineer for Dec. 28, 1892. Mr. Turbayne has, however, made statements without giving the practical illustrations which are so necessary in order to carry conviction to the vast majority of men particularly interested in this subject, and who, although fairly well posted in the fundamental principles of electricity, are wholly ignorant of the more intricate problems, seldom studied outside of the laboratory. The experiments which I am about to describe are intended to illustrate facts in a simple, comprehensive manner, and without the technicalities and formulæ which so often accompany matter of this kind and draw but a passing glance from the "practical man."

The apparatus and connections used are clearly shown in the accompanying figure, in which "+" and "—" represent the two terminals of a Toepler-Holtz influence machine. "6" is a battery of six one-half gallon Leyden jars. A is a $\frac{12}{32}$ inch spark-gap between two brass ball electrodes, each $\frac{1}{2}$ inch in diameter. C is a coil of wire, the material and dimensions of which are changed according to circumstances. The specifications for this coil will be given for each test. B is a spark-gap, which may be adjusted at pleasure. It is connected in shunt to coil C and consists of blunt points made from $\frac{1}{2}$ inch brass rod.

The object of the influence machine, "+" and "—," is to statically charge the battery of jars, "6". The object of the jars is to accumulate a sufficient quantity of static electricity to produce a violent disruptive discharge. The object of the spark-gap A is to cause a disruptive discharge to take place through the coil C, or across the gap B, as the case may be. The object of the gap B is to determine the relative resistance offered by the coil C to a given disruptive discharge, by adjusting the distance between the confronting points till the discharge shall just leap the gap, in preference to passing through the coil. The object of changing the dimensions and material of coil C will be understood as we proceed. The object of each test is to determine the length of spark-gap at B that a disruptive discharge, such as would occur at A, will rather leap, than pass through a coil placed at C. In other words, the length of the spark-gap B, as given in the following table, is a comparative measure of the resistance offered by the coil to the disruptive discharge.

The first coil placed at C was made of No. 14 German silver wire. It was $\frac{9}{16}$ inch in diameter and contained no core. The number of turns included by the circuit B was varied by connecting the point H to different points in the coil. The following are the results obtained: The numbers under column C indicate the number of turns used in coil C; the numbers under columns B (1) and B (2) indicate the number of thirty-seconds of an inch that the disruptive discharge would prefer to jump rather than pass through the specified number of turns in coil C. From the connections indicated it will be evident that the discharge will have a choice between the path C and the path B.



C	B (1). German silver.	B (2) Copper.
82	11.	14.
77	10.75	13.5
72	10.50	13.
67	10.25	12.5
62	9.75	11.75
57	9.50	11.25
52	9.25	10.75
47	8.75	10.25
42	8.25	9.75
37	7.75	9.
32	6.75	8.
27	6.25	7.25
22	5.25	6.25
17	4.25	5.
12	3.25	3.25
7	1.50	1.75
2	.50	.50

Thus it will be noticed that the disruptive discharge, rather than pass through 82 turns of this German silver wire coil containing no core, will jump about $\frac{1}{3}$ of an inch. This coil being made of German silver had a high ohmic resistance compared with a similar coil made of copper. But this resistance plays no appreciable part in impeding the passage of the discharge, as will seen from the following.

The next test was made with a copper coil of the same sized wire as the German silver, and was supposed to have the same dimensions; as a matter of fact, however, it was a shade larger in diameter. The results obtained with the copper coil are given in column "B (2)."

It will thus be seen that the copper coil, in spite of its low ohmic resistance, offered even a higher resistance to the passage of the discharge than did the German silver coil. But this increased resistance is no doubt partly due to the slightly increased diameter of the copper coil over that of the German silver coil; for, the greater the diameter of a coil the greater will be the resistance offered to the passage of a disruptive discharge. To demonstrate this fact, I connected at C a coil 8 inches in diameter, consisting of 19 turns of No. 4 copper wire, and found the "B" spark to be 21.

Not having the dimensions of the coil in the above-mentioned arrester, I am unable to give the comparative resistance that this arrester will offer to the passage of a disruptive discharge. Assuming, however, that the coil is 2 inches in diameter and contains only 100 turns, it will be evident from the above figures that the arrester will offer a very difficult path to the passage of disruptive discharges. In view of this fact the possibility of fine adjustment in the spark gap, also claimed for the arrester, amounts to nothing at all.

Now an increase in the length of the spark gap at A will cause the battery of jars to discharge at a greater difference of potential; the amount of charge will be greater, and consequently that of the discharge. With every increase in the intensity of the discharge at A, there is considerable increase in the B value for any given coil C. It is, therefore, fair to assume that the B values found in these experiments will be considerably larger when the conditions are such as are usually experienced during thunder storms.

Having thus far illustrated facts, it will now be proper to explain that a disruptive discharge is oscillatory in its character; that is, it is similar to an alternating current of very high frequency, and it consequently meets with self-induction in its passage through wires. The frequency developed in a disruptive discharge is, however, vastly greater than that developed by an alternating current dynamo, and the inductive resistance, being proportional to the frequency, is also enormously greater; this fact, therefore, accounts for the high resistance offered to discharges of this kind by even a few turns of large copper wire.

The inventor of the above mentioned arrester is also mistaken in his assumption that the coil of the arrester offers less resistance when the iron core is out than when it is in, for the oscillations of the discharge are too rapid to affect the iron. Consequently, there is no increase in the self induction when the iron is in, or, if there is, the effect is so insignificant that it is more than compensated for in the Foucault currents set up in the core. These Foucault currents will of course act as a closed secondary and tend to reduce the inductive resistance of the coil. In fact, with the above mentioned copper coil made of No. 4 wire, and with which B was found to have a value 21, the introduction of a bundle of iron wires into the interior of the coil caused the resistance to decrease and gave a B spark equal to 17.

In order to demonstrate that there was no perceptible magnetic action due to the presence of the iron core, in other words, that the same results would be obtained with a non-magnetic metal, I coated the inside of the coil with tin foil, and on again measuring B found it to be 17, as before. The tin foil formed a secondary to the coil and therefore reduced its inductive resistance. If the ends of the tin foil coating made poor contact, a brilliant spark would appear at that point each time a discharge passed through the coil, and a hole was burned in the foil. The Foucault currents in the bundle of iron wires manifested themselves by a beautiful display of scintillating sparks between the wires of which the bundle was made. Upon repeatedly passing the discharge through the coil, however, the scintillating sparks gradually decreased, but at once reappeared when the iron wires were connected to earth. A slight shock was felt on touching them with the hand. There is thus static as well as dynamic induction between the coil and its metal core.

It is curious to note that the coil described in connection with the above mentioned arrester as offering no resistance to the passage of the discharge forms one of the principal features in the "Tank Arrester," (see THE ELECTRICAL ENGINEER, Nov. 16, 1892) for preventing disruptive discharges from reaching the generator; in fact, such a device is commonly called a "choke coil."

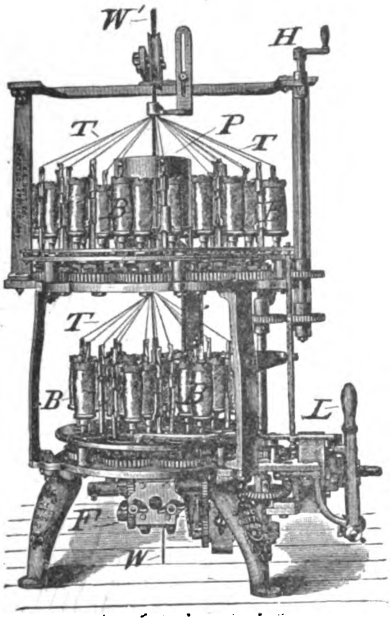
In a subsequent article I shall continue these practical illustrations, showing the impedance offered by comparatively straight wires; the necessity for using a large number of line arresters, in order to form an efficient protection for electric circuits; also the best means and materials for making lightning arrester connections to earth.

INSULATED ELECTRIC CONDUCTORS.—XVIII.

BY

James Bowstead Williams M.A.C.

Weatherproof Wires.—The simplest form of a painted weatherproof wire is one having a covering or dielectric formed of one or two braids saturated with paint; and because the covering is apparently so simple it is usually one of the poorest made. The principal reason for this is that the common process of manufacturing such coverings consists in (1) forming two braids on the wire, and (2) soaking the braids in paint. This work, on account of its apparent simplicity, is often entrusted to inexperienced hands whose duty it is to see that the braiders work properly and that the braided coverings go through paint; that being done, their responsibility and interest in the matter are at an end. Weatherproof wires, if properly made, will do good service, but their production requires care, and a knowledge of insulating material. The process of manufacture of a good weatherproof wire involves several steps which will be considered in the proper place.



DOUBLE BRAIDING AND INSULATING MACHINE.

To illustrate the method of manufacturing any kind of painted wire, that one mentioned at the beginning of this article will be selected. For this work a braider such as is shown will be required. In the engraving, W represents the naked wire; W' the same wire after it has been covered with two braids; T - - - T are the separate threads or yarns, wound on the bobbins, B - - - B, and which are united to form the braids; P is a vessel containing paint, and provided with a stuffing box at the lower end, through which the wire passes and which prevents escape of the paint; H is a handle for operating the braider by hand while making adjustments, threading the bobbins, etc.; L is the mechanism for throwing the machine in and out of gear; and F is the feeding device for the wire.

The dielectric is formed in the following manner: The wire W, previously straightened and reeled, is drawn off the reel by the action of the feed F, which consists of two grooved adjustable rolls, having their grooves scored so that they will grasp the wire without slipping, which revolve in opposite directions by means of suitable gearing. The feed then pushes the wire upwards, and the lower set of bobbins throws the first braid consisting of 16 strands, upon the wire. The wire, thus covered, passes through the paint in P when the first braid is soaked with the paint. Continuing upwards, the soaked braided layer is covered with a second braid, formed of 24 strands, by the upper set of bobbins. After the wire has received its second braid it is taken off on reels. The push-up feed is necessary for this kind of work, for if the ordinary take-up device—such as is shown on the braiders in No. XV of this serial—were used the wet braided layers would become flattened or lose their circular form by pressure on the wheel around which the wire is wrapped and which *pulls* the wire through the machine. Even after W' leaves the machine it must be carefully drawn along and reeled in order to avoid compressing the braids.

If we examine W' we will find that the inner braid is apparently saturated with paint and that some of the paint which adheres to this braid as it leaves the vessel has entered the interstices of the outer braid and has also stained, wholly or in part, the fibre. As it is practically impossible to complete the saturation of the covering in a machine like that shown, the outer layer—supposing that the inner layer is fully saturated and the spaces therein filled—must be finished by passing W' through some kind of liquified insulating material, whether paint or a melted compound. This may be done immediately after it leaves the braider, or the wire may be laid aside until the inner layer becomes dry and then finished. This subsequent soaking is often advantageous, for if there are vacant spaces left in the inner layer after it has hardened, the liquid material, besides completing the outer layer, may enter into and fill these spaces. At any rate, it can be *made* to do so.

The foregoing description is that of a process of manufacturing the simplest kind of painted weatherproof wire which is extensively used; what its disadvantages are will be mentioned later.

Painted dielectrics can be formed in a variety of ways. For example, the inner layer may have for its body a wrapping or tape of fibrous material and the outer a braid, the whole being saturated with one kind of paint; or the covering may consist of several braids, each braid being saturated with the same or a different kind of paint. Theoretically, there is no limit to the number of decks—each deck forms a separate braid—and paint vessels a braider may have, but practically there is, and the limit of usefulness is reached in a triple deck machine; for the time consumed in repairing broken threads, threading the machine, etc., barely compensates for the increased number of layers.

ELECTRIC POWER TRANSMISSION AT NEUCHATEL, SWITZERLAND.

THE department of public works of the city of Neuchâtel has instituted an international competition for designs for an electric transmission plant by means of which the water power at Pré aux Clées is to be made available at Neuchâtel, some 5⅛ miles distant. Turbines and generators to be installed at Pré aux Clées, the minimum water power available being 952 h. p., and the maximum 2,800 h. p. The competition was closed on Jan. 15, 1893. The prizes offered for the best three designs were 5,000, 4,000 and 3,000 francs. The judges were Dr. Hirsch, of the Neuchâtel Observatory, chairman; Prof. H. F. Weber, of Zurich; Prof. Colombo, of Milan; Oscar von Miller, of Munich, and R. W. Picou, of Paris.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed, and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 208 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can 'entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XV. NEW YORK, FEBRUARY 15, 1893. No. 250.

THE DAY OF ELEVATED ELECTRIC RAILROADS.

ENGLAND may be slow in the general matter of electric traction, but she has certainly set us an excellent example in two new fields, namely those of elevated electric railroads and of underground railroads. We have one or two quasi elevated electric roads in this country, such as that at Baltimore recently illustrated in THE ELECTRICAL ENGINEER, but we have no road like the one just opened at Liverpool and very fully treated in our Electric Railway Department this week. At present, underground electric roads do not appear to be wanted very badly by the American public, but if we are to have more elevated roads, it is certainly desirable that they should be operated electrically. The work in Liverpool differs in many ways from that which has been done in this country with the help of the trolley, and we are personally inclined to the opinion that some of our largest trolley roads as well as their passengers, would be better off, if resort had been made in the first instance to an elevated track. It stands to reason that no very high rate of speed can be permitted on the street surface. The result is that while the motor cars would easily make 15 or 20 miles an hour, they are necessarily geared down to make only 6 or 8; and hence many of the advantages of electric traction are at once sacrificed. On this Liverpool road, the schedule gives a maximum of 26 miles an hour, showing that "rapid transit" there is a reality and not something to yearn for. One thing deserves notice, however, and that is that a well built trolley road is vastly prettier and infinitely less obstructive than the Liverpool elevated road or any other elevated road that has been built. Not only so, but while in New York our elevated roads do let down a little sunlight into the streets, in Liverpool the road bed is a solid roof, with consequent darkening of the thoroughfare below.

The great gain and main advantage, after all, is in the adoption of electricity, doing away with steam, grit, dust, gas escape, oil drippings, etc., and minimizing the noise. Our American standard of 500 volts has been adopted, but there might, we think, have been an additional economy in conductors, and other elements, by the use of a higher potential, say up to 750 or even 1,000 volts. Still the Liverpuddlians are on the absolutely safe side, and that means everything in England. The work about the road and rolling stock is evidently substantial, and all the latest improvements have been adopted, including incandescents for the cars. As a whole, the road embodies many suggestions for New York, where, as in every other large city in the Union, rapid transit facilities are sadly short of the mark and far behind the age.

LONG ELECTRIC ROADS.

IN view of the fact that many of the electric street railway systems have grown to a length of over 100 miles of track, there is nothing very wonderful in the now thick-coming announcements of "long distance" roads extending across country hitherto served poorly by steam railroad or else left entirely without modern transportation facilities. But these announcements are certainly serving to attract public attention to the subject of electric traction, and indicate how thoroughly enterprising capitalists have been satisfied as to the possibilities of this comparatively new field. Last week saw the completion by Mr. J. D. Crimmins, who represents New York financiers, of arrangements by which 140 miles of road in New Jersey will be brought together in a great network reaching from the Hudson shore to the banks of the Rahway and Raritan. There is no good reason why the branches remote from New York should not in the very near future touch and interloop with a similar network spreading northward from Philadelphia. When this is done another step can be taken by filling in the reticulations, so that wherever it is worth while to have a highway, it will be an electric road. So far from being a detriment to the steam roads, these trolley lines must enormously increase their business by stimulating and populating the whole region. Similar work is already being done in New England, Ohio, Pennsylvania, Maryland, and other States.

The Berliner Patent.

THE news that the Government itself is attacking the validity of the Berliner telephone patent should not cause any great surprise. Such procedure only puts into the form of action the feeling on the part of the public and of a large section of the electrical profession that monopolies must not be perpetuated by any such means and contrivances as led to the delay in the issuance of that and kindred patents. The American Bell Telephone Company probably considered itself within its legal rights in its adoption of the policy that gives it so broad a patent at so late a day, but the Government is of contrary opinion, and is apparently convinced also that the worst thing which could happen to inventors and the patent system is the indefinite prolongation of monopolies of this kind in this way.

ELECTRIC RAILWAY DEPARTMENT.

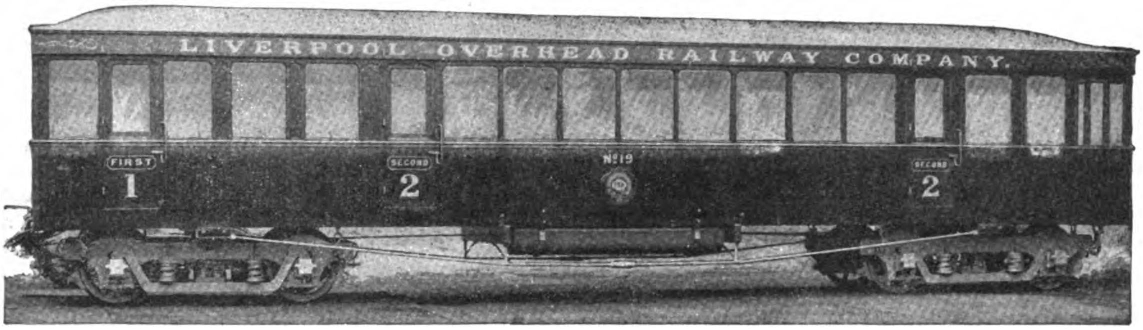
THE LIVERPOOL ELEVATED ELECTRIC RAILWAY.

BY

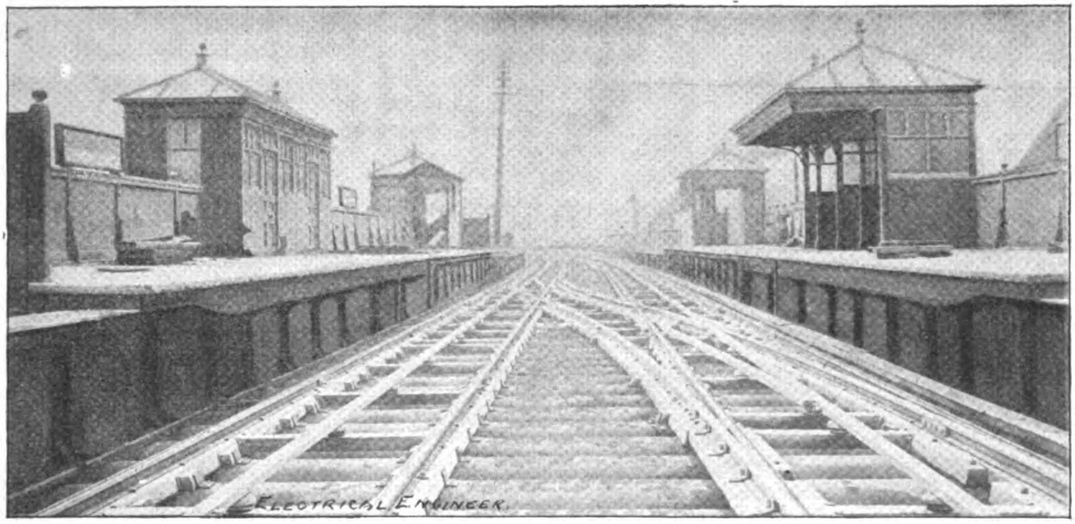
H. Scholey

I.

It can be claimed with some degree of confidence that there is a real movement in the direction of electric traction in England. Not only are there several schemes proposed which will no doubt result in something useful, but there have been recently completed two schemes which will no doubt exercise a marked effect on electric traction generally. The Liverpool Railway is an important departure in railway enterprise in England for two reasons: It is the first elevated road and the largest line equipped with electric motors.



Passenger Coach, Liverpool Elevated Electric Railway.



View of Track and Stations, Liverpool Elevated Electric Railway.

This line, which is practically ready for traffic traverses the entire length of the Liverpool Docks, a distance of about six miles, but there is nothing to prevent an extension, and, indeed, the shareholders of the concern have already been asked to sanction the raising of fresh capital for the purpose of carrying the line some three miles further. The passenger traffic along the route of the Docks is enormous and as the railway will supersede the old-fashioned 'buses there is every reason to expect that the line will be a great commercial success.

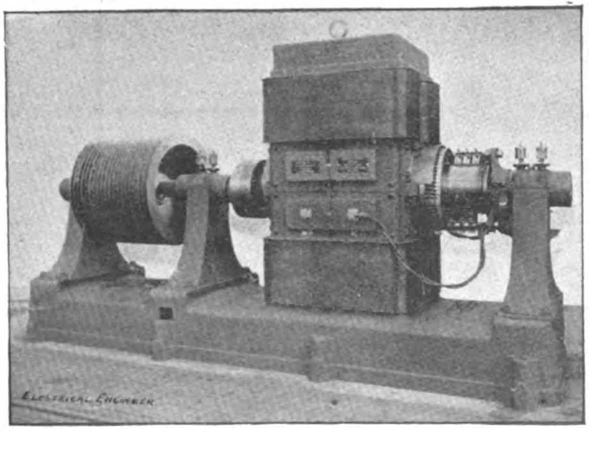
An elevated railway in Liverpool was proposed as long ago as 1852 when Mr. John Grantham proposed a scheme for a high level railway to run from the Mersey Forge to the land opposite the Huskisson Dock, a distance of about four miles. The scheme was well thought out and possessed some remarkable features. It was proprosed to use six lines, two to be used for passenger traffic, two for goods traffic, and the two nearest the docks for sidings on which the goods could be loaded and unloaded. The scheme was much thought of and many of the prominent men in Liverpool were ardent supporters of it. The Dock Board, however, refused to consider the matter seriously, and although Mr. Grantham prepared most exhaustive figures nothing was done. However, in 1877, at a meeting of the Dock Board one of the members drew attention to the delays and inconveniences arising from the increased traffic and proposed that the Board should consider the expediency of erecting an overhead steam tramway for the purpose of conveying passenger and other traffic. A scheme was then laid before the Board for a single line railway estimated to cost £150,000. After much consideration this scheme was abandoned and nothing was done for a year or two. In 1880, however, the subject came up again and after much difficulty the Dock Board secured a bill from Parliament which gave them powers to build a railway. This bill was transferred to the company which had been formed to carry out the scheme, the Liverpool Overhead Railway Company. The engineers are Sir Douglas Fox and Mr. Greathead, to the latter of whom I am indebted for many of the following details.

II.

The railway is composed almost entirely of wrought iron. With the exception of a short length, where the line passes under some coal sidings, the railway is overhead and for the most part just over the lines of the original Dock Railway, which is upon the surface. The latter railway serves for the distribution of goods by horse traction and has been used by passenger omnibuses with specially constructed wheels to enable them to leave the track when necessary. The omnibuses will now be dispensed with, for the railway will afford a means of transit at least three times as rapid. The Dock Railway will then be available exclusively for goods.

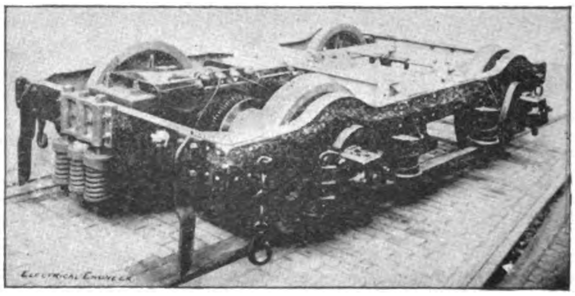
The overhead railway consists generally of plate iron girders supported upon channel iron columns and carrying an iron flooring upon which the permanent way is laid direct, without the usual intervening ballast. The normal spans are 50 feet, but there are some of 100 feet with bowstring girders and others of special construction for opening and affording a passage to the docks for exceptionally bulky goods, such as marine boilers, etc. Thus there is a tilting bridge near the Sandown Dock and a swing bridge of novel construction and worked hydraulically, crossing the entrance to the Stanley Dock. This is the only dock entrance crossed by the railway, the other docks being nearer the river.

The columns are grouted into cast iron sockets bedded in and bolted to masses of concrete forming the foundations. With the exception of some half dozen spans the line has been constructed without the use of scaffolding and with very little interference with the traffic, either of the docks or of the streets. This important end was attained by adopting a construction which admitted of each span and its flooring being put together at one end and transported as a whole over the already completed portion of the railway. A depot was established at the north end of the railway where the flooring was constructed and to the main girders put together. The whole span was then raised by jacks. A steam trolley with wheels running upon the two rails nearest the main girders (and thus having a gauge of 16 feet) was run under the span, which, being lowered upon the trolley, was carried by it at such a level as to clear the main girders to the southern end of the structure. Arrived at this point the span was slung upon a movable gantry and deposited by it upon the columns prepared to receive it. In this manner span after span was added, as many as 12 being placed in a week, representing a length of 600 feet of railway.



GENERATOR, LIVERPOOL ELEVATED ELECTRIC RAILWAY.

The decking is of arched plates, finishing to 2 feet 6 inches wide and 15 inches deep, made water tight by asphalt placed in the V channel between the arches. This form of flooring (known as Hobson's arch-plate system) first used on this railway, is being extensively used elsewhere. It is for its weight of great strength and stiffness and is readily made water-tight. The flooring is made of ordinary iron plates and tees. The plates are 46 inches wide by $\frac{5}{16}$ inch thick and vary in length from 22 to 27 feet. The tees are $4\frac{1}{2} \times 3\frac{1}{2} \times \frac{7}{16}$ inches section.



MOTOR TRUCK, LIVERPOOL ELEVATED ELECTRIC RAILWAY.

The construction of the decking is somewhat as follows: The flat plates are sheared to exact length and width. Six of them are heated at one time to a cherry red heat; they are then separately placed endwise in a hydraulic press which bends them to the required shape. After cooling upon a gird or frame where they are tightly held to prevent change of form, they are taken to a multiple drilling machine which drills the requisite rivet holes (about 200) in two operations and in 15 minutes. After the end angle irons for attachment to the main girders are added, the decking is completed by rivetting mechanically the curved plates to the T-irons forming the lower member. These combined operations are performed at the rate of 40 to 45 plates per day.

There are 15 stations on the line which are built on iron girders and columns, the platforms being about 150 feet in length by 12 feet wide and are three feet above the level of the rails. Access to the platforms is gained from the street level by four staircases at the more important stations and on each platform a waiting shed is provided with pay offices and turnstiles. An extensive carriage shed is erected near the Hornby Docks with five lines of rails running through at the same rail level as the main structure of the railway and on the ground floor is the repairing shop to be equipped with the necessary tools.

III.

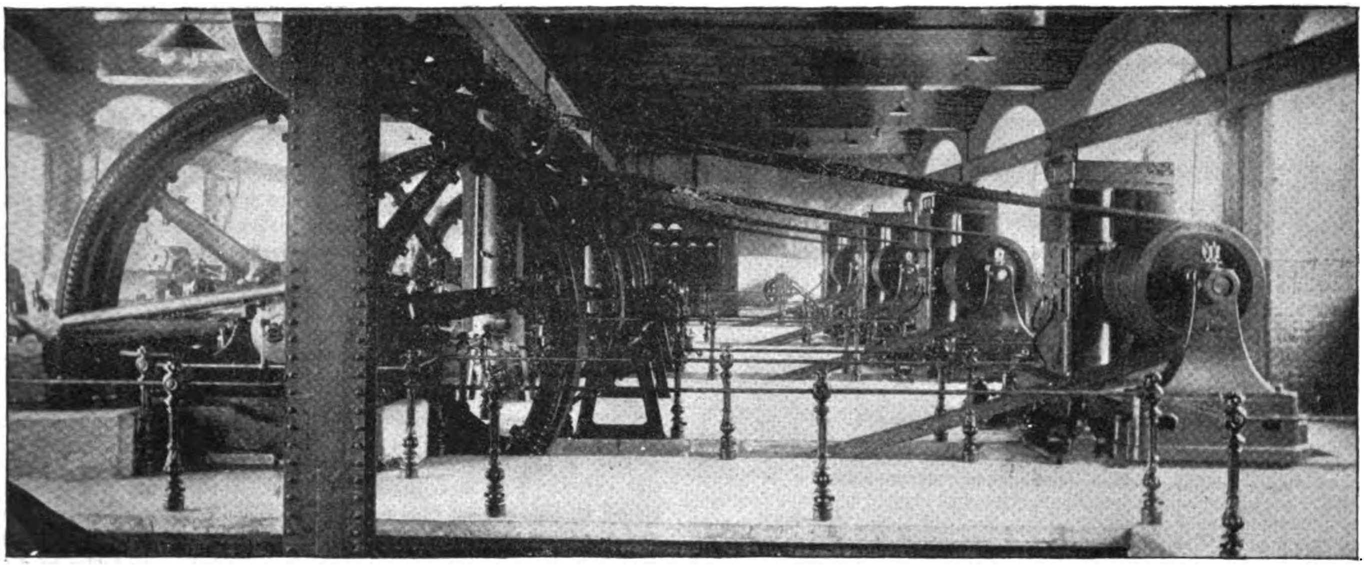
The permanent way is of a novel construction. Longitudinal sleepers resting directly upon and keyed to the arched decking support the rails and the electric conductor.

The conductor, consisting of a steel channel, is carried the whole length of both up and down lines between the ordinary rails, the latter forming the return circuit. The steel channel is carried upon porcelain insulators supported by cross timbers between the longitudinal sleepers. The surface of the steel channel, forming the centre conductor, is $\frac{7}{8}$ inch higher than the top of the ordinary rails. At the cross-over points the conductor is bent so as to run parallel for a short distance on each side of the ordinary rails, but leaving ample clearance to prevent arcing across.

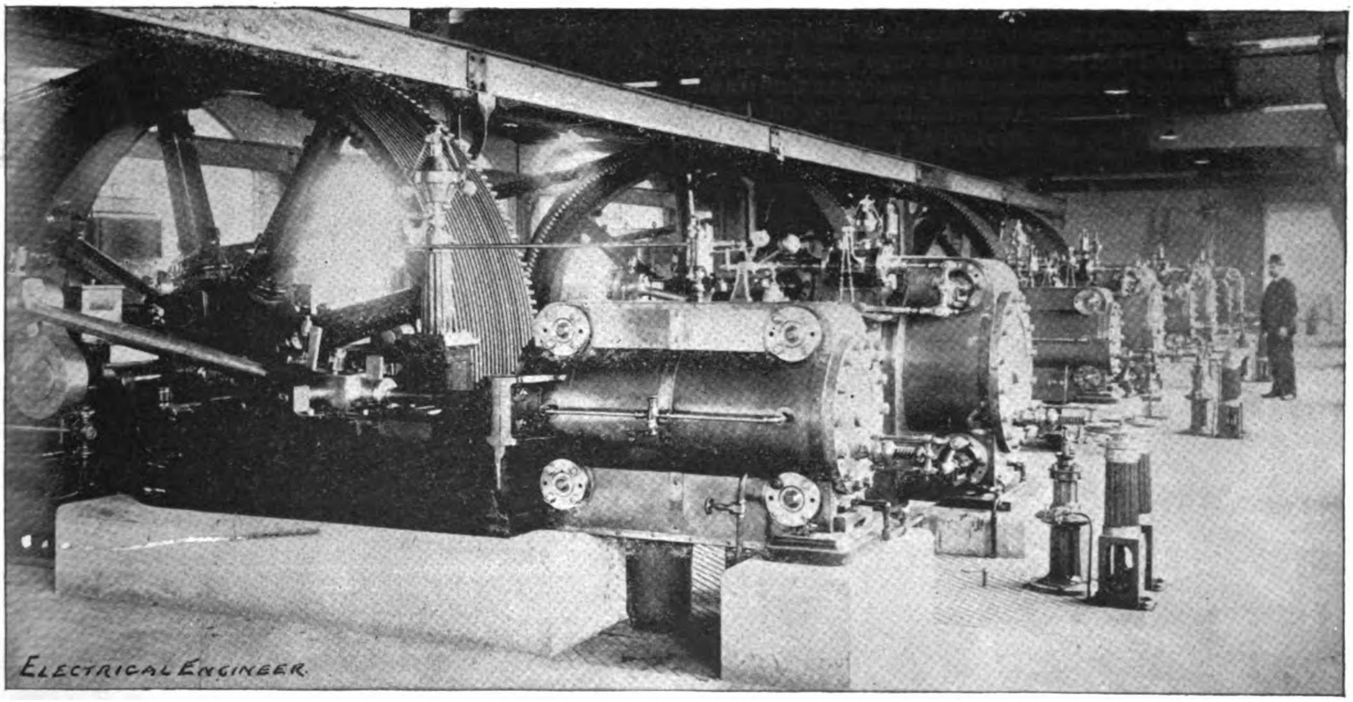
Timmis' automatic signals are to be used which will be operated electrically by the trains, thus doing away with signalmen.

IV.

The generating station occupies a position close to the structure and approximately in the centre of its length. In this are six Lancashire boilers, 30 feet by 8 feet, constructed for a working pressure of 120 lbs. per sq. inch, fired by Vicars' mechanical stokers, the coal supply being drawn from hoppers overhead into which the trucks on the existing coal railway are emptied. Coal is supplied to the various boilers by means of a conveyor. Green's fuel economizer consisting of 384 pipes is used.



DYNAMO ROOM, LIVERPOOL ELEVATED ELECTRIC RAILWAY.



ENGINE ROOM, LIVERPOOL ELEVATED ELECTRIC RAILWAY.

There are four horizontal, coupled compound engines, each capable of indicating 400 h. p. with 120 lbs. steam pressure at 100 revolutions per minute. The cylinders are 15½ inches and 31 inches diameter, by 36 inches stroke. Corliss valves are fitted to all the cylinders. The fly-wheels are 14 feet in diameter, grooved for 19 1½-inch diameter ropes.

An independent condensing arrangement is used, divided into two units, each capable of condensing steam from three of the main engines running under full load. The condensing water is taken from the dock adjoining the generating station and passes through brass tubes. The air and circulating (centrifugal) pumps are driven by small compound vertical engines having Ferguson's patent triangular connecting rods with cylinders 7½ inches by 15 inches diameter, 12 inch stroke. The auxiliary plant consists of two pumping engines for boiler feed, each capable of supplying four boilers; one engine for driving stoker and conveyor, 10 h. p., and two small engines for working the scrapers on the economizers.

All the steam and feed pipes are arranged to give a duplicate service between the boilers, engines and pumps. Arrangements are also made so that the engines may exhaust into the atmosphere in case of water not being obtainable at any time for condensing.

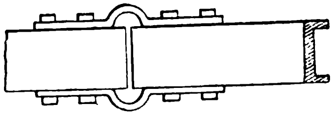
Cross Timber Supporting Conductor

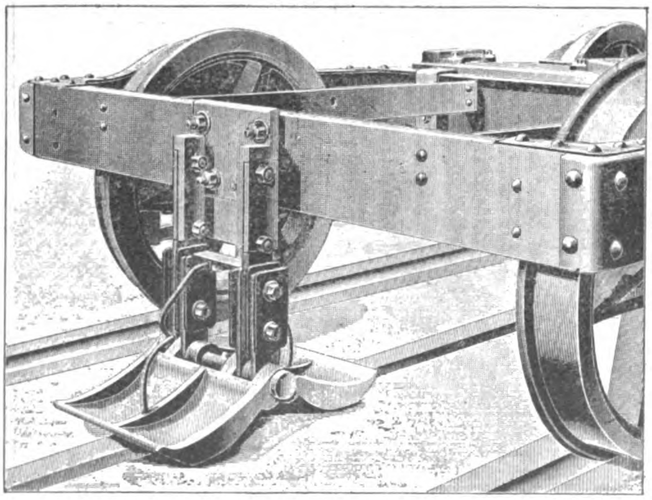


Copper Connections of Conductor Lengths

DETAILS OF STEEL CHANNEL CONDUCTOR AND INSULATOR.

V.

The dynamos are four Elwell-Parker shunt wound machines, each giving an output of 475 amperes at 500 volts at 409 revolutions per minute. The magnets are of the double horse-shoe type fixed vertically, divided on the horizontal centre line so that the top half can be readily lifted off to allow of examination or removal of the armature. A pulley is carried between two bearings which, when a coupling is inserted between the pulley and armature shafts allows the latter to be taken out without taking off ropes, dismounting the pulley, or interfering with the set of the bearings.



CURRENT COLLECTOR, ATTACHED TO MOTOR TRUCK.

Each dynamo is coupled up through an ammeter to a double-pole automatic magnetic cut-out, which also answers the purpose of a main switch. All the machines couple in parallel on to omnibus bars from which the current is taken by underground armored cables to the conductors on the line, a larger automatic magnetic cut-out being inserted, carrying the whole of the current. Multiple contact switches and resistance coils in the shunt circuit are employed for regulating the E. M. F. of the machines.

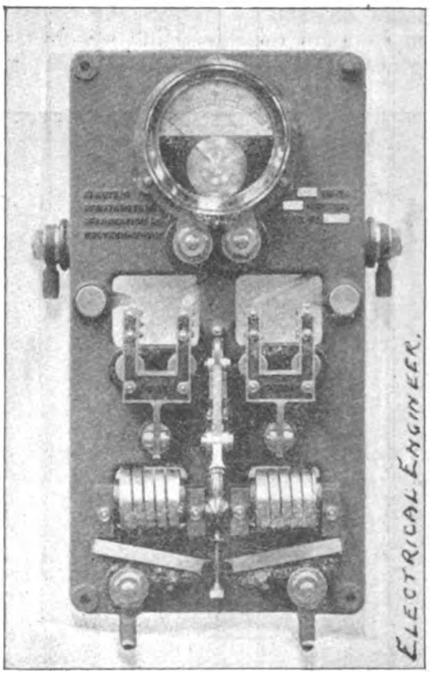
VI.

The length of the carriages over end pillars is 45 feet, the width over side pillars being 8 feet 6 inches. The carriages are mounted on two 4-wheeled bogies, 32 feet apart on centres, and one of which carries a motor. The wheel base of bogies is 7 feet, the wheels being 2 feet 9 inches diameter. They carry 57 passengers, 16 first class and 41 second class. Two carriages form a train and as each is fitted at one end with a driver's box and necessary switch and brake gear for controlling the work there is no shunting at the terminal stations, the driver changing ends. The gangway between the two cars gives a clear passage through for the guard. A train loaded with passengers will weigh about 40 tons. The motors on each train are on the leading and trailing bogies. Six incandescent lamps light each carriage, supplied with current from the centre conductor the same as the motors.

VII.

The armatures of the motors are mounted directly upon the axles. Ten revolutions of the axle per minute gives a speed to the car of one mile per hour. The maximum speed necessary to do the journey in the time specified is approximately 26 miles per hour, or 260 revolutions of the motor per minute.

The motors are series wound and when tested with a brake gave the following torque effects on the rim of the wheels (2 feet 9 inches diameter) with respective currents given below, when at rest :



AUTOMATIC MAGNETIC CUT-OUT.

30 amperes	......	170 lbs.
40 "	......	300 "
50 "	......	450 "
60 "	......	650 "
80 "	......	1,060 "

The current is collected from the surface of the steel channel by means of cast iron shoes loosely hinged to insulated iron strips carried by the bogies. The shoes are made much wider than the conductor so as to stretch across at the cross-over roads from the conductor on the one side to the conductor on the other side of the ordinary rails. A collector is fitted to each motor bogie.

The carriages are fitted with Westinghouse brakes worked by compressed air stored in receivers carried under the carriages, these being charged by an air compressing plant fixed at the terminal station at the north end of the line. Hand screw brakes are also provided.

VIII.

The journey from one end of the line to the other will be completed in 30 minutes which includes a ½ minute stop at all stations. The rolling stock in the first instance provides for a five minutes service, though ultimately trains will be dispatched every three minutes. The present generating plant will allow of this being done. There are fairly sharp curves on the lines, the maximum being 400 feet radius. The maximum grade for a short distance is 1 in 40. The total cost of the railway including equipment will be about £85,000 per mile.

The electrical work has been carried out by Mr. Thomas Parker for the Electrical Construction Corporation.

STREET RAILWAY FIGURES IN MASSACHUSETTS.

THE various street railways in Massachusetts have entirely eclipsed the steam roads in the passenger traffic, showing a most remarkable increase the past year. The report of the Railroad Commissioners of the State shows a total mileage of street roads of 814.36 miles, and of this over 60 per cent. is now equipped with electric power with prospects of a much larger percentage using this same means of propulsion. A total of 193,760,783 passengers was carried during 1892, which exceeded the passenger traffic on the steam roads by 82,845,329.

The Commissioners further state that so far, no legislation has been enacted which takes note of the change that the street railway has undergone, with the substitution of electric power, a transformation by which it bears a closer resemblance in essential respects to the steam railroad than to the horse railway. The electric roads at present so far as being regulated at all are regulated only by a code of laws which was framed in reference to the original system of horse transportation. The Commission urges the necessity of laws being enacted which shall put the electric roads on a similar footing with steam roads in regard to grade crossings and other matters for the public safety.

The total amount of property and assets of the companies is $39,448,838; surplus over all liabilities, $855,379. The total average cost for each mile of railway track is $47,356. Whole number of cars owned, 3,659; increase, 165; number of employes, 7,157; increase, 708; total number of passengers carried, 193,760,783; increase, 17,670,594: gross income for year, $9,817,537; increase, $916,413; gross expenses, $7.461,224; increase, $338,931; net income, $2,356,312; increase, $577,482; average sum received for the conveyance of a passenger, 5.07 cents; average cost of carrying a passenger, 3.85 cents; whole amount of dividends paid, $1,582,697, an average of 6 72 per cent. on the total amount of capital stock, as against 5.63 per cent. the previous year. Total number of accidents, 610, of which 26 were fatal.

PROPOSED CONNECTICUT STREET RAILWAY COMMISSION.

SENATOR Root has introduced an Electrical Street Railway bill in the Connecticut state senate, empowering the Governor to appoint a street railway commission, to consist of three members, whose terms shall be one, two and three years respectively from July 1, 1893. One member of the commission shall be a lawyer, another an electrical engineer, and the third a business man. The governor shall have power to designate the chairman of the commission, who shall receive a salary of $3,000 per annum. The other members shall have a salary of $2,500 yearly; and no member shall have any personal interest in any street railway, or in the manufacture of any electrical appliances or apparatus for the use of such railways. The expense of the commission shall be met by a tax laid upon the gross earnings of the electric railway companies of the state. Wherever an electric road shall already be in operation or existence, no other company shall interfere in any manner without first applying to the mayor, and board of aldermen and councilmen of cities and selectmen in towns, who shall call a hearing of parties interested. From the decision of these bodies any dissatisfied persons shall have the right of appeal to the street railroad commission, whose decision in the matter shall be final, and from which there shall be no appeal.

THE LAKE STREET ELECTRIC ROAD IN CHICAGO.

THE Directors have been given full power to close a contract with the construction company that is to build, equip, and open for traffic the entire seven and a half miles of road during the present year. The old company gave up its control, finally and completely, and dating from February 2, the Eastern capitalists, who own practically nine-tenths of the issued stock in the new company, will dominate affairs.

The stockholders further agreed to increase the capital stock of the company in the near future from $5,000,000 to $10,000,000. They also empowered the directors to issue $6,500,000 in first mortgage bonds, payable in gold and bearing five per cent. interest on the property, rights, and franchises of the company. This issue of bonds is intended to pay for the entire construction of the road, which will cost upward of $5,000,000 with equipment, to pay off all outstanding obligations, including the bonds issued by the old company, and to leave a surplus in the treasury for current expenses. After the adoption of these resolutions the stockholders adjourned *sine die*. The directors met immediately and voted to issue the $6,500,000 in bonds as provided by the stockholders.

ELECTRIC RAILWAY FINANCING IN RHODE ISLAND.

THE entire surface-car system of Providence has been sold by the Union Railroad Company. This includes every cable, electric and horse car line in the city, an exclusive franchise of every street in Providence for twenty-five years, and the right to equip every line with electricity. The reported price paid for the control is $5,000,000, and the consummation of the deal created something akin to a sensation in financial circles. The officers of the company refuse to give the names of the syndicate which has purchased a controlling interest of the stock, but it is declared by persons in authority to be the Metropolitan Traction Company of New York and the Thomson-Houston Electric Company.

A syndicate is also attempting to purchase the franchises of the Pawtucket Valley Electric Railroad, which has the right to operate all through the central and southern parts of the state. A Philadelphia syndicate has also made a big offer for the entire plant of the Inter-State Street Railway Company, which connects Northern Rhode Island and Southern Massachusetts.

A "STRIKE" AT ELECTRIC ROADS.

THE following bill has been introduced in the New York legislature: Section 1. On and after the passage of this act the use of electric wires or contrivances above ground for the operation of street cars in the cities of this State shall be unlawful. 2. Immediately on the passage of this act, it shall be the duty of the Electric Subway Commissions in cities where such bodies exist, and elsewhere of the Commissioner of Public Works to direct the placing underground of all electric wires and contrivances in use in the operation of street cars, so that the work can be completed on or before December 31, 1893.

SOCIETY AND CLUB NOTES.

FRANKLIN ELECTRICAL SOCIETY LECTURES.

A COURSE of lectures under the auspices of the Franklin Electrical Society will be given at the Evening Trade School, 225 and 227 East Ninth street on the five consecutive Saturdays from February 11 to March 18 inclusive, commencing at eight o'clock in the evening. The subjects will be; Feb. 11, Electrical Transmission of Energy, by Newton Harrison; Feb. 18, The Earth in Past Ages, by E. S. Barney; Feb. 25, Chemistry and its Relation to Electricity, by J. A. Moses; March 11, Development of the Electric Arc Lamp, by E. V. Lallier; March 18, Dynamo Electric Machinery, by W. Wallace Ker.

Tickets may be had from Mr. A. A. Hammershlag, the secretary, at room 301, Electrical Exchange Building, 136 Liberty street.

THE MONTREAL ELECTRIC CLUB.

THIS club has been recently organized among the practical electricians of Montreal for the discussion of electrical topics and the mutual advancement of its members in the knowledge of electrical science. Suitable quarters have been secured on Phillips' Square, where meetings will be held every two weeks. The following are the officers of the club: Mr. W. B. Shaw, president; Mr. J. A. Farlinger, vice-president; and Mr. J. Burnett, secretary-treasurer. Mr. H. Woodman read an instructive paper on "Outside Construction" at a meeting held on Feb. 6th. At the previous meeting an interesting paper was read by Mr. James Burnett treating the different methods of connecting the armature and field windings of dynamos and motors.

PERSONAL.

MR. J. POTTER.

Mr. J. Potter, who has been for many years treasurer of the Brush Electric Company and is president of the Short Electric Railway Company, Cleveland, has resigned these offices to take effect at the convenience of the companies. Mr. Potter graduated from Princeton College in 1877. For several years he was master in the Lawrenceville school, during which time he read law. In 1881 he decided to engage in the electrical industries, and made an engagement with the Brush Electric Company to take charge of its business in China and Japan, and was a pioneer of electric lighting in those countries. He resided for a number of years in Yokohama, and made large contracts for Brush apparatus with the Chinese and Japanese governments, and established the first electric lighting stations in the Orient. In 1884 he returned to Cleveland to take the positions of a director and treasurer of the Brush Company. It is understood that Mr. Potter will devote himself entirely to his private business interests. He is one of the promoters of the projected Lake Street and Crosstown railway in Cleveland. He is also interested in a number of electric railway enterprises, to which he will also give attention.

MR. ANGUS S. HIBBARD.

After seven years of most successful work as general superintendent of the American Telegraph and Telephone Company (Long Distance Company) Mr. Angus S. Hibbard has resigned his position in order to assume the general managership of the Chicago Telephone Company. Viewing the work accomplished by Mr. Hibbard, the Chicago Telephone Company is to be congratulated upon securing the services of so able an officer, whose work will no doubt soon become apparent. Mr. Hibbard will be aided in his work by Mr. W. T. C. Baldwin, who has resigned from the electrical staff of the Metropolitan Telegraph and Telephone Company, of New York, and assumed the position of superintendent of the Chicago Telephone Company.

MR. DAVID E. EVANS.

It will be gratifying to the many friends of Mr. David E. Evans, of the firm of D. E. Evans & Co., of Baltimore, to learn that he has been appointed consulting engineer for the Petersburg, Va., municipal electric lighting plant, having been selected for the position from among 165 applicants.

Mr. Evans went to Baltimore in 1880 and built the first electric light station in the world, that is to say, the first station that was designed from the ground up for the purpose of electrical distribution. Mr. Evans' experience in central station as well as in isolated plant work places him among the most prominent and successful electrical engineers in this country.

Mr. B. F. Meek, Jr., for several years the secretary of the Northwest General Electric Company, has been promoted to the vice-presidency of that company. Mr. Meek has been connected with the company since its organization in 1888, surviving all the many changes that have taken place in its ranks since that time.

Mr. W. A. Kreidler, the publisher and principal owner of the *Western Electrician*, was married last week to Miss Netta O. Preston, and after the ceremony at Elgin, Ill., left for an extended wedding trip through Florida.

LITERATURE.

Text-Book of Experimental Engineering. By Rolla C. Carpenter, M. S., C. E. & M. M. M. *New York,* John Wiley & Sons, 1892. 709 pp. 6 by 9¼. Price $6.00.

The testing of machines and materials and prime movers has now become so important a branch of the engineer's work, that a course of work of this nature is deservedly given prominence in our best schools at the present day.

The author has in the present volume gathered a most valuable series of data and methods which are intended as a text-book of experimental engineering to guide the student in his work.

The work before us first brings before the student the methods of reducing experimental data, then the apparatus by which the measurements are made, pointing out their errors and methods of employment. From these the author passes on to the general formula of the strength of materials and the description of various testing machines. In this way he successively treats of the testing for friction and of lubricants, the measurement of liquids and gases, and of the principal prime movers. The steam engine and steam in general are given special prominence, but we note an entire absence of all mention of the dynamo and electric motor. Such an omission might have been condoned 10 years ago, but now it cannot be forgiven. The present importance of these machines, ought, we think, to have secured for them at least some mention in the present work. With this exception the book can be heartily recommended as a text-book and guide in laboratory work. The engravings throughout are clear, and the book is got up in excellent style.

Minutes of the Proceedings of the Engineering Association of New South Wales. Vol. 7. *Sydney, N. S. W.* Published by the Association, 1892.

LETTERS TO THE EDITOR.

THE ACTION OF THE TESLA MOTOR.

I have just seen a work on "Continental Systems of Electric Lighting," by Hedges, and was surprised to find in it a statement to the effect that the Tesla two-phase motor was inferior to the three-phase motor, in the fact that it would not start itself but had to be brought up to synchronism with the generator before it would run as an alternating current motor. This statement, however, is so evidently a mistake that I would not have called attention to it if I had not found on the same page a statement which seems to have received quite general credence, namely, that "the rotating field produced by the two-phase current consists of a pair of rotating poles that fluctuate in intensity, while that produced by the three-phase current, although it fluctuates to some extent, gives a good deal less variation."

I do not know who is responsible for this statement originally, but it is certainly a mistake, as a moment's thought will show. I call attention to it because I have heard it spoken of by so many different persons that it seems to me to have been pretty generally accepted as a fact. It should be remembered that the two currents in a two-phase motor act upon poles that are at right angles to each other, and the case therefore is one of a combination of two vibrations in planes at right angles with each other and differing by a quarter phase. The old experiments of Lissajous, familiar to every student, show that two such vibrations of the same amplitude and represented by the sine curve, when compounded give a perfect circle, and, in the Tesla motor with the alternating currents varying as the curve of sines, the rotating field may be perfectly constant and produce a perfectly constant pull upon the armature throughout the entire revolution. The difficulty is that in studying the action of these two-phase currents it has been assumed that they are currents represented by vibrations in the same plane, and differing by a quarter phase.

Wm. A. Anthony.

Manchester, Conn., Feb. 8, 1893.

COMPOUND GENERATORS WITH VARIABLE SERIES SHUNT.

The question of the utility of the series coil shunt being still under discussion, I would like to say that I have found a variable shunt, a valuable adjunct to a compound wound dynamo. For, when a generator is over-compounded, by an amount which is countered by a variable resistance in shunt to the series coil, one may change the over-compounding at will, more especially to correct the variations in speed. A builder or designer does not know the range of variations, in speed, his machine may encounter after it leaves the factory, and for that reason I think a variable shunt should be placed on every compound-wound dynamo.

I have adjusted the shunt coils on two dynamos so that the hand regulators did not have to be moved for changes from 100 lights to 3,000 lights. This could not have been done without the variable shunt, unless the maker had a chance to practice with this particular speed in this plant, and then made a fixed shunt to fit it.

L. M. Sheldon.

Boston, Mass. Feb., 7, 1893.

WHEN NATURE LETS LOOSE.

The following is a fair example of what the average lay reporter can do when he essays to write up electrical subjects, and of such is the authority of the sensational press for its strictures on the "deadly current."

The article was published in the New York *Evening Sun* of Jan. 21, and credited to the *St. Louis Republic*:—

Horse Power of a Thunderbolt.

Those who are unacquainted with the facts in the case often express surprise when told that not more than one man in 500 who has been struck by lightning survives, and that with the larger animals the ratio is still smaller. In this age

> of investigation, electric and otherwise, the layman can give explanations for natural phenomena that would have staggered the so-called philosophers of olden times. Thus we find that the E. M. F. of lightning has been a subject of discussion for some time past, amateurs and experts alike taking part in the argument.
>
> At Berlin the great Academy of Sciences grappled with the subject, and the spirited discussions over the "dynamic force of the unseen bolt" were only second to the question: "How shall we kill the comma bacilli?" Making contentions from all those wrangles and deductions, I find that the generally accepted opinion is that the E. M. F. of a bolt of lightning is about 3,500,000 volts, the current about 14,000,000 amperes, and the time of the discharge about 1-20,000 part of a second. In such a "bolt" there is an energy equal to 2,450,000,000 watts, or about 3,284,182 h. p.! Is it any wonder that "lightning usually kills?"

This is not only wrong as to data, but is woefully inaccurate in arithmetic; the energy of a current of 14,000,000 amperes at 3,500,000 volts would be 49,000,000,000,000 watts (watts = amperes × volts) instead of 2,450,000,000, and the horse power $\left(\frac{W}{746}\right)$ would be 65,683,646,118 instead of 3,284,182, as stated in the above article.

Then again the resistance of the air appears to be only .25 ohm $\left(R = \frac{E}{C}\right)$; under such circumstances the transmission of power at 10,000 volts over exposed conductors would be a highly impracticable undertaking.

We advise our friend to avoid exposure during thunderstorms, lest Jove smite him and thereby relieve the fool killer of a duty.

New York, Jan. 23, 1893.

* * *

A CASE OF TEMPORARY ABERRATION.

Did the editor or publisher of *The Electrical World* manufacture his little list of first page paragraphs in the issue of Feb. 4, under the stress of an enlarged cranium too tightly incased in his ordinary hat? Hear him think aloud:—

> **Proper Use of Terms.** We often notice, especially in papers written by mechanical, civil and other engineers who are not electricians, that they use electrical terms incorrectly. We refer at present more particular to the loose way in which the terms kilowatt and kilowatt-hour are used. A kilowatt is a unit of power or activity, and includes the element of time. On the other hand a kilowatt-hour is a unit of work or energy, and is as a unit entirely independent of the element of time; it is precisely like the terms foot-pounds, or horse-power-hour, or joule, into which it is directly convertible.

Could a man get mixed up much worse?

Can anybody conceive of how a volt-ampere, or any number of volt-amperes, can "include the element of time?" May not a watt be as truly a watt if expended only for $\frac{1}{1000000}$ of a second as if such a rate of expenditure were kept up for a year?

Can the said editor, during the lucid intervals when his hat fits him, reflect that "a kilowatt-hour" is as a unit entirely independent of time, when time is one of its factors?

Is it really "precisely like the term foot-pounds," which does not include time (but which may mean a very rapid or a very slow expenditure of energy, according as it is coupled with a rate), and *also* precisely like "horse-power-hour" which always indicates work done at a definite rate per second and also for a definite total period?

Let our friend the editor remember that every tyro in electrical study should understand that as long as volts represent difference of potential, and amperes represent simply and only the number of volts expended in each ohm of the resistance, the product of this total potential difference multiplied by this rate of potential expenditure for each ohm (not a rate as referring to time) will give the watts, which are still watts no matter how minute or how vast the period during which this degree of activity continues. Hence a watt or a kilowatt has nothing to do with time, and the *World* should be careful lest its honored editor places himself in the category of those whom he characterizes as "mechanical, civil and other engineers who are not electricians," —who, by the way, sometimes do write papers which electricians do well to study with care.

W. J. Jenks.

New York City, February 9, 1893.

ELECTRICAL TRANSMISSION IN ITALY.

In Italy, where there are numerous small water powers, the Italian Electrical Society is making many applications of electric transmission. From the Gravellone waterfall near Padua, 200 h. p. are carried half a mile; the Alzano waterfall is used to distribute 180 h. p. at one-third of a mile, 40 h. p. at half a mile, and 50 h. p. at three miles. A plant is now under construction to transmit 1,000 H.P. from the Cassagno falls to Intra, a distance of six miles.

LIGHTING UP THE ATLANTIC.

The Compagnie Transatlantique has again brought forward the question of lighting the Atlantic route, from Ireland to Newfoundland. It is proposed to put ten powerful floating lights 200 miles apart, and connect them by electric cables.

MISCELLANEOUS.

THE K-R LAW IN TELEPHONY.[1]

BY W. H. PREECE, F. R. S.

The institution of telephone exchanges has led to a development of systems of switching that might fairly be considered a special study in themselves, and the demand for communication between distant places has necessitated the application of much special attention to the method of constructing lines and of arranging circuits.

It is in this latter field that I have been a diligent worker, and the application of the so-called "*K R*" law has proved of material benefit in connection with the problems of long-distance telephony. It is a law which implies that the number of signals that can be transmitted per second through any circuit depends solely on the capacity (*K*) and the resistance (*R*) of the circuit. It is very much the fashion to deny the accuracy of the *K R* law. This is probably the result of ignorance of its meaning or of its interpretation. Some speak of it as empirical, others scoff at it as imaginary, and some sneer at it as an impossible law; but it is a law that has determined the dimensions and speed of working of all our long submarine cables; it determines the number of arms a circuit can carry on the multiplex system, the speed attainable with the Wheatstone system, and the distance to which it is possible to work quadruplex; it is a law that has enabled us to bring London and Paris within clear telephone speech of each other, and which will probably before the year is out enable Dublin and Belfast to speak to London—a message of peace to Ireland as solid and substantial as any promised political proposal.

The New York and Chicago trunk line is 950 miles long, and it is built with 435 lb. (or No. 8 S. W. G.) copper wire. This wire gives a resistance of 2.06 ohms per mile, which is easily verified; but it is said by Mr. Wetzler[2] to have a capacity of 0.0158 microfarad per mile, which cannot be verified, and which is absurdly high. 0.0158 microfarad was a measurement made by me in England on an old line, but I have frequently pointed out that owing to the use of earth wires the capacity of our English lines is very much greater than that of American lines. Mr. Edison discovered this in 1872 when he came to England to introduce his automatic system. Moreover, I have also pointed out that induction still further diminishes this capacity. The Paris circuit does not exceed 0.005 microfarad per mile. I should estimate the Chicago circuit at 0.004 microfarad per mile, and K R at 7,500, which gives a result that quite accords with the opinions that I have heard expressed by those who have tried the two circuits as to the relative efficiency of the Paris and Chicago lines. My American friends would have done better if they had used thicker wire. I should have specified 600 lbs. per mile; but if it had been in England I should have used 1,000 lbs., for we cannot dispense entirely with cables and underground work as they have done in the States, and the increased capacity introduced must be compensated for by reduced resistance. As a matter of fact, I once proposed 1,200 lbs. wire for a circuit between London and Berlin—a distance of 760 miles, including a cable 55 miles long.

The beneficial effect of induction as a negative capacity is observed when working a circuit telegraphically with automatic high-speed apparatus. Thus, on two copper wires 450 miles long, making 900 miles altogether, the speed on each single wire was 120 words per minute, and on metallic circuit—

Loop *via* different routes..... 120 words per minute.
" on same poles.......... 150 " "

So that the improvement effected by induction was 25 per cent.

There is no difficulty in measuring *R* of a metallic loop. The Wheatstone bridge determines it at once. There is more difficulty in obtaining *K*. It cannot be measured directly. But with a metallic loop of copper, partly overhead and partly underground, there are several modifications required, due to electrostatic and electromagnetic induction, which are at present beyond the reach of formulæ, and render it difficult to determine the capacity except approximately from the telephonic effects themselves. Thus the capacity on the London-Paris circuit proved to be only one-half of that obtained by calculation, and every long circuit will require its own *K* to be determined by comparison with an empirical *K R* scale. Such a scale I have determined by careful experiment on artificial cables.

I have recently devised a new form of cable which will probably quadruple the rate of telegraph working to America; and I may say with all confidence that there is no theoretical reason whatever why we should not converse between London and every capital in Europe, while it is not impossible to speak even across the Atlantic.

---

[1] Abstract from Presidential Inaugural Address delivered before the London Institution of Electrical Engineers, Jan. 26, 1893.

[2] See The Electrical Engineer, Dec. 14, 1892: "The Engineering Details of the New York-Chicago Long Distance Telephone Line," by Joseph Wetzler.

OPENING OF THE LONG DISTANCE TELEPHONE SERVICE BETWEEN BOSTON AND CHICAGO.

THE handsome offices of the American Telephone and Telegraph Company, at 125 Milk street, Boston, were crowded on Tuesday evening, the 7th inst., by about 400 of Boston's most influential citizens to witness the opening ceremony of the long distance service between Boston and Chicago. The room is a large one on the ground floor and was handsomely decorated for the occasion. In the centre of the room was situated one of the usual long distance desks, with transmitter and receiver as shown in our engraving, and immediately adjoining was a table covered with yellow silk, upon which rested about forty ordinary hand telephones or receivers. Overhead attached to the electrolier and covered from view by means of festoons of evergreens, were two other receivers attached to which were bell-shaped horns, for the purpose of emitting the musical strains which came all the way from Chicago. Shortly after four o'clock Governor Russell appeared on the scene, and as if inspired by magic the musical horns began to breathe forth the inspiring strains of "Hail to the Chief." The music was rendered perfectly and could be heard most distinctly all over the room, although transmitted some 1,200 miles. The Governor then took his position at the instrument, with Lieutenant-Governor Wolcott directly behind him, and Adjutant General Dalton on his left hand, easily recognizable as the only gentleman present in uniform. Governor Russell, after being photographed at the desk, called up Chicago and spoke for a few minutes with Mr. Wendell Baker, the special agent for the American Telegraph and Telephone Company in Chicago, stating that he congratulated the company upon the extension of the long distance lines from Chicago to the State of Massachusetts, and that he looked upon the enterprise as a most important commercial event. He regarded the completion of this work as one of many ties that would bind us closer together as a nation. The conversation was distinctly heard in Chicago, and Mr. Baker's replies were most distinctly heard by the Governor and forty of the guests fortunate enough to have secured the spare receivers. After the ceremony, while numbers stayed to talk further with Chicago, others went to the top of the building and inspected the magnificent switchboards of the local telephone company and the Long Distance company, after which all adjourned to a room on the second floor of the building, where a most substantial collation was laid out. It was enjoyed to the accompaniment of music by the Germania Orchestra. The entertainment lasted from four until seven and it was the universal opinion that the Long Distance Company had provided an entertainment unique in character, and most interesting and enjoyable in all its details.

ELECTRO-HYPNOTISM IN CONGRESS.

THERE are some curious bills before Congress. Senator Mitchell has introduced one, "by request," which is to prohibit electro-magnetizing, mesmerizing, or hypnotizing human beings, or affecting one person through another with electricity. The petition accompanying the bill speaks of the systems "which prevail among magnetizers and theosophical sections [*sic!*] of transferring the magnetism of others, thus weakening the understanding and disturbing the concentration of thought by depleting the brain." The gravity of these facts has so impressed the originator of the bill that he proposes neither more nor less than that electro-magnetizers, mesmerizers, hypnotizers, and electric fiends convicted of practising their dangerous arts within the District of Columbia, or the territory or waters within the jurisdiction of the United States, shall be punished with death, while those who, knowing of such practices, fail to give information to the rightful authorities, shall be imprisoned (for life, if deemed advisable) and made to pay a fine of not less than $5,000 besides.

THE TARIFF AND ELECTRIC RAILWAY MATERIAL.

A DISPATCH from Washington of February 7th says: "When the Senate a few days ago referred to the Finance Committee the bill which had been favorably reported by the Commerce Committee permitting the St. Louis & Chicago Electric Railroad Company to import free of duty machinery necessary for the construction of the road, the Republican protectionists in the Senate thought that the bill had been pigeon-holed for the session. However, the Finance Committee this morning disappointed these expectations and resolved to report the bill back to the Senate with the recommendation that it pass, and, of course, this was achieved by the aid of Republican votes in the committee. So the bill enjoys the distinction of being the first and probably the only bill touching the tariff which the Finance Committee has reported or will report to the Senate this Congress."

NEW COMPETITION TELEPHONE COMPANIES.

It is rumored that the old Meucci Telephone Company, of which James R. English, of Elizabeth, N. J., is president, is about, it is alleged, to revive its charter and begin active operations in Elizabeth and other cities of New Jersey.

The Meucci Company once had a regular system in operation in Elizabeth, but had to discontinue business on account of infringing the Bell Company's patents now expiring. Report has it that capitalists of Elizabeth, Newark, Plainfield, and some other cities are about to organize a strong company to build both trunk and local lines to operate throughout the State, and to control the Meucci franchise and the poles and wires of the New Jersey Postal Telegraph Company, which has a system now doing a general telegraph business between New York and Asbury Park and touching at all intermediate cities and towns. It is said that a large factory is now in course of construction at Red Bank for the exclusive manufacture of telephones to be sold outright for general use and that it has already filed orders ahead for several months.

It is also rumored that some of the capitalists in the Standard Oil Company will also be competitors and will engage actively in the business of making telephones.

A new telephone company, with a capital stock of $80,000,000, has applied for incorporation at the office of the Illinois Secretary of State. The name chosen is the Harrison International Telephone Company, and two conspicuous members of the Directory are Major William Warner and Richard C. Kierens. Mr. Warner is the ex-Commander in Chief of the Grand Army of the Republic, and Mr. Kierens is a well-known railway magnate and Missouri's member of the Republican National Committee.

The other directors are Dr. E. M. Harrison, of Forth Smith, the inventor of the telephone; L. E. Ingalls, of Chicago; George R. Peck, of Topeka, Kan.; Charles M. Feree, Albert L. Stone, John T. Blake, Howard M. Holden and Webster E. Davis, of Kansas City, and D. J. Young.

Charles M. Feree is president of the company, Howard M. Holden vice-president, Albert L. Stone secretary, and a prominent Chicago man, name withheld, is treasurer. A number of the directors are in Chicago and have been quietly holding meetings at the Grand Pacific Hotel.

The incorporators say that they can give service for one-half the rates now charged. President Feree said: "We will construct a circuit between New York, Boston, Buffalo, Cleveland, Detroit, St. Louis, Louisville, Cincinnati, Pittsburgh, Philadelphia, Washington, Baltimore, and from there back to New York.

"This circuit will cost $10,000,000, but we expect it to yield handsome dividends. One of the most important features of our new system is that we expect to do away entirely with the telephone girl. We do this by a system of automatic switchboards. In conjunction with the telephone we will have a new system of telegraphy by which messages are written out and an exact facsimile is transmitted to the receiver."

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 31, 1893.

Accumulators:—

Secondary Battery Electrode, H. G. Osburn, Chicago, Ill., 490,758. Filed No. 21, 1891.

A plate having a multiplicity of bars deflected in opposite directions and forming receptacles for active material, and a re-inforcing conductor extending through the receptacles.

Alarms and Signals:—

Electric Block Signal System, J. La Burt, New York, 490,663. Filed Dec. 14, 1891.

A automatic electric block system for steam railways.

Automatic Alarm Device, G. W. Schilling and J. G. Haslam, Philadelphia, Pa., 490,684. Filed June 18, 1892.

An electric alarm for pipes supplying automatic sprinklers.

Electrical Time Indicating Apparatus, E. Weston, Newark, N. J., 490,698. Filed June 16, 1891.

Electric Burglar Alarm, W. H. Carr, Bath, Me., 490,870. Filed Sept. 22, 1892.

Electric Signaling System, A. J. Wilson and W. W. Salmon, Chicago, Port Chester, N. Y., 490,761. Filed Sept. 14, 1892.

An automatic block system for steam railways.

Conductors, Conduits and Insulators:—

Insulating Compound, M. H. Devey, Chester, Pa, 490,641. Filed Jan. 30, 1892.

A composition of powered slag, glass, boiled linseed oil, driers, shellac and paraffine.

Connector for Electrical Conductors, G. L. Russell, Middletown, Conn., 490,755. Filed Aug. 12, 1892.

Consist of a plate having a sharp edge, a clamping piece having a hook acting with the edge, and means for adjustably fastening the two parts together.

Dynamos and Motors:—

Dynamo Electric Machine or Electric Motor, R. Lundell, Brooklyn, N. Y., 490,810. Filed April 22, 1892.

Employs two hollow disc shaped field magnet coils each wholly enclosing a single field magnet coil, the latter being placed on opposite sides of the armature and in a plane parallel therewith.

Dynamo Electric Machine, R. Lundell, Brooklyn, N. Y., 490,809. Filed April 22, 1892.

Employs a disc armature and a single field magnet coil lying in a plane on one side of the armature and parallel with it, in combination with radially disposed multipolar pole pieces between which the armature rotates.

Heating:—

Electric Warming Bottle, T. Ahearn, Ottawa, Can., 490,891. Filed Sept. 8, 1892.

Lamps and Appurtenances:—

Manufacture of Carbon Filaments for Electric Lamps, T. A. Edison, Llewellyn Park, N. J., 490,954. Filed Nov. 6, 1886.

Consists in first forming filaments of carbonizable material, partially carbonizing them and afterward soaking them in a solution of a carbonizing substance and finally completely carbonizing them all.

Combined Gas and Electric Light Fixture, F. X. Gartland, Philadelphia, Pa., 490,908. Filed Jan. 23, 1892.

Electric Arc Lamp, J. Sugden & W. J. L. Sandy, London, England, 490,998. Filed July 13, 1892.

Relates to automatic mechanism for feeding the carbons of arc lamps.

Measurement:—

Recording Ammeter, E. Weston, Newark, N. J., 490,699. Filed March 18, 1892.

A recording ammeter having an arm actuated by a coil in the field of force and carrying a tracing device; and a moving record surface upon which the latter makes its record.

Electrical Measuring Instrument, E. Weston, Newark, N. J., 490,700. Filed March 29, 1892.

Employs a metal filament, an index controlled by the elongation and contraction of the former, and a support for the filament made of an alloy whose coefficient of expansion is the same as that of the filament.

Telethermometer, H. B. Payne, Chicago, Ill., 490,883. Filed Sept. 22, 1892.

Telethermometer, H. B. Payne, Chicago, Ill., 490,883. Filed May 20, 1892

Electrical Measuring Instrument, E. Weston, Newark, N. J., 490,760. Filed Oct. 3, 1892.

Employs two stationary coils side by side, a shaft extending diametrically through both coils, two other coils wound in opposite directions supported upon the shaft and disposed between the fixed coils, and a spring connected with the shaft and also with an abutment for the purpose of opposing the shaft's vibration.

Miscellaneous:—

Apparatus for Electrically Treating The Eyes, W. A. Price, Iowa Falls, Iowa, 490,678. Filed Sept. 24, 1892.

Apparatus for Electrically Treating The Ear, W. A. Price, Iowa Falls, Iowa, 470,679. Filed Sept. 29, 1892

Electrical Pressure Indicator for Steam Gauges, E. G. Smith, San Jose, Cal., 490,725. Filed July 6, 1892.

Electric Time System, W. F. Gardner, Washington, D. C., 490,744. Filed Sept. 4, 1891.

Art of Generating Electricity, T. A. Edison, Menlo Park, N. J. 490,953. Filed Nov. 1, 1883.

Consists of subjecting carbon to heat in an exhausting chamber and in the presence of an agent which combines with it.

Electric Belt, J. W. Cummings, Gold Hill, Nev., 490,948. Filed July 27, 1892.

Railways and Appliances:—

Electric Railway, E. W. Mitchell, Covington, Ky., 490,975. Filed June 23, 1892.

Employs a feed wire within an insulating covering having openings at intervals, a sectional service conductor extending along the line of the feed wire and having contacts which make connection with the latter when the car is passing.

Trolley Wheel, J. J. Goetz, Covington, and J. A. Smith, Dayton, Ky., 490,014. Filed May 20, 1892.

Switches and Cut-Outs:—

Electric Switch, J. S. Gibbs, Hartford, Conn., 490,746. Filed Nov. 1, 1892.

Consists of a base supporting double revolving poles and a key connected with both so that they act in unison.

Switch and Safety Fuse, E. P. Morris, Boston, Mass., 490,917. Filed Feb. 11, 1892.

Consists of a box containing the switch having a spindle projecting through the cover and having contact plates to which the fuse is secured, contacts in the box connected to the line and to the switch and engaging the contacts on the cover.

Electric Circuit Breaker, E. M. Bentley, Boston, Mass., 490,762. Filed Nov. 19, 1892.

Employs a travelling arm as one member, with a compressor moving with the arm and automatically delivering air across the arcing space at the instant of the breaking of the circuit.

SUGGESTIONS FROM THE COMMISSIONER OF PATENTS.

The Commissioner of Patents, in his annual report to Congress, shows that there has been a great improvement in the Patent Office under the workings of the classified service rules, and says that the appointment of commissioner and assistant commissioner should cease to be political, their salaries should be increased, and they should hold their offices on the tenure of good behavior.

Regarding the Patent Office exhibit at the World's Columbian Exposition, the report says that it will comprise upward of 2,500 models, nearly all of them working machines arranged in chronological order beginning with the first crude implement and ending with the latest improvements.

The report recommends legislation concerning international patent matters, says that our patent law is exceptionally liberal toward foreigners, and urges that legislation be enacted that will place American inventors on the same footing in foreign countries.

A number of amendments to the patent and trade-mark laws are embodied in the report. They are to the effect that no improvement shall be patentable which has been for more than two years before application for patent thereon disclosed in any patent or printed publication issued in this country; that a patent shall not expire with the expiration of a prior foreign patent for the same invention; that an applicant be compelled to take action upon his application at least once every six months; that a patent shall in no case live for more than twenty years from the date of first application therefor; that aliens be put upon the same footing as citizens as to the filing of caveats; that interference contests be abolished in the Patent Office and be relegated to the courts.

LEGAL NOTES.

INCANDESCENT LAMP LITIGATION.

EDISON ELECTRIC LIGHT COMPANY ET AL. (GENERAL ELECTRIC COMPANY) VS. WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY.

DOES THE NEW WESTINGHOUSE LAMP INFRINGE THE EDISON PATENT?

AT Pittsburgh, on Thursday, February 9, argument was heard in the United States Circuit Court for the Western District of Pennsylvania, by Judges Buffington and Acheson, upon a motion by the complainants to dismiss the motion of the Westinghouse Company for an order of the Court upon the complainants to show cause why the Edison Company should not be restrained from interfering with the defendants in the manufacture and sale of the new Westinghouse lamp. As is now well known, the Westinghouse Company claim that their new lamp does not infringe the second claim of the Edison patent, and their motion above referred to was for the purpose of securing a judicial opinion in that regard.

The motion for an order to show cause, made in behalf of the Westinghouse Company, was fortified by affidavits of George Westinghouse, Jr.; W. K. Carlisle; Frank S. Smith; O. B. Shallenberger and Daniel C. Ripley, tending to establish the proposition that the new Westinghouse lamp is not covered by the claim of the Edison patent; describing to a considerable extent the construction and process of manufacture of the new stopper lamps; and alleging that nothing was involved in the structure of the new Westinghouse lamp beyond an application of the instructions or information imparted by Sawyer and Man, and by them made a part of the art, in their patents prior to the date of Mr. Edison's invention in October, 1879, along with the use of good mechanical skill in following such instructions. It was also shown by defendants that they had in January submitted specimens of their new lamp to the counsel of the General Electric Company for examination, at the same time requesting their opinion upon the question of infringement; they also made affidavit that the new lamps were, about the middle of January, put upon the market and had since been sold and shipped in considerable quantities, in the regular course of the defendant company's business, under advice of their counsel.

The complainants submitted affidavits by J. H. Herrick, S. D. Greene and F. R. Upton. Mr. Herrick in his affidavit includes as exhibits, circulars of the Westinghouse Company, issued at various times since October 6th to users of incandescent lamps, alleging that their new lamps not only did not infringe the Edison patent, but were fully covered by patents of their own, and that they would presently be prepared to supply the market in large quantities and at prices very much below those generally prevailing. Mr. Herrick's affidavit alleged further that by means of misrepresentations as to its ability to supply the trade with lamps at greatly reduced prices, and by other inducements, the Westinghouse Company had endeavored to prevent the complainants from securing the benefits of the successful termination of the Edison patent litigation.

Mr. Greene's affidavit set forth his disbelief that the new Westinghouse lamp had gone into commercial use anywhere. He had not heard of a single plant which had received such lamps.

Mr. Upton testified that samples of the Westinghouse lamp had been turned over to him for testing and the determination of the process of construction and mode of operation, but the number of lamps submitted had not been sufficient to enable him to make systematic tests.

Mr. Grosvenor P. Lowrey made the argument for the complainant and Mr. George H. Christy for the defendant.

Mr. Lowrey said, in support of complainant's motion to dismiss, that the question of infringement was too vast to be taken up and disposed of upon such a motion. It should be brought up by a supplemental bill or an original suit; he did not think it would be a proper course to serve the defendant with an attachment for contempt of court for use of the stopper lamp, as the question of infringement was so difficult a one to determine. The complainants ought to have more time to examine the construction and operation of the new Westinghouse lamp, and required many more samples of it for examination than they had yet been supplied with; and they were willing to pay for them.

Mr. Christie urged a prompt decision upon the complainant's motion to dismiss so that the main question of infringement could be reached as early as possible. In respect to the alleged novelty or unusualness of the present form of proceeding, he showed that for a long time it had been the practice in the Pennsylvania Circuit to allow the defendant under injunction to ask the court for a modification or a construction of the injunction order in precisely the manner now asked in this case.

The argument lasted through Thursday and Friday, and at its close the court took the papers, reserving decision.

The Westinghouse Company has also applied to the court for an order to restrain the complainant from bringing suit elsewhere, that is, against the Westinghouse Company's customers, pending the argument upon the order to show cause. That argument is, of course, deferred until the court decides upon the complainant's motion to dismiss.

GOVERNMENT ATTACK ON THE BERLINER PATENT.

A SPECIAL despatch from Washington, of February 9, says:—"Attorney-General Miller to-day filed a complaint in the United States Circuit Court for the District of Massachusetts, at Boston, against the American Bell Telephone Company and Emile Berliner. It is in thirteen paragraphs, and asks for an annulling of patent No. 463,569 for a combined Telegraph and Telephone applied for by Berliner on June 4, 1877, and issued November 17, 1891, to the American Bell Telephone Company as Berliner's assignee.

"The grounds upon which the application for annulling the patent is made are that the claims set up in the Berliner patent, granted in 1891, are covered by previous patents issued to the Bell Company, beginning with the original Bell patent, No. 174,465; that the possession of said patent No. 463,569, if valid, will continue to the Bell Company without substantial diminution during the full term thereof the same close monopoly of the art of telephony in the United States, which it has enjoyed under patent 174,465; and that it is against the spirit and intent of the patent laws, and against justice and equity, that the monopoly of one and the same invention shall be prolonged in one and the same person by the grant, first of a patent or patents, for the invention in practical and applied form, and afterward of a patent covering nakedly and broadly the fundamental principle of the same invention."

The complaint was presented by Mr. Robert S. Taylor, as special counsel. Mr. Taylor is a well-known patent lawyer of Fort Wayne, Ind.

TELEGRAPH LITIGATION—OPINION IN A LOTTERY CASE.

IN the case of the United Lines Telegraph Company and Edward S. Stokes, appellants, vs. the Boston Safe Deposit and Trust Company, on appeal from the United States Circuit Court for the Southern District of New York, the Supreme Court, in an opinion rendered by Justice Blatchford, has affirmed the decree of the lower court in favor of the Rapid Company. The dispute concerned the ownership of a line of telegraph between Cleveland and Chicago, one party claiming under a Rapid mortgage of $3,000,000, and the other under a mortgage from the Bankers' and Merchants' Company amounting to $10,000,000. Justices Brewer and Field dissented.

OBITUARY.

DR. NORVIN GREEN.

THE death is announced at Louisville, Ky., of Dr. Norvin Green, who has been president of the Western Union Telegraph Company since 1878, when he succeeded William Orton. The history of telegraphic combination, rather than of creation, is embodied in Dr. Green's career. He was born in 1818 at New Albany, Ind., and in 1840 graduated from the University of Louisville. He practiced his profession of medicine in Louisville for several years, but drifted into politics, and then early in the fifties became interested in the early Morse and People's Telegraph lines between Louisville and New Orleans. He made the telegraph a special study, and followed its fortunes so closely that when in 1866, the American, United States and Western Union lines were consolidated he became vice-president of the company, and held the office until 1873. Three years later he came back to the telegraph, and was again the vice-president of the new and larger Western Union. The sudden death of Mr. Orton in 1878, gave Dr. Green the commanding position he had so long been in training for, and which he was so well fitted to occupy. That he did his work well, the steady, magnificent, solid growth of the company shows. He liked his duties and held on until advancing age and sickness drove him back, for the last time, to his old Kentucky home.

Dr. Green was a giant in physique, of large social instincts, of judicial mind and executive turn, fond of a joke and good story, a great smoker and a great club man. He leaves a wife, four sons and two daughters. One of the sons married a daughter of Abram S. Hewitt. It is estimated that Dr. Green leaves a fortune of $2,000,000, chiefly in Western Union stocks. It deserves mention that Dr. Green was one of the founders of the American Institute of Electrical Engineers, and its first president, serving two consecutive terms. He took great interest in the growth of the Institute, and attended the council meetings with exemplary regularity.

TRANSPORTATION TO THE ST. LOUIS CONVENTION.

An excursion rate of a fare and a third has been granted to St. Louis and return for delegates attending the Convention of this Association by all the Passenger Associations except the Western; negotiations are now pending with them and in all probability they also will grant this concession. Arrangements have been perfected for a special train to carry the Eastern delegation, which will be vestibuled, electrically lighted, and composed of dining, buffet, observation and sleeping cars, and will leave New York, *via* Pennsylvania Railroad, from stations foot of Cortlandt and Desbrosses streets, Sunday, February 26, at 12 o'clock noon; Philadelphia, 2.25 p. m.; Harrisburg, 4.25 p. m. Pittsburg, 10.40 p. m. (central time); Columbus, 4.35 a. m.; Indianapolis, 10.30 a. m.; arriving at St. Louis at 5.30 p. m., Monday, February 27.

The rate for berths is $6.00 each; drawing-rooms, $22.00 each.

For the convenience of passengers taking this train from New York, arrangements have been made that if they will remit to the undernamed the amount of railroad fare ($24.25) with the sleeping-car fare ($6.00) a receipt will be mailed them that will be honored by the railroad company for checking baggage, ferry passage, and passage through the gate at Jersey City, and exchangeable on the train for regular railroad ticket and certificate.

The Boston Passenger Committee have declined to sell tickets at a reduced rate from Boston *via* New York; therefore the Eastern delegation who desire to take the Electrical Special will be compelled to come to New York, purchase tickets and secure certificates from New York to St. Louis and return. It is quite important that all the names of delegates who will be passengers on the Electrical Special shall be known as soon as possible.

The following named gentlemen have charge of transportation matters for their various territories: Morris W. Mead, Pittsburg, Pa.; Fred. W. Royce, Washington, D. C.; H. A. Cleverly, Philadelphia, Pa.; A. C. Shaw, Boston, Mass.; John Carroll, Montreal, Can.; M. J. Hart, New Orleans, La.; John W. Flintham, Denver, Col.; J. Scribner, 173 Adams street, Chicago; Louis Nahm, St. Louis, Mo.

To secure the benefit of the reduced fare returning, it will be necessary for those who do not go by the Electrical Special to be sure and state to the ticket agent from whom they purchase the going ticket that they purpose attending the meeting of the Association at St. Louis, and procure from him a certificate which will entitle them, when properly viséd and countersigned, to return for one-third the regular fare. No reduction can be obtained without this certificate. Immediately upon arriving in St. Louis these certificates should be left in the Secretary's office, addressed to C. O. Baker, Master of Transportation, who will see that they receive proper attention and are returned to the owners.

TELEPHONE MEETING OF THE NEW YORK ELECTRICAL SOCIETY.

At the meeting of this Society, held at Columbia College on February 8, a large gathering of members and visitors assembled to listen to a lecture on "The Telephone, and how we talk from New York to Chicago."

The lecture was divided into two parts, the first of which comprised what may be termed the philosophy of the telephone. This part was given by Mr. J. J. Carty, chief electrician of the Metropolitan Telephone and Telegraph Co. of New York. Mr. Carty began by explaining the nature of sound and the mechanism of speech, showing the functions of the various parts of the throat, mouth and teeth in the utterance of intelligible sounds. He then showed how sound may be propagated directly through the air, or by means of liquid or solid conductors, and finally by the aid of electricity. In leading up to the Bell receiver Mr. Carty explained the mechanical and electrical principles involved in its operation, and also gave a lucid explanation of the battery transmitter and the variable carbon contact.

Mr. Carty was followed by Mr. F. A. Pickernell, chief engineer and electrician of the Long Distance Telephone Company, who described the methods of construction adopted in the design and erection of the long distance line between New York and Chicago. Both Mr. Carty's and Mr. Pickernell's remarks were illustrated by stereopticon views.

Through the courtesy of the Long Distance Company the Chicago line had been run into the lecture hall with forty receivers in circuit. At the conclusion of Mr. Pickernell's remarks an exhibition was given, including the transmission of speech, cornet and banjo from Chicago. Notwithstanding that forty receivers were in circuit, the volume of sound was such as to leave nothing to be desired. The members and visitors present, with one accord, expressed their delight with the evening's entertainment.

The New York Electrical Society is rapidly increasing in membership, and its work is being more and more appreciated.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE ANSONIA ELECTRIC COMPANY.

Changing the name of an old established business would seem to the man outside very like swapping horses in mid stream, but to those who are acquainted with the facts and know to some extent the causes that have led up to this step it will not seem so strange to know hereafter The Electrical Supply Company by a new name. We think there is hardly a man or a boy in the country from the manager or president of the biggest central station or electrical railway, to the ambitious youngster who has been striving to make the wheels go round with a few inches of fine wire and some scraps of iron, but who has heard of or known more or less intimately The Electrical Supply Company. of Ansonia, Conn., and Chicago. Hereafter the organization that has established and conducted an immense business under that name will be known as The Ansonia Electric Company. Some of the reasons for this change of name may be briefly given. While this company was the first to assume the name incorporating the words "Electrical Supply" and while by all rules of precedence it considers itself entitled to the undivided use of those words as applied to a company name, it seems that the very nature of the business and the expensive methods that have been employed to make the name known have served also to establish in the minds of the general public an understanding that it is a descriptive name applying to a large class of similar enterprises rather than to one special, distinctive organization, so that many times in referring to the source of certain supplies it would be asked, *Which* "electrical supply" company? During the past few years many concerns have been started all over the country calling themselves this or that "Electrical Supply" Company. While many of these, no doubt, had no thought of appropriating a proprietary name there have been others that have, it is feared, sought and intended to profit by the similarity of titles. This has been of considerable annoyance to the originators of the name.

The managers of The Electrical Supply Company finally determined that it would be best perhaps to change the name. Nothing else but *a change of name* was contemplated and no other changes whatever have been made either in the organziation or the personnel of the company. No consolidations of other concerns and no new relations have been contemplated or established. Under the wise management of its two divisions, the factories in Ansonia, and the salesrooms and warehouses in Chicago, the business has grown to very large proportions. Extensive improvements and additions to the factories in Ansonia have been planned and partly consummated, but it was thought to be a provident and wise thing to assume a name about which there could be no possible doubt or dispute as to its rightful ownership. There is no name in the United States more familiar to the business or electrical field than that of Ansonia. It is known quite as well as New York, Boston, Detroit, Minneapolis, Omaha, Kansas City, New Orleans or Chicago, although perhaps it is not so commonly talked of as Chicago to-day. In the minds of pioneer electric men Ansonia will ever hold a warm place. Among the men who are now prominent in the development of the electric science many have made pilgrimages to Ansonia in the quest of information or to confer with the man to whom can be traced the first practical ideas of the commercial advantages of electric lighting. They who are reading the articles in The Electrical Engineer by Mr. W. J. Hammer, on the work of William Wallace, will have seen how important his work was. It was in Ansonia that the first dynamo was built in this country. It was in Ansonia that the first electric light was used commercially. It was there that Mr. Edison first saw it and there he got the machine to conduct his first experiments. It was an Ansonia built machine that was exhibited at the Philadelphia centennial and furnished the only electric lights shown at that great exposition. It was this same machine that Charles Brush spent weeks examining at the exposition and from which he derived many of his most valuable ideas. In Ansonia the first electric light carbons were made by Mr. Wallace, and he there originated the idea of copper plating them. Hence Ansonia is and must always be in the minds of the older electric people associated with the early days and rise and advancement of a new and great industry.

The name The Ansonia Electric Company is one which very properly belongs to and fits a company that had its start in Ansonia and was established under the guidance of the man and his sons who were so thoroughly and clearly pioneers in the business. Under its new name and its old management, the Ansonia Electric Company has our warmest wishes for its continued success.

The F. P. Little Electrical Construction and Supply Company is the present style of the firm of F. P. Little & Co. The company propose to continue the engineering business of the old firm but on a much larger scale. Mr. Little will continue to be the manager of the company.

CARPENTER ELECTRIC COOKING UTENSILS.

THE CARPENTER ELECTRIC HEATING MANUFACTURING COMPANY of St. Paul, Minn., are introducing a constantly increasing number and variety of cooking utensils provided with their well-known heaters, and so constructed that the most ignorant "Biddy" is in no danger of accidental short-circuits or similar disasters.

The accompanying illustrations represent three of the most important of the new apparatus. The broiler, Fig. 1, is made in two sizes, the small size consuming about seven amperes on 110 volts, and the large one about 12 amperes on 110 volts, and from a cold iron, after turning on the switch, will become sufficiently heated in from three to four minutes so that broiling can be completed on them in less than five minutes. They are constructed with a little slant, so that they may drain to one point at the middle of the lower end.

The baking oven, Fig. 2, is 18 inches long, 14 inches high and 12 inches deep, made of well-seasoned white pine, lined with asbestos felt, and bright tin. There are two sheet-iron shelves in each oven, and also two resistance plates on the bottom and one on the top, connected with a switch on the outside of the oven, so that two temperatures may be obtained. These ovens have a small glass window in each door, so that the baking can be watched. Each resistance plate consumes about five amperes on 110 volts, and it has been found that it only requires from 12 to 15 minutes, at a maximum temperature, to heat the oven to 250° Fahrenheit. The current can then be turned off and the baking continued.

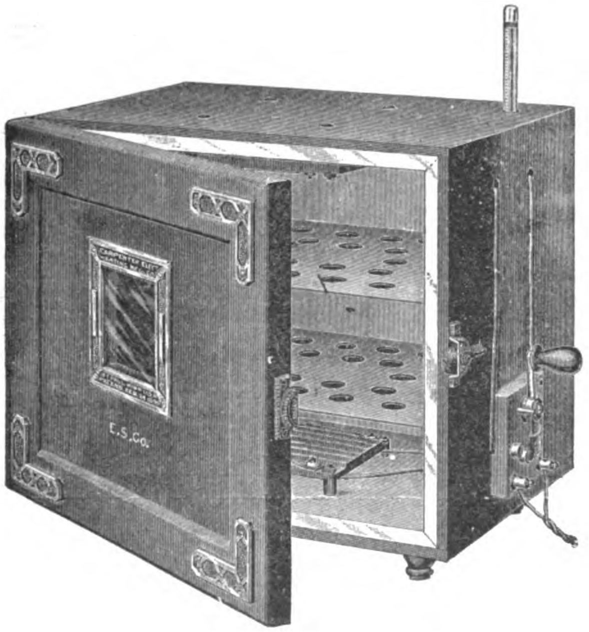

FIG. 2.—CARPENTER ELECTRIC BAKING OVEN.

Fig. 3 shows the chafing dish which requires no special description, but must be very highly appreciated by anyone who has been cheated of a Welsh rarebit in the early morning hours all because there was no alcohol in the house.

The company make also glue pots, curling tongs heaters, sealing wax heaters, flat irons, etc., besides their radiators and car heaters that have already become so widely known, and publish circulars fully explaining their use. The implements are made of excellent material, and in a thoroughly workmanlike manner.

DE RYCKE SEPARATORS.

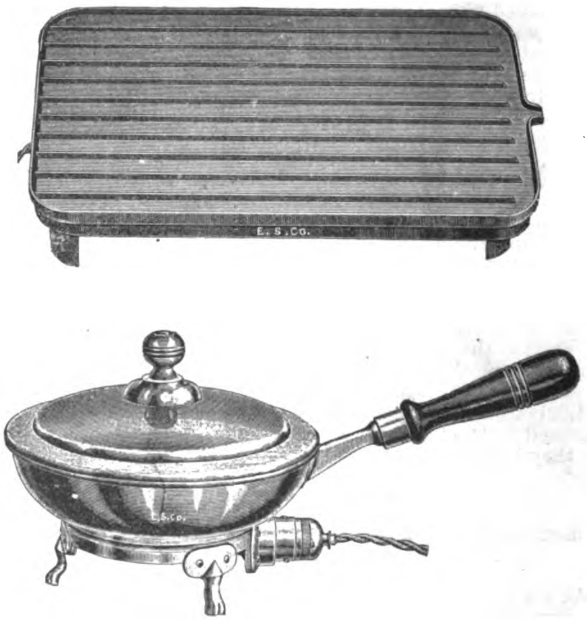
JOSEPH DE RYCKE, 145 Broadway, New York, manufacturer of the De Rycke centrifugal separators and grease extractors, reports that business is very good. Among his recent sales are the following: 44 to Risdon Iron Works, San Francisco agents; 27 to the Crane Company, Chicago agent; four to Willis H. Post, Fort Worth, Texas agent; six to Juan C. Escalar, Cuba agent; four to Bath, Me. Iron Works, for a United States gunboat; one order for 12, a second order for two, a third order for 22, and a fourth order for four, making a total of 40 separators and grease extractors, ranging from three to 12 inches in diameter, to the Milwaukee Street Railway; one order for 12 and a second order for two, ranging four to 18 inches in diameter, to the Cincinnati Edison Electric Company; a twentieth order to Copeland & Bacon, Mining Engineers, 85 Liberty street, New York; six to the Boston Electric Light Company; one to the Newport Electric Light Company; one to the Edge Moor Iron Company; a third order to W. & A. Fletcher Company; a third order to the New Haven Heating Company; one to Chas. S. Salomon; one to George I. Rockwood; two to Fitchburg Steam Engine Company; two to Levi P. Morton; two to the Waco Electric Light Company; one to Liverpool, London and Globe Insurance Company; one each to steamers, "City of Taunton," "John D. Schoonmaker" and "Harry;" a third order to Sulphur Mines Company; one each to the New York & Rosendale Cement Company and the Peabody Electric Light Departement.

THE ELECTRICAL AND MECHANICAL ENGINEERING AND TRADING CO.

THE incorporation last week at Albany is announced of the Electrical and Mechanical Engineering and Trading Company of New York City; to act as consulting, contracting and constructing engineers, for electrical and mechanical construction and to deal in apparatus, materials, etc. Capital $150,000. Directors—J. H. Vail, George F. Sandt, Westfield, N. J.; U. T. Fackenthal, Brooklyn; J. H. Miller, Mount Vernon, and H. Wray Weller, Jamaica.

MASON REGULATOR CO.

A very pretty souvenir and clever advertisement has just been issued by the Mason Regulator Company, of Boston, manufacturers of steam Regulating devices. It consists of a folder representing a U. S. mail bag, with padlocks, rivets and all the rest of it, so correctly reproduced and colored that one seems to be looking at the real thing from a distance and instinctively wonders what there is in it for him.



FIGS. 1 AND 3.—CARPENTER ELECTRIC BROILER AND CHAFING DISH.

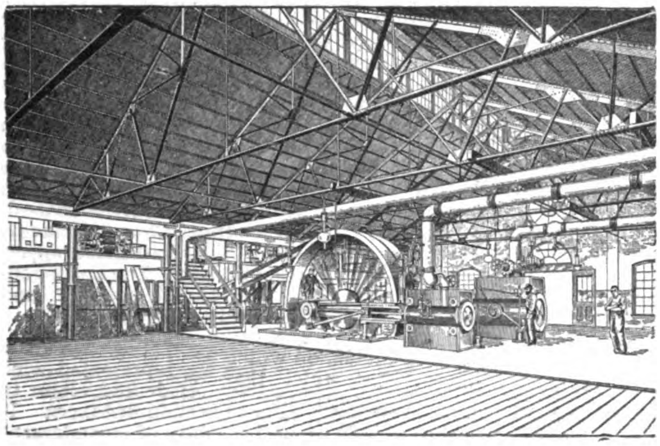
"HE MISSED IT BADLY."

IN beginning his subscription again, a reader in Pennsylvania says: "I felt as though my best friend was dead when your paper ceased coming."

THE AUBURN ELECTRIC MOTOR COMPANY, are having hard work to keep up with their orders in their present limited quarters. The building recently purchased by them for a factory will be ready for their occupancy in about a mouth, which will be fitted up with new and modern machinery. For temporary use they will use a large electric motor of their own make, to run the shop, until frost gets out of the ground so they can set the boilers and engine A 50 h. p. engine will be put in. The company has recently built a plating dynamo for T. L. Caltaud, Lewiston, and are at work on a 4 h. p. 600 volt motor for Bowie Bros.' shoe factory; also a 25-light dynamo for agent Geo. W. Bean of the Androscoggin Mills, to light his residence, a water motor in his cellar furnishing him with the necessary power. A 20-light dynamo has just been completed for lighting J. B. Ham & Company's grist mill, Lewiston, which will be replaced later by one of larger capacity. The company has a number of other orders on hand, and almost every day adds to the list.

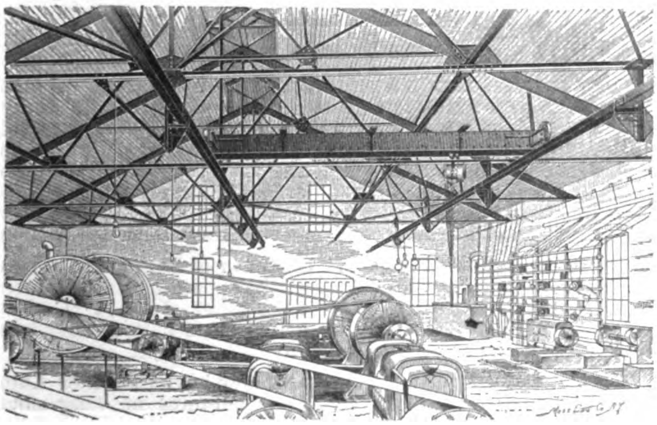
TWO NEW ELECTRIC LIGHT STATIONS WITH IRON ROOFS.

One of the finest electrical plants in the United States is that built by the Pawtucket Gas Company at Pawtucket, R I. The above illustration is taken from a photograph in the engine-room, and shows but a small part of the entire plant. This view is taken in the engine-room more particularly for the purpose of showing the roof which was designed and built by the Berlin Iron Bridge Company, of East Berlin, Conn. The peculiarity in the construction of the roof is that it is covered with their patent anti-condensation corrugated iron. In a place of this kind it is absolutely necessary that not a particle of water should drip from the roof trusses, and the Berlin patent was adopted in order to prevent condensation on the underside of the roof. It has worked perfectly and after being in use during two winters, the present winter being very severe in the vicinity of Pawtucket, R. I., it has shown no signs whatever of any condensation on the underside. The same kind of roof was used on the new station for the Narragansett Electric Light Company, at Providence, R. I., with equally good results, and we understand that the Berlin Company have adopted it universally for electric light stations and other places where drip from the corrugated iron is injurious. If this problem has been solved in such a simple and economical manner, the Berlin Company are to be congratulated. This has been a great trouble with iron roofs in the past, as readers of The Electrical Engineer will remember.



Engine Room of the Pawtucket Gas Company.

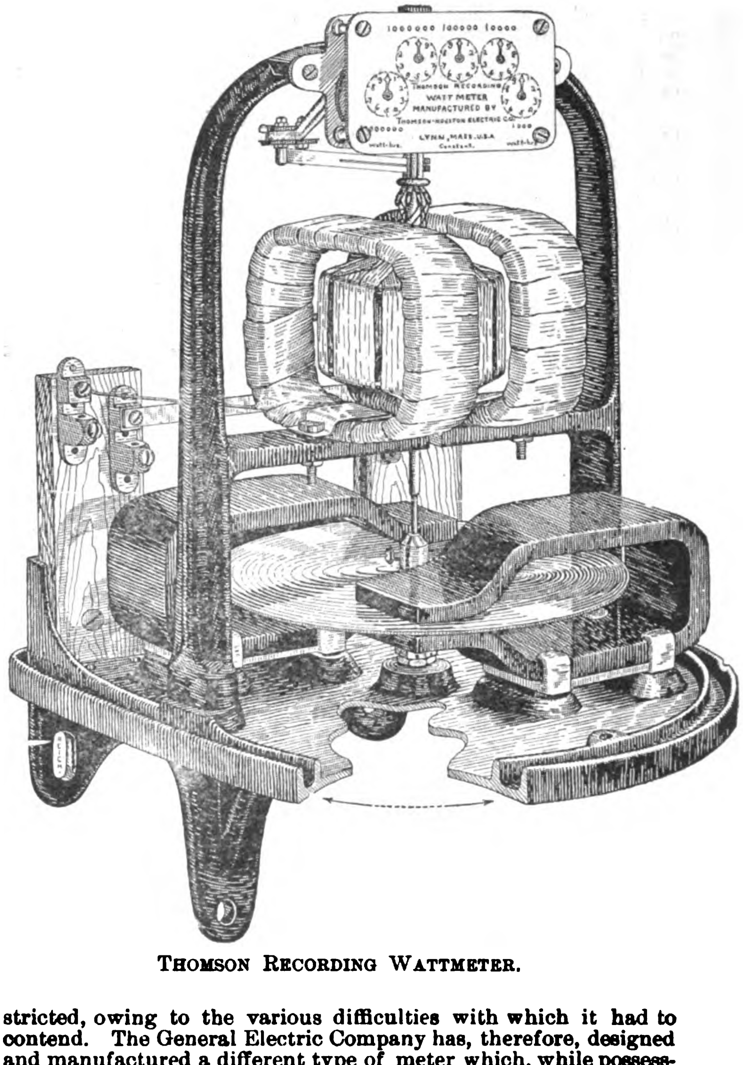
The other illustration is taken direct from a photograph and shows a unique roof construction which we are glad to call to the attention of our readers. It is an iron roof designed and built by the Berlin Iron Bridge Company, of East Berlin, Conn., for a dynamo-room for the Norwalk and South Norwalk Electric Light Company, of Norwalk, Conn. The roof itself is of the well-known Berlin pattern. The building is 60 feet in width and 70 feet in length. It was desired to have a power crane for moving the dynamos in and out of position, but owing to the extreme width of the building (60 feet) a traveling crane was too expensive, especially in view of the fact that it was only desired to control a limited portion of the floor space. To meet this condition the Berlin Company designed the roof trusses in such a way that the traveling crane girders could be secured to the roof trusses at two points, allowing a crane of about 16 feet span to be used with a travel the full length of the building. This crane controls a floor space of 16 feet of the width of the building and the full length, which was all that was desired, and brought the expense for power to move the dynamos in and out to a very economical point. The traveler has a motion on the crane girder lengthwise the full length of the building, and sidewise the motion is secured by a trolley on the crane to which an ordinary chain hoist is attached. The capacity of the traveling crane is 4,000 pounds, which is amply sufficient for all ordinary purposes.



Dynamo Room, Norwalk & South Norwalk, Conn., Electric Light Co.

MOISTURE, GAS AND DUST PROOF THOMSON RECORDING WATTMETER.

The use of the ordinary type of the Thomson recording wattmeter, under abnormal climatic or other conditions, has been restricted, owing to the various difficulties with which it had to contend. The General Electric Company has, therefore, designed and manufactured a different type of meter which, while possessing all the advantages of the well-known meter as used all around us, has special features which enable it successfully to meet the altered conditions.



Thomson Recording Wattmeter.

It is especially designed for service in hot climates where atmospheric influences are corroding, and mephitic gases, damp vapors and minute insects prove detrimental to the ordinary type of recording meter. A glance at the cut will show wherein it differs from the ordinary type. It is a skeleton meter. On the upper side of the lower plate is a groove running completely around it, and in this the cover sets. The groove is filled, after the cover is in place, with heavy oil, gum or cement, preferably a heavy oil. The hole in the base through which the sealing plug of the meter passes is hermetically sealed by means of a soft rubber washer under the wing-nut, while the leading-in and leading-out holes are closed around the wires by a rubber diaphragm through which the wires are punched on being entered.

These meters are especially useful in such places as chemical factories, dye houses, and elsewhere, and, as they fill a great want, should find a large demand. They are made in all standard sizes up to 150 amperes, and all voltages up to 100 volts, for two wire system only, and are known as Type "T."

THE JOS. DIXON CRUCIBLE COMPANY.

THIS company have recently issued a new catalogue containing 36 pages and describing exactly 100 styles of their pencils, crayons and erasers. While no attempt at ornamentation has been made, the pamphlet is well printed and clearly illustrated with excellent wood cuts.

The Dixon Company own what are said to be the only successful graphite mines in America, situated at Ticonderoga, N. Y. They also own a large waterpower at the outlet of Lake George into Lake Champlain, where they have a mill six stories high and ninety feet square for the perfecting of their graphite.

WESTERN NOTES.

THE following new buildings in Chicago are being equipped throughout with okonite wire and interior conduit. Ellsworth Building, Teutonic Building, Boyce Building, Strickland Hotel, Columbus Building and Chicago Athletic Club.

The Central Electric Company, 118 Franklin street, are western agents for both of these products and report business very brisk and coming their way.

The Lundell motor also takes with the people and the outlook in this line is reported very promising.

F. G. Fuller, who for the past seven or eight years has been identified with the interests of the Edison machine works and the Edison General Electric Company, and for the past two years has held the position of western sales agent for the U. S. Wire & Cable Co., has resigned the above position, his resignation to take effect March 1st. After the above date Mr. Fuller's old friends will find him at Worcester, Mass., in the home office of the Washburn & Moen Mfg. Co. Mr. Fuller has accepted a lucrative position with the above company. His long experience in the cable line of the wire business means that the Washburn & Moen Co., have secured a most desirable acquisition to their representative force.

THE ELECTRIC APPLIANCE COMPANY are congratulating themselves on the way business has kept up through what is usually a very quiet month in the electrical supply line. They state that the demand for their standard specialties, among which might be mentioned Paranite Wire, Elkhart Transformers, Whitney Instruments, etc., continues to grow even when a quieting down of business might be expected. It should be mentioned with regard to the recent article in THE ELECTRICAL ENGINEER giving the allotment of space at the World's Fair that the Electric Appliance Company have secured a magnificent location several hundred square feet in extent and that they will make there a brilliant and notable display—one of the finest in Electricity Building.

D. B. MARTIN, general passenger and ticket agent of the three C's and St. L. railway company, better known as the "Big 4," is sending out some most desirable information to all parties contemplating a trip to the South.' Beyond doubt, the Big 4 possesses advantages not possessed by any other southern route. The company are dispatching magnificent solid vestibuled trains, steam-heated, equipped with palace sleeping cars, reclining chair cars and a thorough dining car service. In fact, everything is done to make this trip what is contemplated—a "Trip of Pleasure." Mr. Martin's headquarters are at Cincinnati in the large and handsome office building of the Big 4 company.

THE CENTRAL ELECTRIC COMPANY received an order last week by telegraph for 30 miles No. 4 weatherproof wire, the conditions of the accepting of the order being that it would be shipped on the same day. The order was filled out of its own stock, and the Central can be congratulated on being able to handle business of this magnitude in so prompt a manner. The Central Electric Company hope to have their new catalogue finished by April 1st, and beg the indulgence of their patrons, assuring them that they will be well repaid by waiting, as the book is expected to be the very finest in the catalogue art.

LOGANSPORT, IND.—The local *Daily Pharos* has a very appreciative item on the new plant of the Logansport Electric Light and Power Company and especially on the fine new 150 h. p. engine put in by the Ball Engine Company of Erie, Pa. The tests made by Mr. D. M. Seymour, of the Ball Company, with Messrs. Muir and Driftmeyer, for the Fort Wayne Company, were most satisfactory. The indicator cards were beautiful.

BUCKEYE LAMPS. The Chicago office of the Buckeye Electric Company is taking care of an immense amount of business, a large stock of standard voltage "Buckeye" lamps being carried at that point, which means prompt delivery, something duly appreciated by central station people.

THE RISDON IRON WORKS, of San Francisco, Cal., have been appointed Pacific Coast agents for De Rycke separators and grease-extractors manufactured by Joseph De Rycke, 145 Broadway, New York City.

DR. JOHN MCKINLOCK, has been appointed Medical Director in Chicago for the Commercial Alliance Life Insurance Company of New York.

MR. GEORGE CUTTER is back from an eastern trip during which he closed some large contracts for enamel rheostats and heating devices.

NEW ENGLAND NOTES.

PETTINGELL-ANDREWS COMPANY, of Boston, as stated recently in our columns, were recently appointed New England agents for the Siemens-Halske Company of America, and are making preparations to handle this business on a large scale. At a recent session of the Vermont Legislature, a charter was granted for a street railroad between Bellows Falls, Vt., and Paxton River village, a distance of five miles. A contract was closed and signed by the ten incorporators of the road, ceding their rights to the Pettingell-Andrews Company, who agree to build and have ready for use within two years, a substantial electric road between the two villages. Siemens-Halske apparatus will doubtless be used, and it is reported that the Pettingell-Andrews Company have a number of places where they will install Siemens-Halske apparatus as soon as they can get delivery from Chicago. The Pettingell-Andrews Company have now several very valuable agencies, and are rapidly increasing their business to a very large extent.

THE DAVIS ELECTRICAL WORKS, of Springfield, have issued a very neat little calendar for 1893, on which are represented some types of incandescent lamps, which they repair and claim to "make as good as new,"—perhaps better in certain instances. It is an important work, especially so in these days of incandescent lamp litigation, and everyone should familiarize himself with their method and prices.

THE BROWN ELECTRIC COMPANY, of Boston, have now got thoroughly settled in their convenient quarters at the corner of Summer and Federal streets, and have already done a most satisfactory business during the first month of their existence. "Salamander" wire, which this company sells in Boston and vicinity, has just been put on the list of wires accepted by the Boston Board of Fire Underwriters.

THE SAWTELL COMPANY, of Boston, the New England agents for the Davis Electrical Works of Springfield, who make a specialty of renewing burned out incandescent lamps, have removed their offices to room 10, Shawmut Building, 146 Franklin street. The location is more central for electrical business, and they will have more facilities for handling their rapidly increasing business.

THE CONSOLIDATED ELECTRIC MANUFACTURING COMPANY, of Boston, have recently issued a price list of arc lighting apparatus. They are now prepared to furnish arc dynamos of from 25 light to 90 light capacity, requiring from 20 to 42 h. p. The price list includes arc lamps, single and double carbon, and all other necessary apparatus for a complete arc lighting system.

MR. F. A. SWAN has succeeded to the business of Swan & Lane, and will hereafter conduct the business alone. Mr. Lane retires with the best wishes of all his friends, and Mr. Swan will doubtless continue to have the business support of all the old patrons of the firm, and carry on the business as successfully in the future as in the past.

CUMNER, CRAIG AND COMPANY, of Boston, have been appointed New England agents for the well-known Bishop high grade rubber insulated wires. All electricians will be glad to know that this wire is again represented in this territory, and that it is in efficient hands.

PHILADELPHIA NOTES.

THE COMMONWEALTH ELECTRIC COMPANY has removed from 606 Arch street to much more commodious quarters at 418 Market street where they will occupy the entire first floor and basement, In addition to the manufacture of dynamos and motors the company will do construction work and deal in general electrical supplies. They have met with remarkable success considering the short time they have been in existence. Mr. C. L. Crosby, their solicitor, is one of the most competent electricians in this section.

THE RIES ELECTRIC SPECIALTY COMPANY of Baltimore has been appointed sole agent for the sale of all the apparatus manufactured by the La Roche Electric Works for the states of Md., D. C., Va., W. Va., N. C. and S. C. Several installations have already been reported by this enterprising company.

THE PARTRICK & CARTER COMPANY now have their new Automatic Annunciator, illustrated in our columns not long since, ready for the market and they are filling the many advance orders received for them.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XV. FEBRUARY 22, 1893. No. 251.

WILLIAM WALLACE, AND HIS CONTRIBUTIONS TO THE ELECTRICAL INDUSTRIES.[1]—IV.

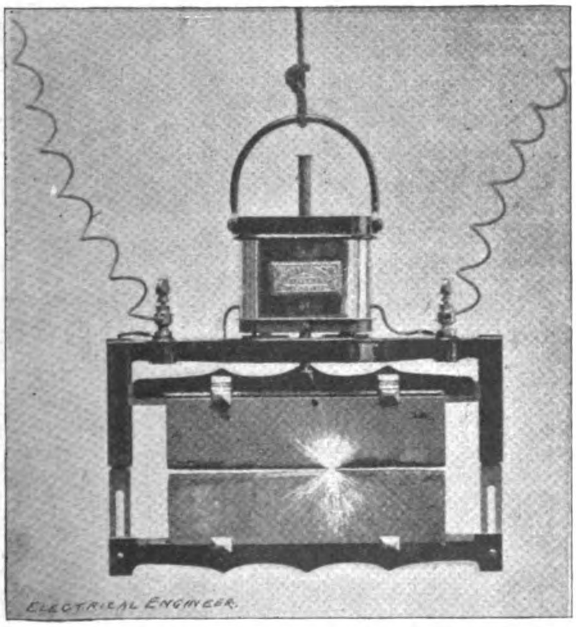
BY

Wm J Hammer

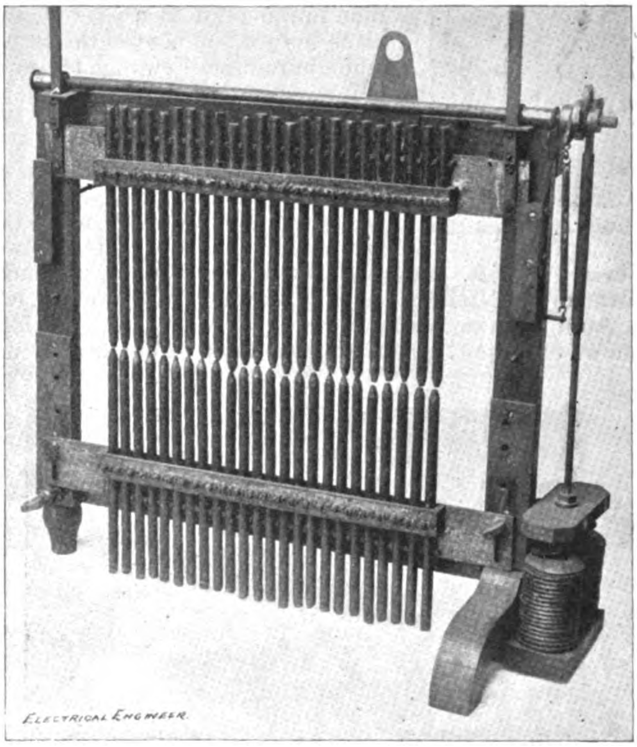
(Concluded.)

XI.

THE first installation in which arc lamps were run in series was made with the Wallace plate carbon lamps in his factory at Ansonia; and following this in the Fall of 1879, at the American Institute Fair, Mr. Wallace showed four and more lamps running in series. At this time Charles F. Brush, the well-known electrician, was inaugurating his work, and placed in the American Institute Fair four lamps run in separate circuits, and which shortly thereafter he succeeded in running in one circuit. At the Mechanic's Institute Fair, held somewhat later, a comparative test was made between the Wallace and Brush systems, and Professor Trowbridge, of Harvard College, awarded the medal to Mr. Wallace, stating in his report that the high resistance of the dynamo made it more suitable for running lamps in this manner. An interesting test was made at the Franklin Institute in Philadelphia under the auspices of Professors Thomson and Houston, who have since become so universally known through their electric lighting work. These tests were a comparison of the Gramme, Wallace and Brush machines, and it is claimed that they did not show as high an efficiency for the Wallace machine as they should have, due to the lack of knowledge at that time of the important relation of the resistance of the internal portion of the circuit as compared with the external. With the perfect knowledge and accurate character of the testing instruments which are in the possession of the electrical engineer to-day, it seems almost incredible that the early workers in the electric lighting field should have secured such splendid results as they did. Mr. Wallace informs me that their apparatus for testing the dynamos at the factory consisted of a galvanometer and a coil of iron wire, the usual test being that a dynamo should generate sufficient current to burn off a certain length of a given gauge of wire, or it was not up to the requirements, and the essential changes were made in the connections, windings, speed, etc.



Standard Wallace Plate Lamp.



Wallace's 48 Carbon Arc Lamp.

In the subsequent lamps the carbon plates were shortened and made much wider, and the upper, or positive, carbon, which consumed nearly twice as fast as the lower, was made considerably thicker and the edge became hollowed out where the crater formed and threw the light down. A lamp of this type is shown on this page. Mr. Wallace was the first man in the United States to undertake the manufacture of carbons, and claims that he invented the round pencil of carbon now so universally used, and the appli-

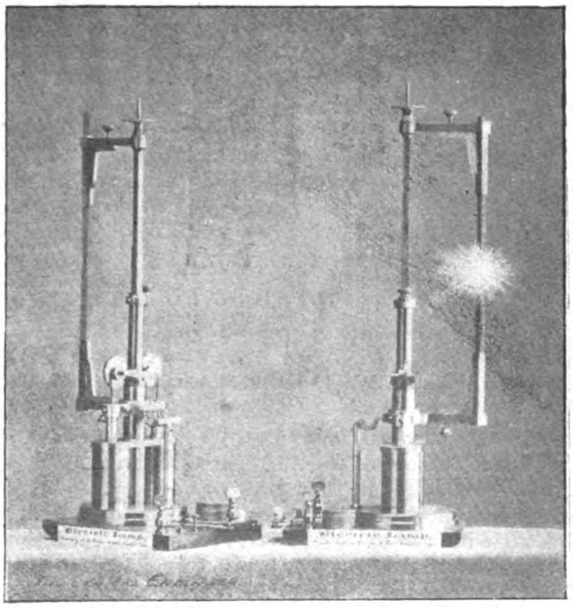
Wallace's 12 Carbon Lamp.

ances for producing the same, antedating Carré and others abroad. Up to the time of his experiments in this direction, all the carbons used in this country were imported and consisted of square pencils sawn from gas retort carbon, a tedious and expensive process. I believe the imported pencils cost 75 cents each; much better ones made to-day cost but half a cent each. The carbons were very impure and several saws would frequently be used up in cutting one stick or pencil. The great improvements in the arc lamps of to-day are far more due to the improvement in carbon manufacture than in the perfection of the apparatus to feed and control the carbons while burning. Few men to-day are better posted in the details of carbon-manufacture than William Wallace. He erected an immense plant at the works of Wallace & Sons, capable of turning out 40,000 carbons per diem, and many of the tools and processes employed to-day were devised by him. Subsequently he disposed of the carbon plant to the National Carbon Company, of Cleveland, O.

An interesting modification of the Wallace plate lamp is shown on page 179, in which no fewer than 48 carbon pencils were employed, 24 above and 24 below, the arc moving from pencil to pencil as they burned away, and the feed being controlled by the magnet shown, in a manner somewhat similar to the plate lamp. This lamp was constructed in 1877. He also built a "V" lamp having two carbons above and one below.

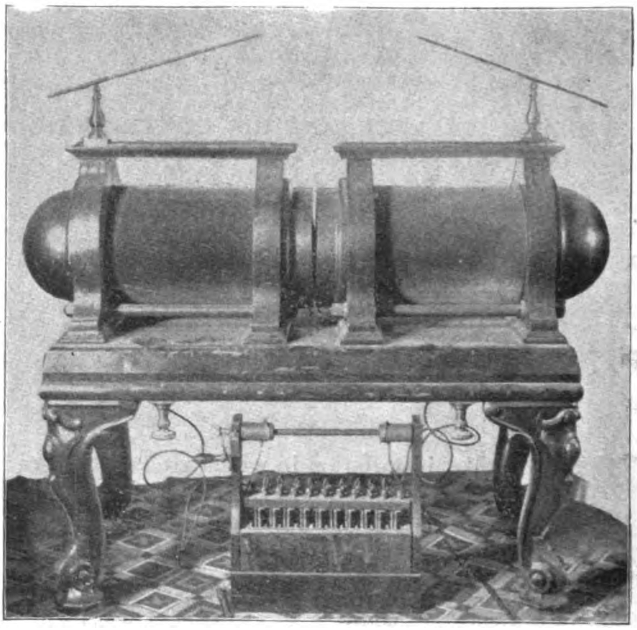


WALLACE'S IMPROVED CARBON PENCIL LAMP.

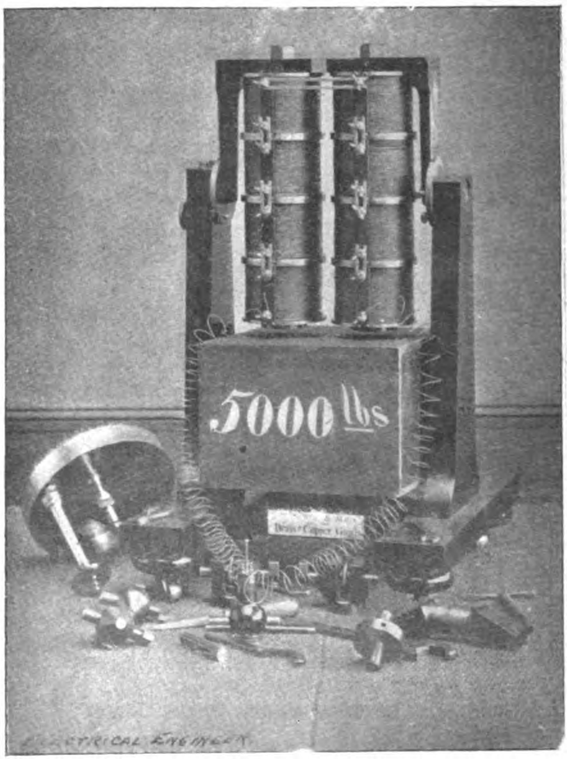
Other types of lamps are shown on this page. One of these is a twelve carbon lamp, six carbons being mounted upon both the upper and lower rings. This lamp is still in use to-day in lighting Mr. Wallace's private laboratory and works very satisfactorily.

XII.

The great Wallace induction coil, of which an illustration is presented on this page, is the largest induction coil ever made in this country, and, with the exception of the great Apps or Spottiswood coil in England, is the largest in the world. It was begun by Mr. Wallace in 1869 and completed in 1871. It is over five feet in length and twelve and a half inches in diameter, and with its condenser weighs over fourteen hundred pounds. It will give a 27-inch spark with a small battery of 6 Grove cells. The secondary coil consists of 95 miles of No. 36 B. & S. gauge wire. It was wound in sections like very narrow rolls of ribbon, so that no two portions of the wire of great difference of potential would come near together, a method often credited to Ritchie of Boston, who, however, only modified the plan probably first suggested by Poggen-

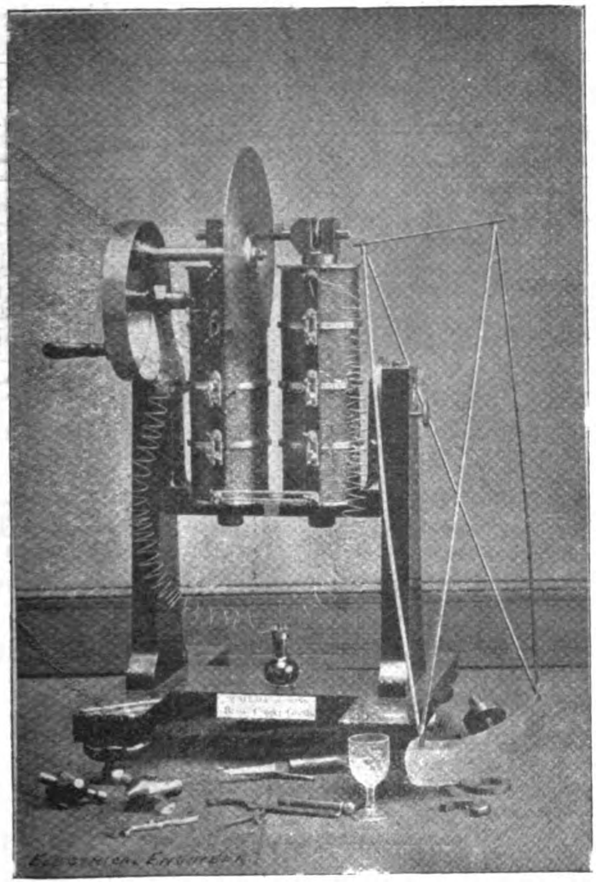


THE GREAT WALLACE COIL.



WALLACE MAGNETS.

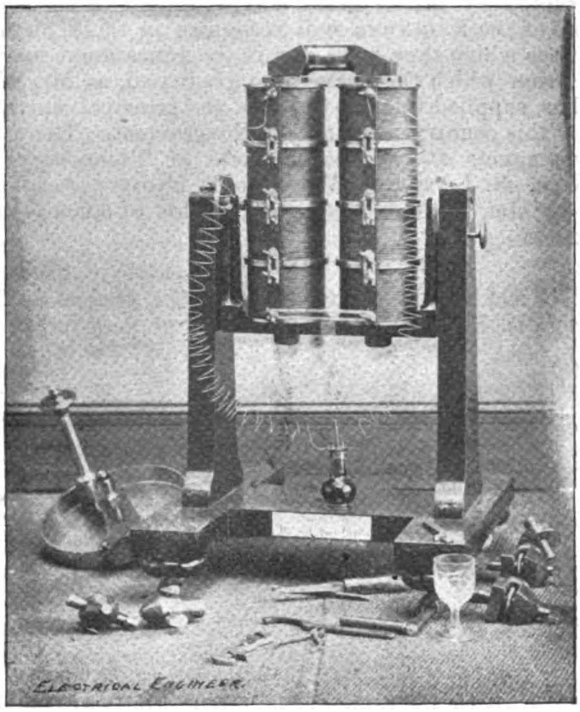
dorff in 1854, although two years previously Charles and and Edward Bright, of England, patented a similar method of winding electro-magnets. Almost the entire winding of these coils and the construction of the paraffine sheets and tin-foil for the condenser was done by Mr. Wallace's wife and his daughter Eloise, the winding being done upon a sewing machine rigged up for the purpose. Nearly three years were occupied in the construction of this immense coil and many interesting experiments were conducted by Mr. Wallace and others with it, until during some tests to determine the maximum spark which the coil was capable of producing, the insulation of the secondary was pierced and the coil damaged. The coil is still in existence in Mr. Wallace's private laboratory, and will give a considerable spark, although nothing like its original capacity. Mr. Wallace believes that it would be impossible to repair this break without unwinding much of the coil, but its efficiency might be increased by immersing the entire coil in oil. I have been informed from a reliable source that a similar accident has happened to the celebrated Apps coil referred to, which at one time would give a spark 42 inches in length with a battery of 30 Grove cells. The coil was 37.5 inches long, 20 inches in diameter and weighs alone 1,500 lbs. The wire in the secondary was 280 miles in length, and the total number of turns 341,850. It was completed in 1876. Doubtless the recent work of some of our scientific men, notably that of Prof. Elihu Thomson, precludes the possibility of the construction of large coils of this type hereafter.



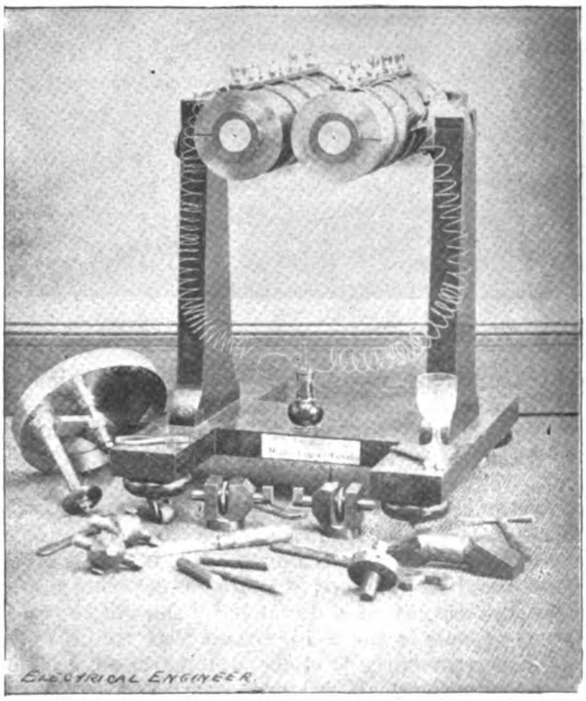
Wallace's Experimental Apparatus.

XIII.

In storage battery work Mr. Wallace and his brother Thomas have spent a large amount of time and money, though, like many other workers in this field, the results have been sadly disproportionate to the outlay. In conjunction with Prof. A. K. Eaton, the well-known chemist, they took out a large number of patents for improvements in storage or secondary batteries. These had mainly to do with mechanical modifications, but the feature which seemed most promising was the treatment of red lead, or minium with acetic acid which dissolved the lower oxide and formed the higher oxide, acetate of lead. For the other electrode a plate of zinc was used upon which lead was deposited in a spongy form. It was thought that this arrangement would do away with the tedious process of forming the plates, and yield really a primary secondary



Wallace's Experimental Apparatus.



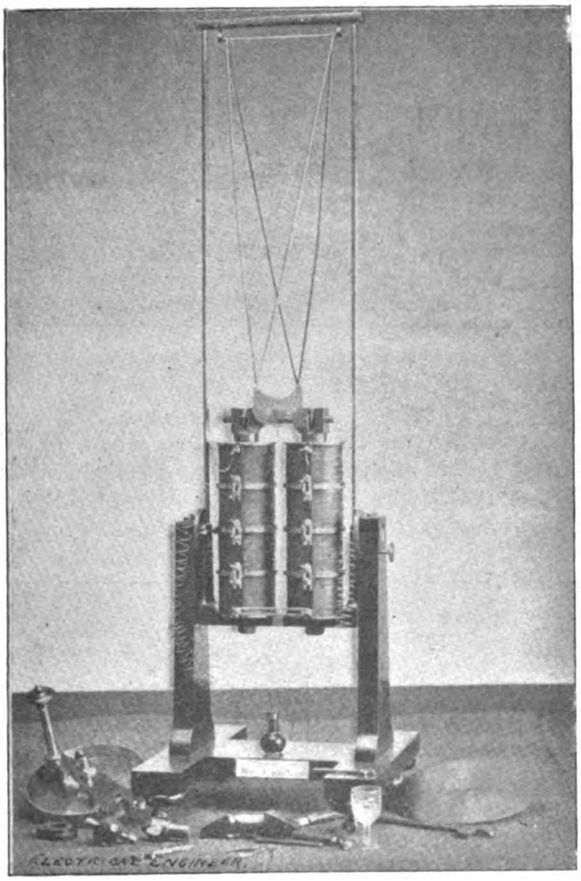
Wallace's Experimental Apparatus.

cell, but it did not realize the expectations of the inventors.

On this and preceding pages are shown sets of apparatus for experiments in magnetism and electricity, devised and constructed by Mr. Wallace, and doubtless many of the readers of the ENGINEER will recognize in these pictures apparatus which they have seen in the educational institutions from which they have been graduated, as Mr. Wallace has supplied them to many of the principal universities of this country and to the Government. The great electromagnets at Stevens Institute of Technology, at Hoboken, N. J., and at West Point Military Academy, made by him, are able to support weights of 5,000 pounds and more.

XIV.

It is a fact well-known to many of the readers of THE ELECTRICAL ENGINEER that a number of very important patents taken out by inventors in this country which have led to expensive litigation and claims of priority by various inventors, have been given their quietus through the discovery that these inventions were anticipated by the work of William Wallace and his assistants. A notable instance is the arc lamp clutch mechanism claimed by Mr. Chas. F. Brush, found to have been first used in the Wallace lamp at the suggestion of Mr. Leroy White of Waterbury; and the claim of Mr. Edison covering the controlling of the output of a dynamo by the putting-in and cutting-out of coils in the field circuit was found to have been applied to an early Wallace dynamo used, I believe, for plating purposes. It is interesting furthermore, to speculate on the effect which would have been produced upon the electric lighting industry had Wallace patented his arrangement of arc lamps in series. Certainly the fame and finances of this most deserving pioneer in the electrical field would have been greatly enhanced thereby.



WALLACE'S EXPERIMENTAL APPARATUS.

In conclusion the writer would state that Mr. Wallace is a member of the Institute of Electrical Engineers, of the American Society of Mechanical Engineers, of the Society of Civil Engineers, the Association for the Advancement of Science, and many other scientific organizations.

THE THEORY OF SUBMARINE CABLE LAYING.—II.

BY

GWLittlehales.

(Concluded.)

The following table gives the value of the holding power to be applied to the brake for depths of the sea increasing from 440 to 2,660 fathoms and for speeds ranging from 2 to 10 knots per hour, the constants of the cable being the same as those used in forming the preceding table:

Depth in fathoms.	Hold, *f*, to be applied to the brake for velocities of the ship per hour of					*ph*.
	2 Knots.	4 Knots.	6 Knots.	8 Knots.	10 Knots.	
	lbs.	lbs.	lbs.	lbs.	lbs.	lbs.
440	919.6	874.8	802.7	701.9	572.4	1007.9
890	1839.2	1749.6	1605.4	1403.9	1144.8	2015.9
1330	2758.9	2624.4	2408.1	2105.8	1717.1	3023.9
1780	3678.4	3498.9	3210.8	2807.8	2289.5	4031.6
2220	4597.9	4373.9	4013.5	3509.7	2861.8	5039.8
2660	5517.7	5248.5	4816.2	4211.7	3434.4	6047.5

The angle β, which determines the effective motion of each element of the cable, is easily calculated by the relation

$$\tan\beta = \frac{\mathrm{ED}}{\mathrm{EC}} = \frac{v\sin\alpha}{v\sin\alpha\tan\frac{\alpha}{2} + mv} = \frac{1}{\tan\frac{\alpha}{2} + \frac{m}{\sin\alpha}};$$

or, substituting in the denominator, its value as derived from equation (8),

$$\tan\beta = \frac{v}{t}\ \frac{ph}{ph - f} \qquad (12).$$

From equation (8),

$$m = \frac{ph - f}{\frac{v}{t}\,ph}\sin\alpha - \tan\frac{\alpha}{2}\sin\alpha$$

$$= \frac{t\,(ph - f)}{vph}\sin\alpha - 2\sin^2\frac{\alpha}{2} \qquad (13)$$

$$= \cot\beta\sin\alpha - 2\sin^2\frac{a}{2}.$$

The angle of immersion, α, being generally small, as soon as the speed of the ship becomes considerable, $\sqrt{\cos\alpha}$ can be neglected in equation (7), and the following relation may be written to serve for practical use:

$$\tan\alpha = \frac{u}{v}.$$

To show that the error so introduced may be neglected, the angle α is here calculated from each of the formulas for the kind of cable already considered and for speeds of the ship ranging from 2 to 10 knots.

α	Speed of Ship.				
	2 kn.	4 kn.	6 kn.	8 kn.	10 kn.
Calculated from equation (7)...	51°-50′	28°-05′	18°-55′	14°-15′	11°-25′
Calculated from equation (14)..	45°-00′	26°-34′	18°-26′	14°-02′	11°-19′

From this table it appears that as soon as the ship acquires a speed of 6 knots per hour, which is about the average speed of ships while engaged in cable laying, the values of the angle α calculated from equations (7) and (14) are so near alike that in practice (14) may be substituted for (7).

If the trigonometric functions of α be now expressed according to equation (14), neglecting terms containing the factor $\frac{u}{v}$ raised to powers higher than the second, we shall have

$$\sin \alpha = \frac{u}{v}, \qquad \tan \frac{\alpha}{2} = \frac{u}{2\,v}, \qquad \sin \frac{}{2} = \frac{u}{2\,v}.$$

Substituting these values in equations (8), (11), and (13), they become :

$$f = ph\left(1 - \frac{u}{2\,t} - m\,\frac{v^2}{u\,t}\right) \tag{15}$$

$$P = ph\left(1 - \frac{u}{2\,t}\right) \tag{16}$$

$$m = \left(\frac{ph - f}{ph} \times \frac{u\,t}{v^2}\right) - \frac{1}{2}\,\frac{u^2}{v^2} \tag{17}$$

We see by the last of these equations that the slack of the cable is inversely proportional to the square of the velocity of the ship. The first two terms of the second member of this equation being much greater than the other; we see, moreover, that the slack depends above all on $ph - f$, that is to say, upon the difference of the weight of the length of the cable which may be suspended vertically in the water from the ship to the bottom of the ocean and the retaining force exercised by the brake. Therefore, the slack may be changed either by acting on the brake or by altering the speed of the ship.

To investigate the effect upon the slack of changes in the retaining force of the brake, in the speed of the ship, and in the depths of the ocean where the cable is laid, let us differentiate m in equation (17) with reference to f, v, and h successively:

$$\frac{d\,m}{d\,f} = -\,\frac{u\,t}{ph\,v^2}$$

$$\frac{d\,m}{d\,v} = \left(u\,t - \frac{f\,u\,t}{ph} - \frac{u^2}{2}\right) \times -\,\frac{2}{v^3} = -\,\frac{2\;m}{v};$$

$$\frac{d\,m}{d\,h} = \frac{f\,u\,t}{p\,v^2} \cdot \frac{1}{h^2} = \frac{f\,u\,t}{p\,v^2\,h^2}$$

Whence

$$d\,m_f = -\,\frac{d\,f}{f} \cdot \frac{f\,u\,t}{p\,h\,v^2} \tag{18}$$

$$d\,m_v = -\,\frac{d\,v}{v}\,2\,m \tag{19}$$

$$d\,m_h = \frac{d\,h}{h}\;\frac{f\,u\,t}{p\,h\,v^2}. \tag{20}$$

It is to be remarked that, as the second member of equation (19) is independent of the constants of the cable and of the depth of the ocean, the first member depends only on the variable velocity of the ship. For instance, if the velocity of the ship were increased by 5 per cent., the slack would be diminished by $\frac{1}{10}$ of its value and would fall to nine per cent. if it had before been 10 per cent.

Again, as the same expression, $\frac{f\,u\,t}{p\,h\,v^2}$, is found as a factor in the second members of (18) and (20), the slack will vary by equal amounts but in opposite directions for the same proportional changes in the retaining force of the brake and in the depth of the ocean. Referring again to the cable whose constants are $p = 0.336$ pounds to the foot, $t = 22.96$ feet per second, and $u = 3.28$ feet per second, and supposing the cable to be laid in a depth of 1,780 fathoms with 10 per cent. of slack and at a speed of 6 knots an hour, we shall find by equation (15) that the retaining force of the brake must be 3,280 pounds.

Under these conditions equations (18) and (20) give

$$d\,m = -\,0.62\,\frac{d\,f}{f} \text{ and } d\,m = 0.62\,\frac{d\,h}{\mathrm{h}}.$$

If the depth increases five per cent., say 90 fathoms, the slack will be increased by $\frac{31}{100}$ of its previous value or will rise from 10 per cent. to $13\frac{1}{10}$ per cent. To keep it at 10 per cent., it will be sufficient to increase the retaining force of the brake in the same proportion as the depth has increased, that is to say, five per cent. or 164 pounds. Moreover, changes in the depth and in the brake-power vary the amount of slack in a more rapid proportion than changes in the velocity of the ship, and it is found preferable in practice to control the amount of slack by acting on the brake.

If a cable were laid without any brake, we would have for the slack, by putting $f = 0$ in equation (15),

$$m = \frac{1}{2}\,\frac{u\,(2\,t - u)}{v^2}.$$

With $u = 3.28$ feet per second, $t = 22.96$ feet per second, and $v = 6$ knots per hour, m would become equal to 72 per cent. To maintain it at 10 per cent., the velocity of the ship would have to be increased in such a way that

$$v = \sqrt{\frac{u\,(2\,t - u)}{2 \times \frac{1}{10}}},$$

which would lead to the almost impracticable speed of 16 knots per hour. But by changing the constants of the cable, and making $u = 1.64$ feet per second, $t = 13.12$ feet per second, and $m = 10$ per cent., the speed of the ship would be about $8\frac{1}{2}$ knots per hour which is easily maintained.

LAMINATED OR DIVIDED IRON AND OTHER METALLIC MASSES IN ELECTROMAGNETIC APPARATUS—VIII.

BY

Thos D Lockwood

(Concluded.)

SUPPLEMENTARY NOTE ON PARASITIC CURRENTS.

Since the main object of laminating or otherwise dividing cores and other metallic masses exposed to induction, is to break up circuits, within which parasitic induced currents might circulate and waste energy, a supplementary note on such currents does not appear out of place.

Until a comparatively recent date, these were by many persons, (albeit quite erroneously) termed Foucault-currents. In the early days of electromagnetism the experiments made by the different investigators were so interlaced and interlocked, that it is difficult to tell where or with whom special phenomena, afterwards elucidated, did in fact originate. It is for example now quite evident that the so-called "magnetism by rotation" of Arago was simply an instance of magneto-electric induction.

If the parasitic currents, alias "eddy-currents", alias "Foucault-currents" should bear the name of any one, it would appear that an association with that of Arago is the most appropriate.

It was in 1824 that Arago, studying the oscillations of a magnetic needle, first ascertained that when such a needle was caused to oscillate above non-ferruginous conducting surfaces, it began, when left to itself, to oscillate in arcs of continuously decreasing amplitude, as if it had been placed in a resisting or viscous medium; and it was further observed that the diminution in the length of swing did not alter the number of oscillations that were performed in a given time, and that it varied with the distance between the needle and the surfaces.

For this discovery, the Royal Society of London awarded Arago its Copley medal, and he has the honor of being the first foreigner receiving this award. His experiments led him to believe that the needle would be dragged along by rotating the metal plates which had the power of diminishing the amplitude of its oscillations, and upon trying the experiment this conjecture was shown to be correct. This discovery closely followed the former and analogous one. A plate of pure copper was caused to revolve by clockwork which also was of copper, under a magnetic needle within a glass receiver, and with a sheet of paper between the needle and the revolving plate to prevent air currents. Gradually the needle was drawn from the magnetic meridian, till finally on a very rapid rotation, it fairly swung round and continued in constant rotation.

Arago also noticed (and here we have rudimentary lamination) that when the plates had portions cut out in the direction of the radii, their action on the needle was diminished. An account of these experiments was read before the Academy of Sciences, March 7, 1825.

Barlow (*Phil. Trans.*, 1825), Herschell, Seebeck (*Pogg. Ann.*, 1826), Babbage (*Phil. Trans.*, 1825), and Harris (*Phil. Trans.*, 1831), made elaborate researches on the subject, and it is noteworthy that both Babbage and Herschell also found that the number of revolutions performed by the disc in a given time was greatly affected by cutting the plate through in the direction of the radii, the accelerating forces diminishing with the number of slits made; ("Treatise on Electricity," De La Rive, Vol. i., 1853, p. 351).

Poisson (Mém. de l'Acad., vii., 1826), attempted in his memoir on magnetism to give a theoretical explanation of the phenomena, but it was reserved for Faraday to point out the true explanation, for, as we now know, Arago produced true magneto-electric currents, although he knew it not. Faraday's considerations on the phenomena, together with a full account of the experiments by means of which he in 1831, reached the conclusion that Arago's rotations were the results of the development of magneto-electric currents, are all detailed in the "Experimental Researches" (Series i., §§. 80 to 139, Vol. i., pp. 24–41); beginning by the statement that induction "appears capable of explaining fully the remarkable phenomena observed by M. Arago between metals and magnets when either are moving, as well as most of the results obtained by Sir John Herschell, Messrs. Babbage, Harris and others;" and discussing the action of the rudimentary laminations of Arago, Babbage and Herschell, in § 127.

Some years later, Plücker suspended a cube of copper between the poles of a powerful electromagnet and setting it spinning about a vertical axis, found that it stopped dead the moment the magnet was excited.

It was not, however, until September 1855, that Leon Foucault made the experiment which, though sufficiently interesting, was quite inadequate in view of what had gone before, to warrant the attachment of his name to parasitic magneto-electric currents. He arranged a flat copper disc between the flat poles of an electromagnet placed at such a distance apart as just to admit it between them. The disc was set in motion by means of a suitable driving gear. So long as the magnet was not excited, the driver had comparatively little work to do; but as soon as the magnet was excited the work required to keep up any considerable velocity greatly increased. The additional work thus expended appears in the heat developed in the disc by the induced currents.

Foucault's real discovery then, was that the force required for the rotation of a copper disc moving in its own plane becomes greater, the disc at the same time growing hotter, when the disc is made to rotate with its rim between the poles of a horseshoe magnet; and his account of it is recorded in the *Comptes Rendus* of that year.

The only further experimental investigations of this subject, of which I am informed, are those of Nobili and Matteucci which are to be found in *Wiedemann*, Bd. 2, § 860, etc.; and as for its theoretical treatment the reader is referred to *Crelle's Journal*, 1864; and *Pogg. Ann*, 1864, where Jochmann's mathematical theory is stated; and to Maxwell's complete and masterly theory of the induction of currents in a plane conducting sheet, reached by means of a most elegant application of the method of images; *Proc.* R. S., 1872; "Electricity and Magnetism," vol. 2, §§ 668, 669.

INFLUENCE OF FREQUENCY ON THE WORKING OF ALTERNATE CURRENT TRANSFORMERS.—I.

BY

Chas. Steinmetz.

Taking into consideration the number of turns and the resistances of primary and of secondary circuit, from the dimensions of the magnetic circuit, its characteristic and coefficient of hysteresis, the behavior of the alternating current transformer under the various conditions of load and of frequency can be calculated with a high degree of exactness, as is well known. To determine, however, how far calculation agrees with observed results, and whether Foucault currents, etc., play an important part, and especially, whether such a thing as *viscous hysteresis* exists—which, as is known, in calculations is assumed as non-existent, but which, if present, would introduce a serious error into the calculations,—I undertook some time ago a number of tests with a small Westinghouse transformer (voltmeter converter) of about 500 watts output, with largely varying frequencies, of 36.3, 137.5 and 204.5 complete periods per second.

Since the amount of stray magnetism, or magnetic leakage between primary and secondary coil, was of no importance for the object of this research,—it being understood that by proper arrangement of primary and secondary winding the stray magnetism can be reduced to practically nil,—and since the hysteretic loss has been proved to be independent of the load, and only dependent on the magnetization, it was sufficient to make only open circuit tests, and therefrom to calculate, by means of the known resistances, the conditions for working under load.

The alternating current was derived in the high frequency tests (137.5 and 204.5 periods) from a 1 h. p. 50-volt Westinghouse dynamo, which was varied in E. M. F. by varying the exciting current, and driven by a continuous current motor. In the low frequency tests (36.3 periods) the alternating current was derived from a continuous current Eickemeyer motor, which by means of two sliding rings was converted into a bipolar alternator.

The transformer was an old Westinghouse voltmeter converter of the following description:—Primary circuit: 900 turns No. 25 B. & S. gauge, 52 ohms resistance. Secondary circuit: Two coils of 45 turns No. 14 B. & S. gauge, of .21 ohm resistance each. One of these coarse wire coils was used for the excitation, and fed by the alternator.

The dimensions of the magnetic circuit were:—Average cross-section, 40 cm.^{2} Average length, 22 cm. Thickness of iron plates, about .03 cm.

The method of determination was the usual three-electro-dynamometer method, with long shunt, that is: Ammeter and coarse wire coil of wattmeter were connected in series to the transformer coil, voltmeter and fine wire coil of wattmeter in long shunt around transformer and instruments, so that in determining the voltage at the transformer terminals correction had to be made for the E. M. F. consumed by ammeter and coarse coil of watt-meter; and in determining the iron loss of the transformer the wattmeter readings had to be reduced by the power consumed by the resistance of transformer coil and instruments, which correction, however, was only small, except for the highest readings with 36.3 periods, in which readings, owing to magnetic saturation, the current and consequently the resistance loss were very large and even larger than the iron loss, so that the exactness of these higher readings is somewhat impaired by the uncertainty of the resistance due to the high temperature coefficient of copper, a defect which is incident to this method, as explained elsewhere.[1]

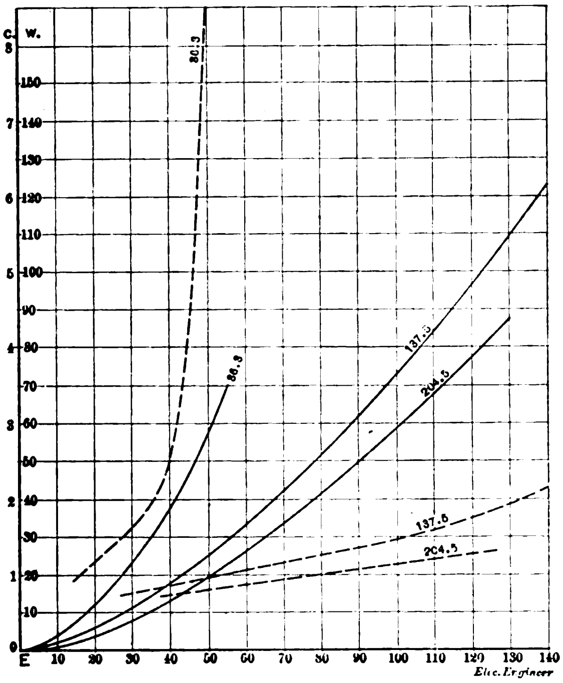


FIG. 1.

The results of these tests were plotted in curves, and are given in Fig. 1. As abscissæ there are used the E. M. F.'s in effective volts at the terminals of the coarse wire coil of the transformer (of 45 turns) which was fed by the alternator. As ordinates are given in drawn lines, the losses in the iron of the transformer (hysteresis and probably eddy-currents), in watts, for 36.3, 137.5 and 204.5 periods per second. As dotted curves are given the magnetizing currents, corresponding to the different frequencies and E. M. F.'s, in amperes effective. Multiplied by 45, the number of turns of the excited transformer coils, these magnetizing currents give the M. M. F's in ampere turns effective.

As seen from Fig. 1, the loss in the iron, corresponding to a given E. M. F., is the larger, the lower the frequency is, and the magnetizing current or "leakage current" (current on open secondary) is larger for slower frequencies, and increases, for a given frequency, with increasing E. M. F.; but slower than the E. M. F. increases, up to a certain point, where the current curve turns around abruptly and rapidly increases, quite out of proportion.

If the fine wire coil is used as primary, the "leakage" or magnetizing current will be 20 times smaller. Hence, for instance, at a frequency of 204.5 the magnetizing current at 50 volts secondary is .040 ampere primary, or .80 amperes secondary; at 100 volts secondary, it is only .056 ampere primary or 1.12 ampere secondary; while with a frequency of 36.3, the magnetizing current is: At 27 volts secondary, 1.5 ampere secondary, or .075 ampere primary; at 54 volts secondary, 24 amperes secondary, or 1.2 ampere primary. So that in the first case, doubling the E. M. F. increases the current only 40 per cent. In the second case, doubling the E. M. F. increases the current by not less than 1,500 per cent., saturation being reached.

A SIMPLE SYSTEM FOR OPERATING ELECTRIC CLOCKS.

BY

R. G. Brown

How many of us have made an electric clock, a clock to be actuated by a small battery controlled by a central or primary clock,—made them to have in operation at our homes as a novelty, to show to our friends, and yet, how many such clocks are to be relied upon for correct time?

It would seem, at first thought, an easy problem to arrange a small device attached to an ordinary clock that would open and close once each minute an electric circuit, and yet, in practice to accomplish this result in a reliable manner with an ordinary cheap movement, has puzzled many.

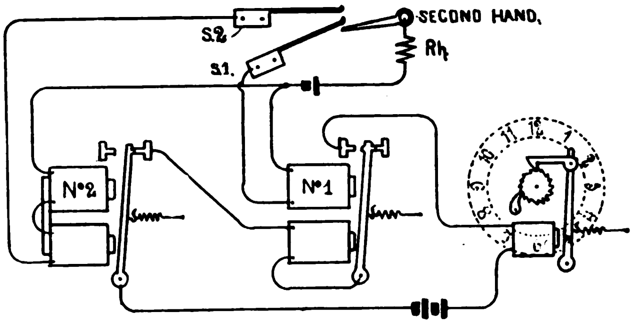
With a clock beating seconds the problem is comparatively easy, but such a clock requires a pendulum 32 inches in length, and is an expensive affair possessed by few. All cheap clocks make, on an average, 240 beats per minute and this is the cause of the trouble, for the reason that the second hand, moving so short a distance at each of the 240 beats, it is almost impossible to adjust a spring in such manner that the second hand will halt just before reaching the spring, and at the next beat move in contact with it, and again at the next beat move free from it. It must also be borne in mind that very little work can be put upon this second hand.

The system to be here described has been in use by the writer for some time past and can be depended upon for reliability. Its action is a decided open and shut, with the result that the secondary or electric clock cannot "jump" ahead or lag behind.

Briefly, it consists of a Seth Thomas No. 2 movement (costing $1.50 complete), two ordinary pony relays and three cells of Leclanché battery.

This clock has a second hand, in the path of which are arranged two light flat springs. The spools of the No. 1 relay are separated so as to be connected in independent circuits. Referring to the accompanying diagram, the operation is as follows: As the second hand comes in contact with the first spring—s1, the No. 1 relay armature is drawn against its front stop, thereby closing a circuit in which is included one of its own magnets, armature and back stop of the No. 2 relay, electric clock and two cells of battery

It may here be remarked that this circuit is not closed until the armature has actually reached its front stop and that after having reached there it is held in this position by one of its own magnets, and quite independent of the circuit closed by the primary clock; so that, however uncertain this latter contact may have been made or broken, there can be no false make or break in the circuit containing the electric clock.



BROWN SYSTEM OF ELECTRIC CLOCKS.

As the second hand of the primary clock leaves the No.

---

[1] On the Law of Hysteresis.—II." *Transactions Am. Inst. Elec. Eng.*, Sept., 1892.

1 contact, this No. 1 relay still remains closed and will so remain until the hand comes in contact with the spring s2, thereby closing the No. 2 relay, whose armature, being drawn away from its back stop, opens the electric clock circuit, thereby causing the No. 1 relay armature to fall back on its insulated stop, thus leaving the electric clock and battery on open circuit until the second hand has made a complete revolution, when the whole operation will be repeated.

The two springs, s1 and s2, are arranged rather close together, with the result that the whole operation is completed in less than two seconds ; consequently during each minute we find the batteries are closed through resistances during 2 seconds, and are on open circuit the remaining 58 seconds. The Leclanché battery will work perfectly for a long time under these conditions.

The relays used by the writer have a resistance of 20 ohms each, and a small resistance of about 20 ohms is put in circuit with them, as shown. In the clock circuit proper, this is not necessary, as the circuit is closed barely a second per minute.

ON DISTRIBUTION OF POTENTIAL.

BY

George P. Huhn.

The following is a short and direct method of obtaining a sine curve, whose ordinates shall show the distribution of potential around the commutator, when we have plotted the integral curve and v. v.

The expression for the integral curve is

$$\int_0^{\alpha} \sin \theta \, d\,\theta = 1 - \cos \alpha.$$

The expression for the sine curve is $x = \sin \alpha$. Then if we call any ordinate of the integral curve a, and any ordinate in the sine curve x we have:

$$a : x :: 1 - \cos \alpha : \sin \alpha ; \ \frac{\sin \alpha}{1 - \cos \alpha}\, a = x.$$

Let us introduce into our formula a constant quantity k and we will have :

$$\frac{\sin \alpha}{1 - \cos \alpha}\, a\, k = x.$$

k, being a constant, affects only the absolute, not the relative values of the ordinates in the sine curve. For convenience I leave $1 - \cos \alpha$ in this form rather than writing vers α.

The average sine between 0 and 90° is $\frac{2}{\pi}$ (see Kapp) and is obtained as follows.

$$\frac{\int_{0^\circ}^{90^\circ} \sin \theta \, d\,\theta}{\theta} = \frac{1}{\frac{1}{2}\pi} = \frac{2}{\pi}.$$

Let Fig. 1 be any integral curve as plotted from our readings and let Fig. 2 be the sine curve derived from it by the formula

$$\frac{\sin \alpha}{1 - \cos \alpha}\, a\, k = x.$$

To find the value of k we proceed as follows :

The ordinate a'' (Fig. 1) represents the sum of the E. M. F.'s induced in all the commutator bars, n in number, which lie between 0 and 90°. If our plotted curve were an ideal integral curve the E. M. F. in any one bar would be proportional to the sine of the angle through which that bar had turned.

The average sine between 0 and 90° is $\frac{2}{\pi}$ and if all the commutator bars had been at this point the sum of the E. M. F's would have been the same. Therefore, dividing the total E. M. F. at 90° by n we will have $\frac{a''}{n}$ = E. M. F. induced in one bar at $\sin^{-1} \frac{2}{\pi}$ for an ideal integral curve with a'' as the ordinate at 90°.

But in our sine curve (derived from this ideal integral curve) we wish to have $x' = \frac{a''}{n}$, in order that each ordinate in the sine curve may show the E. M. F. induced in one bar at that angle. But this will be accomplished if we make the ordinate at 90° equal to $\frac{a''}{n} \cdot \frac{\pi}{2}$. And since our ideal curve is so drawn that the ordinate at 90° is equal to the ordinate at 90° in our plotted curve, we may, in our plotted curve, make

$$x'' = \frac{a''}{n} \cdot \frac{\pi}{2}.$$

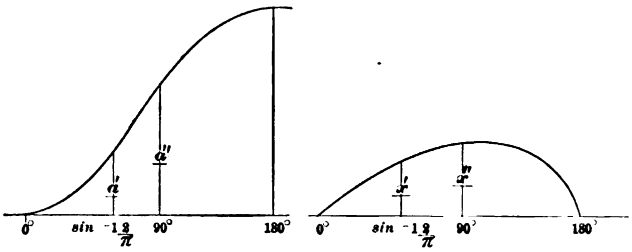
Substituting in the formula we have :

$$\frac{\sin \alpha^{90^\circ}}{1 - \cos \alpha^{90^\circ}}\, a^{90^\circ}\, k = x'' = \frac{a''}{n} \cdot \frac{\pi}{2}.$$

$$\therefore a^{90^\circ} k = \frac{a''}{n} \cdot \frac{\pi}{2} ; \ k = \frac{\pi}{2\,n}.$$

And since k is constant for all values of α and a, we have the formula :

$$\frac{\sin \alpha}{1 - \cos \alpha}\, a.\, \frac{\pi}{2\,n} = x ;$$



FIGS. 1 AND 2.

in which x is the absolute value of the E. M. F. induced in one bar at its angle.

V. V. Having the sine curve plotted, we may find the integral curve by writing the above formula

$$a = x.\, \frac{1 - \cos \alpha}{\sin \alpha} \cdot \frac{2\,n}{\pi}.$$

"COMPLETE REPORTS AND COMMENTS."

The February 2 number of *Metal* constains the following in regard to the present "celebrated case" and, incidentally, the ENGINEER :

"Nearly every business man to-day, especially in the large cities, uses the electric light, and anything pertaining to this important means of illumination will be of interest. The latest developments in the incandescent lamp litigation shows a new claimant for priority to the invention in the person of Henry Goebel, a resident of New York, who has made affidavits and shown lamps on this principle, made in 1859, long before Edison ever thought of such a thing as an electric light. Our able contemporary, THE ELECTRICAL ENGINEER, has shown a deal of enterprise in giving a full and detailed statement of the proceedings in Boston, and supplements this with a fully illustrated article on the life and inventions of Goebel in this line. We congratulate THE ELECTRICAL ENGINEER on its keen insight in filling the demand of its readers by giving, in advance of the other electrical publications, such complete reports and comments."

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed, and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XV. NEW YORK, FEBRUARY 22, 1893. No. 251.

SHALL WE STORE CURRENT OR CALORIC?

ELECTRICAL engineers have scarcely had time to test to a finality the value of storage batteries in central station work when they have already brought to their attention another method of storage which, if not designed to accomplish exactly the same purpose, is at least brought forward as a possible substitute. We refer to the scheme for heat storage due to Mr. Druitt Halpin, to which Prof. W. C. Unwin has recently drawn attention in a lecture before the Society of Arts. Based upon the consideration that even in the best managed electric central stations, the full consumption, due to fluctuations in load, is double that required to do the work at full load, Mr. Halpin was persuaded that the larger part of the waste was to be traced to the irregular action of the boilers, and that if the latter could be worked continuously and uniformly and the heat in excess of that required at any one time stored to be drawn upon when needed, this waste could be prevented. For this purpose he proposes a system in which for each pound of steam used, 16 pounds of water is heated to 406 degrees at an absolute pressure of 265 pounds per square inch, the water at the end of the operation being at a temperature of 367 degrees ready to be heated to 406 degrees again. The heated water is stored in a tank which is in free communication with the boiler; but instead of keeping the water level in the boilers constant, as usual, the water level in the storage tanks is kept constant, the boiler being filled with water. As steam is required it is taken from the storage tanks and the water thus consequently falls in temperature; from the storage tanks the cooled water, together with the feed, is constantly sent back to the boiler, the steam being taken from the storage tanks through a reducing valve. In order to show how his system would operate in practice, Mr. Halpin takes the case of the Kensington (London) electric light station. The total area of the load line is 15,600 effective horse power hour. The station could be worked, therefore, by engines and boilers working at 650 h. p. Under present conditions, without storage, engines working to over 2,000 h. p. were required during the short period of maximum load. In place of boilers with a capacity of 2,000 h. p. worked on an average at only one-third their capacity, Mr. Halpin would put in boilers to supply a mean demand of 650 h. p., and work them continuously during 24 hours, thus avoiding all the waste due to intermittent working. In estimating the cost of his system for the case under discussion Mr. Halpin states that working the station *without* storage tanks 10 boilers are required at a cost of £10,300, whereas he calculates that with his storage tanks three boilers and 24 tanks would be required which together would cost £15,000. Although the latter figure is £5,000 in excess of the former, Prof. Unwin points out that if in consequence of continuous working only one-half pound of coal per horse power per hour was saved, then the coal saved would be 1,270 tons, the value of which was very good interest on the extra £5,000 spent on the plant.

Without going into the difficulties which Prof. Unwin pointed out might arise when this system is applied on a large scale, but which could probably be overcome after some practical experience with it, there are other considerations which ought to be taken into account in a comprehensive survey of the system. Mr. Halpin, it will be noted, bases his calculations largely on the saving at the boiler. Now, while this may be justified to some extent the fact remains that probably, after all, the largest part of the loss in central stations occurs in the cylinders of the engines, and this, of course, the proposed system does not take into consideration. We think it would be difficult to prove that the intermittently-worked boiler is anywhere nearly so wasteful of heat as the underloaded engine, and as this is the almost normal condition of central station working, the system proposed by Mr. Halpin touches only a secondary part of the evil which it is desired to overcome.

It is at this very point that the storage battery comes in as a saving factor by permitting the engines to work at full load continuously; and in doing so it also keeps the boilers at their full activity. Without wishing in any way to detract from the ingenuity of Mr. Halpin's system, we must reserve favorable judgment until more substantial demonstrations are submitted.

THE GOEBEL DEFENCE REJECTED.

WE print elsewhere in this issue the decision of Judge Colt granting an injunction against the Beacon Vacuum Pump and Electrical Company in the suit for infringement of the Edison lamp patent. The weakest point in the defendant's case, was the insufficiency of proof as to the actual existence or use of the particular lamp designated as "No. 4" at a date prior to the date of Edison's invention. From the language of the opinion, it seems pretty clear that if it had been possible to establish beyond peradventure, the truth of the assertions made by Goebel and his son, as to this exhibit, it might in itself have been quite sufficient to overthrow the patent. It is possible, though not probable, that the missing link in the evidence may yet be found, and the truth of the defendant's contention thereby established; but unless some such event should occur, there would seem to be no probability that the decision of Judge Colt will be set aside. We are assured that the defendants will continue their fight, which, they say, is only just begun.

Telephone Litigation.

THE Government suit for the repeal of the Berliner telephone transmitter patent promises to be scarcely less interesting in electrical circles than the incandescent lamp litigation now in progress. In other columns we give some further information as to the nature of the allegations made in the bill of the Department of Justice.

Western Union.

IF there be any virtue in long years of faithful and brilliant service, immense executive ability, an intelligent comprehension of the needs of the system, and the ready loyalty of a host of old friends and subordinates, Gen. Thomas T. Eckert is the next and third President of the Western Union Telegraph Company.

LEGAL NOTES.

INCANDESCENT LAMP LITIGATION.

AN INJUNCTION GRANTED AGAINST THE BEACON VACUUM PUMP AND ELECTRICAL CO.—THE GOEBEL CLAIMS REJECTED.

CIRCUIT COURT OF THE UNITED STATES—DISTRICT OF MASSACHUSETTS.

In Equity.

No. 3096.
EDISON ELECTRIC LIGHT COMPANY,
vs.
BEACON VACUUM PUMP AND ELECTRICAL COMPANY, *et al.*

OPINION OF THE COURT.

[FEB. 18, 1893.]

COLT, *J.* In May, 1885, the plaintiff brought suit in the United States Circuit Court for the Southern District of New York against the United States Electric Lighting Company for infringement of the patent now in controversy, which was granted to Thomas A. Edison, January, 27, 1880, for an improvement in electric lamps; and on July 23, 1891, a decree was entered, adjudging the validity of the patent and ordering an injunction and account. Upon appeal to the Circuit Court of Appeals for the Second Circuit, the decree was affirmed in October, 1892. Another suit was then brought in the same court against the Sawyer-Man Electric Company, and a preliminary injunction was granted *pro forma* until a decision could be had by the Circuit Court of Appeals, which on December 19, 1892, affirmed the order, and directed an injunction. Suits were then immediately brought against the Westinghouse Electric Company in Pennsylvania, The Perkins Electric Lamp Company, and the Mather Electric Company in Connecticut, and preliminary injunctions obtained.

The present bill was filed January 10, 1893, and the plaintiff now moves for a preliminary injunction against the defendants, based upon the foregoing prior adjudications. This motion is resisted on the ground of newly discovered evidence bearing on the question of novelty of the Edison invention, which was not before the Courts in the other cases. As to these other cases, it is said that there has been but one final adjudication upon the merits, which was in the suit against the United States Electric Lighting Company, that the defendants in the other prior suits were so connected with that Company, that they were in privity with it, and that therefore injunctions were granted as a matter of course.

The suit against the United States Company was thoroughly and obstinately contested, as is shown by the record, which covers about six thousand printed pages. The general rule is that where the validity of a patent has been sustained by prior adjudication, and especially after a long, arduous and expensive litigation, the only question open on motion for a preliminary injunction in a subsequent suit against another defendant, is the question of infringement, the consideration of other defences being postponed until final hearing. *Brush Electric Company* v. *Accumulator Company*, 50 Fed. Rep. 833; *Robertson* v. *Hill*, 6 Fisher, 465, *Cary* v. *Domestic Company*. 27 Fed. Rep. 299; *Coburn* v. *Clark*, 15 Fed. Rep. 804; *Mallory Manufacturing Company* v. *Hickok*, 20 Fed. Rep. 116; *Green* v. *French*, 4 Ban & Ard. 169; *Blanchard* v. *Reeves*, 1 Fisher, 103; *Goodyear* v. *Rust*, 6 Blatch. 229; *Cary* v. *Lovell Manufacturing Company*, 24 Fed. Rep. 141: *Sargent Manufacturing Company* v. *Woodruff*, 5 Bis. 444; *Kirby Bung Manufacturing Company* v. *White*, 1 McCrary, 155; *Putnam* v. *Keystone Bottle Stopper Company*, 38 Fed. Rep. 234; *Consolidated Bunging Apparatus Company* v. *Peter Schoenhofen Brewing Conpany*, 28 Fed. Rep. 428; *Newall* v. *Wilson*, 2 De Gex, M. & G. 282; *Davenport* v. *Jepson*, 4 *De* Gex, F. & J. 440; *Boville* v. *Goodier*, 35 Beav. 427.

The only exception to this general rule seems to be where the new evidence is of such a conclusive character, that if it had been introduced in the former case, it probably would have led to a different conclusion. The burden is on the defendant to establish this, and every reasonable doubt must be resolved against him; *Ladd* v. *Cameron*, 25 Fed. Rep. 37; *Cantrell* v. *Wallick*, 117 U. S. 689; *Winans* v. *Eaton*, 1 Fisher, 181; *Bailey Wringing Machine Company* v. *Adams*, 3 Ban & Ard. 96; *Norton Door Check & Spring Company* v. *Hall*, 36 Fed. Rep. 691; *Lockwood* v. *Faber*, 27 Fed. Rep. 63; *Glaenzer* v. *Wiederer*, 33 Fed. Rep. 503; *Cary* v. *Domestic Spring Bed Company*, 26 Fed. Rep. 38.

There is no denial of infringement in the present case under the construction given to the patent in prior adjudications. The contention of the defendants is, that this motion should be denied on the ground that they have recently discovered that Henry Goebel, a German watchmaker, living in New York, invented the Edison incandescent lamp as early as 1854, and that, therefore, the Edison patent is void for want of novelty, or, at least, must be limited to the coiled form of filament. This is the same line of attack upon the patent which was unsuccessfully made in the case against the United States Electric Company. It was there urged that the Starr lamp of 1845, the Roberts lamp of 1852, the Lodyguine, Konn, and other lamps which appeared between 1872 and 1876, the Bouliguine lamp of 1877, the Sawyer and Man lamp of 1878, and the Edison platinum lamp of 1879 limited the Edison patent to narrow inventions or rendered it void for want of patentable novelty. But the Court, with a most exhaustive review of the prior art before it, refused to take this view and held that the second claim of the patent, read with the specification, covered a broad and fundamental invention, namely, an incandescent lamp, composed of a carbon filament hermetically sealed in an all glass chamber exhausted to a practically perfect vacuum, and having leading-in wires of platinum. Judge Wallace, in his opinion in the Circuit Court, says: Read by those having this knowlege, the radically new discovery disclosed by the specification is that a carbon as attenuated before carbonization as a linen or cotton thread, or a wire seven one thousandths of an inch in diameter, and still more attenuated after carbonization, can be made which will have extremely high resistance and be absolutely stable when maintained in a practically perfect vacuum. It informs them of everything necessary to utilize this discovery and to incorporate it into a practical lamp. It describes, with the assistance of the recital in the second claim, as the vacuum in which the burner is to be maintained, a bulb made wholly of glass, exhausted of air, sealed at all points by the fusion of the glass, and in which platinum leading wires are sealed by the fusion of the glass. It describes the materials of which the burner is to be made and instructs them that the materials are to be shaped into their ultimate form before carbonization. It describes the use of platinum for the leading wires, and a method of securing the leading wires and filaments, intended to dispense with clamping, which consists in moulding tar putty about the joints, and carbonizing the whole in a closed chamber.

By this invention Edison disclosed to the world for the first time a practical, commercial incandescent lamp, adapted for domestic uses. The problem was by no means easy of solution.

To subdivide the electric light and embody it in a cheap and durable domestic lamp, capable of successfully competing with gas, had for years baffled the science and skill of the most eminent electricians in this country and in Europe. The difficulty lay in the practical construction of a durable incandescent lamp rather than in a knowledge of the elements which should compose such a structure. Carbon burners, platinum wires, exhausted glass receivers were old and well-known. As early as 1845, Starr suggested in the King patent a lamp composed of a thin pencil of carbon enclosed in a Torricellian vacuum, and Roberts, in 1852, proposed to cement the neck of the glass globe into a metallic cup and to provide it with a tube for exhaustion by means of a hand pump. Later, Lodyguine and others provided their lamps with several short carbon pencils which were successively brought into circuit as the pencils were consumed, also various devices for perfecting the joints between the metal base and the glass globe, while Sawyer and Man, in 1878, made the bottom plate of glass instead of metal, and charged the lamp with an atmosphere of nitrogen gas to avoid destruction of the burner from oxidation. In his 1879 lamp Edison used a platinum burner which proved a failure because the platinum melted near the point of incandescence. Mr. Schwendler, a noted English electrician, said in 1879, "unless we shall be fortunate enough to discover a conductor of electricity with a much higher melting point than platinum, and which at the same time does not combine at high temperature with oxygen, we can scarcely expect that the principle of incandescence will be made use of for practical illumination."

The arc lamp was known as early as 1844, but its great light made it unfit for use in dwellings. The question was how to divide the electric light for domestic purposes. Many scientists considered the problem as hardly within the range of possibility. From the results of the experiments of Fontaine, the French scientist, published in 1877, it would seem that almost insurmountable obstacles, founded on the operation of natural laws, stood in the way of the successful division of the electric light. Mr. Preece, the electrician for the British General Post Office, pronounced early in 1879 that "the division of the electric light is an absolute *ignis fatuus*."

Those who dissented from this view were Mr. Edison in this country and Mr. Lane-Fox in England, who both reached the conclusion that the sub-division of the electric light could be accomplished provided the radiating surface of the burner of the lamp was reduced in extent so that only a moderate volume of light would be emitted, while at the same time the resistance of the burner was increased so as to enable the employment of relatively small conductors for leading the electric current to the lamps; or, shortly stated, the burner should have a high ratio of resistance to radiating surface. Edison first embodied this discovery in his platinum lamp in 1879, but this lamp was unsatisfactory and the problem remained unsolved. While experimenting with the platinum lamp, Edison discovered that the passage of a current through the platinum during the process of exhausting the enclosing chamber would drive out occluded gases, and thereby raise the melting point of the burner. This led him to secure greater perfection in the vacuum by the employment of a highly exhausted glass chamber similar to those used by Crookes, made entirely of glass, and with all the joints closed by the fusion of the glass. After the failure of the platinum lamp, it occurred to Edison to substitute a short filament of carbon in place of the long platinum burner, into the nearly perfect vacuum chamber, and it was found that such filament was stable at high temperature and free from disintegration and oxidation. It was thus made known that the disintegration of the carbon burner was not caused by the electric current, but was due to "air washing," or the attrition produced by the passage of the air over the highly-heated surface of the carbon.

As late as 1878, Mr. Sawyer, in a patent to Sawyer and Man, stated that no incandescent lamp had yet been devised which was practically operative, because of the defective methods employed for charging the lamp with artificial atmosphere which resulted in the disintegration of the carbon; second, because it was impossible under varying degrees of heat and pressure to maintain perfect joints; third, because unequal expansion of the carbon and its holder had resulted in fractures of the burner. But Edison overcame these obstacles, and produced a practical lamp. When we review the literature which preceded this invention, the subtle force with which it had to deal, whose laws had to be intelligently investigated and understood, the well-nigh perfect workmanship necessary in construction, and the slow steps by which the end was finally reached, it seems on its face almost incredible that the incandescent lamp of Edison was in fact invented and operated by Henry Goebel in New York forty years ago, and publicly exhibited before hundreds of people.

Goebel's story runs thus: He came to this country from Germany in 1848. He was a watchmaker and optician by trade, and opened a shop on Monroe street in New York. While in Germany he received instruction in physics from Professor Munchhausen of Hanover, and assisted him in making experiments, such as obtaining light from electricity, and making galvanic batteries. Through this means he learned to make the arc lamp, and he believed that an incandescent lamp could be produced by a small continuous carbon enclosed in an exhausted glass tube hermetically sealed. He also became familiar with the use of the common air pump, the blow pipe, the method of producing the Torricellian vacuum, and the making of carbon conductors. He says he learned at this time that the co-efficient of the expansion of glass and platinum were the same. As soon as he obtained money enough from his regular business, he began experimenting with electricity in his shop in New York. Soon after his arrival he exhibited an arc lamp on the top of his house, which called out the fire engines and caused his arrest. He then turned his attention to incandescent lamps, and made a number of them. The first form of lamp he constructed was called a "fiddle-bow" or "meat-saw", and it consisted of an exhausted tube made of glass, in one piece, with leading-in wires sealed into the enclosing chamber by fusion of the glass. The wires with the carbon burner attached resembled in form a fiddle-bow.

The next style of lamp was called the "hairpin", from the shape of the carbon burner.

A third form of lamp was also made about this time, presenting the carbon and connecting wires in a straight line, but this proved unsatisfactory as the burner broke with the heat. The leading wires were sometimes made of platinum, but generally of iron or copper, which was less expensive. The carbons used were less than one-one hundreth of an inch in diameter, and were made from flax, reed, and black cane. The first lamps were exhausted by the common air-pump, but not getting a good vacuum they were subsequently exhausted by filling the tubes with mercury, inverting them, and allowing the mercury to run out, and then sealing them off. Before sealing, the incandescent conductor was heated slightly, which, together with a little shaking, made the mercury that stuck to the carbon fall off. The ends of the leading wires were flattened, then twisted into a spiral tube, into which the ends of the carbons were inserted, and the tubes were then compressed. The joints were generally cemented with heated stove polish, though sometimes the ends of the carbon were electro-plated with copper, and an amalgam of gold and mercury applied to the joints which adhered to the copper, and sometimes a platinum sponge was used for this purpose. The electric current was produced by chemical action from batteries. The first lamps were made from cologne bottles, but afterwards from glass tubes.

A large number of the fiddle-bow and hair-pin lamps were made while living on Monroe street, between 1850 and 1872, and there was no six months up to the year 1880 when a number was not made, and prior to 1879 more than a hundred were constructed. No secret was made of any part of their construction, and they were lighted and shown to whomever desired to see them, and there was no time until after 1880 when several of the lamps were not in his possession.

If the carbons did not burn up as soon as the current was turned on, the life of the lamp was almost indefinite, but it could not be run very long at a time because the battery would give out. These lamps were used upon a wagon carrying a telescope, which was taken to Union Square and Cooper Institute for exhibition. For looking through the telescope a small fee was charged, and the lamps were used partly for light and partly to attract attention. Many hundreds of people saw these lamps while so exhibited. Another lamp was arranged to illuminate the face of a clock which hung in his bed room, and this use was continued in his Grand street house.

After removing to 468 Grand street, which was in 1877, he made a mercury vacuum pump, the idea having been suggested by hearing of the Geissler pump. In using the old process to exhaust the lamps, particles of mercury adhered to the interior parts, and it was with considerable difficulty that these particles were got out. A patent was obtained on this pump January 24, 1882. In 1881, he was employed by the American Electric Light Company. He refused to leave his shop, but his son Adolph, now dead, worked for the Company at its factory. About this time Mr. Crosby, who was connected with the Company, called upon him several times and was much interested in his lamps, and engaged him to make carbons and exhaust lamps. Until he worked for the Company he never heard of Edison, or his incandescent lamp, or of a dynamo machine for electric lighting, and had never read anything on the subject in the public prints. He does not read English, but speaks and understands it fairly well.

The Goebel lamp, Exhibits 1, 2 and 3, he recognizes as his own manufacture, and says that these very lamps were made before gas was put into his house in Monroe street. These lamps are of the fiddle-bow form. He is positive they were made before gas was introduced into his house, because they are discolored by smoke from an oil lamp flame employed in the use of the blow pipe.

After arguments on the motion, Goebel filed a supplemental affidavit and produced another lamp known as Exhibit 4. This lamp has leading-in wires of platinum, and is of much superior workmanship and finish. He also produced several tools for making carbons, and describes their use. He declares that before 1872 he had arrived at a definite conclusion as to the best material for making carbons and had settled upon bamboo. He had also decided upon platinum as the best leading-in wire, and stove polish as the best material for cementing the joints. He says that lamp No. 4 has been in his possession since before moving from Monroe street in 1872, that he made it and burned it a good many times before and since, that he made other lamps both in Monroe and Grand streets with carbonized bamboo burner, platinum leading wire connections, and glass tube, similar to No. 4, but he doubts if in any other lamps the glass feature was as handsome as in this exhibit. He has recently been informed that Mr. Pope had given as a reason why he did not think this lamp was made by the Torricellian vacuum, that there would in such case be a deposit of mercury upon the surface of the copper wire which connects the carbon with the platinum wire, and that he discovered no such appearance. He told Mr. Pope he was mistaken, provided that distilled mercury was used in producing the vacuum. The mercury that he used in producing the vacuum in these lamps was carefully distilled, sometimes three or four times, before it was used, and the process was always performed in a dry atmosphere, and other safeguards used, such as heating the mercury slightly. He had also employed, previous to 1872, a mercury pump in which no mercury was present in the glass part of the lamp, but he succeeded better with the Torricellian process than with this early mercury pump As compared with the incandescent lamps of to-day these early lamps gave a fairly good light. He declares he has received no money for his affidavits, and has no interest in this suit, and that he has given his evidence reluctantly, and after considerable urging.

I have given the substance of the leading points of Goebel's affidavits because this case rests largely upon them. With respect to the age and history of lamp No. 4, it may be said that the evidence rests entirely upon his affidavits and that of his son, Henry Goebel, Jr.

The defendants produce some forty affidavits in confirmation of the statement of Goebel respecting his lamp. Of these witnesses, five are his children, one his niece, and the remainder nearly all friends or acquaintances. So far as appears, these people are respectable and truthful. They testify generally to seeing the Goebel electric lamp in his shop and on his wagon containing the telescope, at various times between 1850 and 1882, the time and the circumstances in many instances being given in detail, and some twenty witnesses identify the early fiddle-bow lamps as the same as those which they saw. Several witnesses also observed the lamp connected with the clock. To some, Goebel explained how the lamps were made, and several assisted him in their construction. Some declare the light was good, but do not state the length of time the light would burn. Generally speaking, the testimony is confined to the old fiddle-bow lamp, and relates to a period prior to or about 1860. A number of witnesses testify as to the good character, honesty, and truthfulness of Henry Goebel.

It appears from the affidavit of Mr. Bull, an attorney at law that Henry Goebel, Jr., delivered lamp No. 1 to him at his office in New York, October 18, and lamp No. 2, November 28, 1892, and that when received both the carbons were detached from the leading-in wires, and that he was then informed by Goebel that both the carbons were intact when he put the lamps in his pocket to bring them to his office. Henry Goebel, Jr., states that he delivered lamp No. 3 to Mr. Bull at the same time with No. 2, and that he broke the carbons in lamps 1 and 2 on the way to Mr. Bull's office.

From Mr. Williams' affidavit, it seems that gas was introduced in Monroe Street in or about the year 1854; this, with the testimony of the elder Goebel and other witnesses, fixes the date of the construction of lamps 1, 2 and 3, as early as 1854.

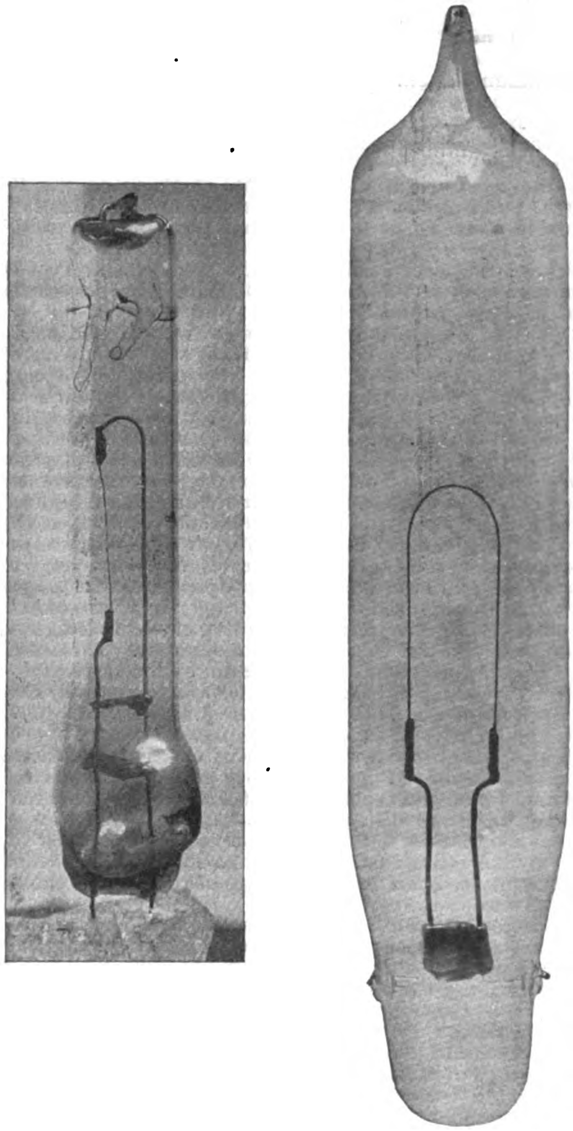
Mr. Curtis, the counsel for the defendants in the New York cases, states that he first heard of Henry Goebel in the early part of 1882, and that in answer to his questions, he said that he had made incandescent lamps like Edison's as early as about 1850. Owing to Goebel's imperfect English he had difficulty in understanding him. He gathered from the conversation that Goebel had not made any use of his lamps except for laboratory experiments, and that his work was not continued for more than a year or two after 1850. He asked him to produce some lamps, and he said he would look them up. His recollection is that he saw Goebel again, but that he had no further information to impart.

In the latter part of 1890, Mr. Bull, who had been counsel for the Consolidated Electric Company, informed him that Goebel's sons corroborated their father's statement and that further additional evidence could be procured, but after consultation with Gen. Duncan they concluded that the evidence was not sufficient to warrant an application to reopen their case to admit it. At the time of the injunction motion in the Sawyer-Man case in November, 1892, he made further inquiry in regard to Goebel, and was informed that some additional evidence had been obtained. Upon consultation with his associates, Mr. Wetmore and Mr. Root, it was concluded that the matter had not been sufficiently developed to present it as a defence in that case. Mr. Curtis goes on to state that, had he known of anything like the character and extent of the Goebel evidence as presented in this case, he should have regarded it of the greatest importance as constituting one of the best defences in their cases.

In further support of the Goebel anticipation, several experts give affidavits to the effect that the Goebel lamp, assuming that it was made prior to 1879, contains the broad invention covered by the second claim of the Edison patent, as it embodies the same combination of a carbon filament with an all-glass exhausted receiver and conductors passing through the glass.

Mr. Pope declares that Goebel lamps 1, 2 and 3 have a carbon filament within the meaning of the second claim of the Edison patent as defined by the Court, a receiver made entirely of glass and exhausted of air, and conductors passing through the glass and all these elements combined for the purpose set forth in the patent; that these structures embodied the conception that carbon would stand high temperature, even when very attenuated, if operated in a high vacuum without the phenomenon of disintegration.

He finds these particular lamps are not now in a condition to be operated, but he is satisfied that when first constructed they were capable of such operation, and had in fact been so operated. He knows of no reason why these lamps should not have been made long prior to 1879, and should not last as long and be as practically useful as many forms of lamp described by Edison in his patent. He finds the leading-in wires in lamps 1 and 2 to be of iron, and in 3 of copper. In No. 3 he finds the leading-in wires are sealed by fusion into the lower end of the glass chamber, the glass being pressed around them when hot. The filament is made of carbonized woody fibre, apparently of bamboo or cane, and has a diameter approximately of eight to ten one-thousands of an inch. The glass chamber is five inches long and seven-eighths of an inch in diameter, but is now cracked near the bottom, and consequently there is no vacuum.



GOEBEL LAMPS, NOS. 1 AND 4.

Mr. Cross confirms these statements, and calls particular attention to the fact that the Goebel carbon is by reason of its small diameter a "filament" as distinguished from a "rod," according to Professor Barker's tables, and in the sense in which that term is used in the Edison patent as judicially construed.

In a second and supplementary affidavit, Mr. Pope says, with respect to the highly-finished Goebel lamp No. 4, which has platinum leading-in wires and hair-pin shaped carbon, that at first he had doubts whether it was constructed as early as Goebel, and his son Henry, said, or prior to 1872. This arose from the circumstance that the joint between the carbon and copper wire appears to have been made in part by electro-plating, and his experience led to the opinion that if the lamp had been first filled with mercury and then exhausted by inverting the tube, in one of the ways Goebel practiced, the mercury would have united with the surface of deposited copper, and some traces of it remained, but as no such traces appeared visible in this lamp, he was led to believe that it must have been exhausted upon a vacuum pump. Upon questioning Goebel however, he found that he had used chemically pure or distilled mercury. Afterwards, Mr. Pope, by experiments, discovered that chemically pure mercury did not adhere to copper, nor leave any discoverable trace. This is the reason why this lamp was not before the Court at the arguments on this motion.

Mr. Pope is unable to get a current through this lamp because the circuit is somewhere broken. He sees no reason why it might not have been made before 1872. He is of opinion that it represents an advance over the prior Goebel lamps in details of construction and general workmanship and that it is entirely capable, with the break repaired, of practical use as an incandescent lamp. He thinks it would burn without doubt three or four hundred hours, and that it clearly embodies the invention of the second claim of the Edison patent, as construed by the Court. He is also of opinion that iron leading-in wires are practicable in the construction of an incandescent lamp, and the next best thing to platinum. Mr. Cross, in a supplemental affidavit, confirms these statements. Mr. Cary, the electrician of the defendant company, states in an affidavit, that from experiments he has recently tried incandescent lamps capable of practical use can be made with iron leading-in wires.

There was filed at the same time with the foregoing supplemental affidavits, other affidavits of persons who knew Goebel and saw his lamps. The light from the Goebel lamp seems to grow brighter and more steady as the affidavits multiply. For example, Mr. Voss, in his second affidavit, says: "Some of the larger lamps were attached in the store like gas fixtures. . . . I have seen the store lighted with these electric lamps alone when the gas was turned off, and the light in the store was a nice brilliant light of, I should say, from eight to ten candle power to the lamp." Again, Mr. Hall states that the store was entirely lighted up by these lamps, which were brighter than gas jets; in fact, too bright, and that the light was very steady. Mrs. Stark says the lamps were brighter than an oil lamp or gas flame, and would burn an hour, George Pasbach, who married Goebel's niece, declares he could see to read by their light, and do fine work. Edward F. Mulligan says the lamps in the Monroe Street store gave a nice bright light, whiter and much better than gas, and that you could easily read or do work by it.

To meet this alleged Goebel anticipation, the plaintiff introduces the prior adjudications upon the Edison patent, the affidavits of Edison and Barker relating to the history of the invention and the prior state of the art, and the affidavit of Upton shows that the defendant company was incorporated in 1890, and is now an active competitor in manufacturing and selling incandescent lamps. The plaintiff also produces the affidavit of Professor Elihu Thomson to the effect that the Goebel lamps, like Exhibits 1, 2 and 3, could not have been useful for ordinary lighting purposes, and were never a practically operative light. One reason for this is, because the leading-in wires are of iron or copper, under which conditions a vacuum cannot be maintained, since the rate of expansion of iron and copper is very different from glass, the result being that the lamp begins to lose its vacuum as soon as it is heated and cooled. Another reason is that the leading-in wires are poorly and crudely sealed in, the glass work being thoroughly bad, and the lamps cracked and blackened on the ends by improper flame. While these lamps, in spite of leakage, might have been used for a short time, they could not have had a sufficient brilliancy for ordinary lighting purposes, nor possessed any commercial value. The vacuum not being maintained the heat would be carried away from the incandescent body by currents of gas, and this waste of energy robs the burner of its light-giving power. This statement, by Prof. Thomson, is agreed to and confirmed by the affidavits of John W. Howell and John E. Randall.

Prof. Thomson further says, that he remembers Henry Goebel as far back as 1881 or 1882, and that he visited his shop at that time, and that an endeavor was made to impress him with the value of the Goebel anticipation.

The plaintiff also, by permission of Court, filed affidavits after the arguments on the motion. These are important, not only as contradicting statements found in the affidavits of defendants but for other reasons.

A number of these witnesses, who were neighbors or acquaintances of Goebel, or had other means of knowledge, deny that he exhibited any electric lights in connection with his telescope or in his shop, about 1860 or the years following.

There are the affidavits of John W. Howell and Frank Holzer, electricians, who corroborate the statement of Prof. Thomson that the Goebel lamps, 1, 2 and 3, were never practically operative by reason of a defective vacuum, and never possessed any commercial value.

Several witnesses state that Goebel spoke English well, and it is also proved that articles relating to the subject of incandescent lamps and Edison's inventions were printed during 1880, in the *Staats-Zeitung*, a German daily newspaper, published in New York.

But the more important evidence has reference to those persons who saw or dealt with Goebel, and who investigated his claim to have anticipated Edison in the art of incandescent lighting.

William C. Dreyer states that he undertook to form a company to purchase from Henry Goebel his inventions and patents, and that in 1882 he did procure from him an option for three months of all his inventions relating to electric lighting upon payment to him of $500, and an extension of the option for another three months, for which an additional $425 was paid. Goebel was also to have a large compensation from the company if formed. At that time, he said he had patented or applied for patents on a mercury pump, and a spiral holder for the carbon in an incandescent lamp. He said he had made small incandescent lamps called the fiddle-bow. It was considered of great importance to have one of these lamps, and he made every effort to find one, but never succeeded. The conversations with Goebel were carried on in German. The production of an old lamp was vital in this matter. During this time, negotiations with the Edison Company were attempted through S. B. Eaton. The whole subject was gone over with E. N. Dickerson, the patent lawyer, who said that even if Goebel did what he claims, it was nothing but an abandoned experiment. The negotiations with the Edison Company were in consequence dropped.

Albert Hetschel, a manufacturer of thermometers and scientific apparatus, states that in 1881 he was in the employ of the American Electric Light Company, and was directed to work with and help Henry Goebel, and was at his shop for several months. Hetschel describes how Goebel in a crude way made three or four little incandescent lamps with the use of a poor vacuum pump; that he was unable to make a successful lamp, and he is certain that if he had possessed at that time any incandescent lamps he would have shown them.

Otto A. Moses, a mining engineer, then in the service of the Edison Company, visited Goebel in 1884. Goebel made some carbons for him. During this time, being much interested in the subject, he inquired of Goebel what he had done in the field of incandescent lamps. He examined all the lamps Goebel had and asked him to produce some of his old ones. Goebel requested permission to visit his laboratory and did so, and afterwards solicited employment for himself and his son. Under these circumstances, he says it is improbable that Goebel at that time had any old meat-saw or hair-pin lamps in his possession.

Ludwig K. Bohm, an electrical expert, who was associated with Edison in 1879, and afterwards in 1881 electrician of the American Electric Light Company, had several conversations with Goebel at the office of the company. At that time Edison's invention had been published in the English and German papers in New York. He conversed with Goebel in German on the subject of incandescent lighting, and he is certain that he would have mentioned his historical lamps if he had made them.

He then proceeds to discuss the lamps described in Goebel's affidavit, and declares that a vacuum sufficiently high to enable a filamentary carbon to last could not be made by filling the tube with mercury, and then inverting it, because there is always air in the mercury, and that air also clings to the glass walls. In making standard barometers by the Torricellian vacuum it was found necessary to boil them out for hours in specially constructed apparatus. Further, owing to the specific gravity of mercury the filamentary carbon would be broken during the operation of filling and inverting the chamber. The lamps are likewise imperfect from the use of iron or copper leading-in wires, and no one of them shows any evidence that it ever contained a good vacuum.

William McMahon in 1880 was interested in starting a company to compete with the Edison lamp, and he and his associates, George Crosby and Edwin Fox, organized the American Electric Light Company in 1881. Crosby took him and his brother to Goebel's shop to talk over electrical matters. Goebel showed him an arc lamp, but said he had never made any incandescent lamps. He remembers also seeing some carbons and a vacuum pump which appeared like a swinging pump. Goebel's son was soon after employed by the American Company. There was intense excitement at this time over the Edison incandescent lamp. Everybody recognized that Edison had made the invention. There was every reason at the time why Goebel and his son should have disclosed fully what they had done in this direction. If any one had preceded Edison in his invention, unlimited capital could have been secured for an opposition company. The American Company wanted to make the Edison lamp but did not dare to. For these reasons he is satisfied that Goebel never made an incandescent lamp prior to March, 1881. Thomas G. McMahon, his brother, confirms this story in his affidavit.

Sherburne B. Eaton, the legal adviser of the Edison Company, states that in May, 1882, the law firm of Dickerson & Dickerson called his attention to the alleged inventions of Henry Goebel. They said that he claimed to have invented an incandescent lamp resembling the Edison. Goebel's representative in this matter was William C. Dreyer. No price was made, but they were asked to look into the matter. The subject was laid before the Executive Committee of the Edison Company, and it was decided that Goebel had nothing worth buying. Mr. Dickerson's opinion was that if Goebel had made the inventions he claimed, they amounted to nothing more than an abandoned experiment. On November 28, 1882, Henry Goebel, Jr., called upon him, as representing the Edison Company, and made another offer to sell the inventions and good will of his father, naming the price of $20,000, and the matter was again submitted to the company. On December 12, 1882, he called again and was informed that the company did not wish to buy.

A patent was issued to Henry Goebel for an improvement in electric incandescent lamp, October 24, 1882. This invention has reference to securing and cementing the carbon burner into flattened and spirally coiled ends of the conducting wires. The second claim, as drawn in the original application, was rejected by reference to the Edison patent, now in suit.

Upon consideration of the whole of the evidence on this motion I have reached the following conclusion:

It is extremely improbable that Henry Goebel constructed a practical incandescent lamp in 1854. This is manifest from the history of the art for the past fifty years, the electrical laws which since that time have been discovered as applicable to the incandescent lamp, the imperfect means which then existed for obtaining a vacuum, the high degree of skill necessary in the construction of all its parts, and the crude instruments with which Goebel worked.

Whether Goebel made the fiddle-bow lamps 1, 2 and 3 it is not necessary to determine. The weight of evidence on this motion is in the direction that he made these lamps or lamps similar in general appearance, though it is manifest that few, if any, of the many witnesses who saw the Goebel lamp could form an accurate judgment of the size of the filament or burner. But assuming they were made, they do not anticipate the invention of Edison. At most they were experimental toys used to advertise his telescope, or to flash a light upon his clock, or to attract customers to his shop. They were crudely constructed, and their life was brief. They could not be used for domestic purposes. They were in no proper sense the practical commercial lamp of Edison. The literature of the art is full of better lamps, all of which were held not to anticipate the Edison patent. The prior art demonstrates that to protect a carbon filament ten one-thousandths of an inch in diameter from speedy disintegration, the lamp chamber must maintain a nearly perfect and stable vacuum, and every part of the structure must be composed of such materials and so put together as not to imperil this vital condition. Leaving out other defects, it is abundantly shown that the Goebel lamp did not possess this requirement, and could not by reason of the elements which entered into its composition and the mode in which it was constructed. Goebel says he made more than a hundred lamps, and that a continual improvement took place in their construction, and yet the only three lamps produced at the hearing by his own confession were made as early as 1854, or before gas was introduced into his house. Where are the other lamps, which show these improvements except Exhibit 4, which I will deal with presently? The evidence of Goebel and his witnesses point to the conclusion that work ceased on these lamps in the "fifties," and was not revived until Edison twenty years later startled the electric world with his invention. Goebel brought from Germany the ideas contained in the old lamp of Starr, with its carbon pencil enclosed in a Torricellian vacuum, and he probably constructed some lamps after that pattern. In doing this he was up to and in line with the art as it existed at that early day, but to say that with a sudden bound he jumped from Starr to Edison passes the limits of credulity. The history of great inventions shows a gradual and labored progress. Each new investigator records some advance until it may be the desired discovery is almost within his grasp, but it is only after many attempts and many failures that some one appears who accomplishes the long sought for result. The discovery of the domestic incandescent lamp is no exception to this rule, as the record in the New York case bears witness. Speaking from the standpoint of the art of incandescent lighting in 1854, and in 1892, are two different things, and it is, therefore, quite easy for witnesses to think that Goebel did much more than there is any legitimate reason to suppose.

As for lamp No. 4, I cannot but view it with suspicion. It presents a new appearance. The reason given for not introducing it before the hearing is unsatisfactory. This lamp, to my mind, envelopes with a cloud of distrust the whole Goebel story. It is simply impossible under the circumstances to believe that a lamp so constructed could have been made by Goebel before 1872. Nothing in the evidence warrants such a supposition, and other things show it to be untrue. This lamp has a carbon filament, platinum leading-in wires, a good vacuum, and is well sealed and highly finished. It is said that this lamp shows no traces of mercury in the bulb because the mercury was distilled, but Goebel says nothing about distilled mercury in his first affidavit, and twice he speaks of the particles of mercury clinging to the inside of the chamber, and that for this reason he constructed a Geissler pump after he moved to 468 Grand street, which was in 1877. Again, if this lamp has been in his possession since before 1872, as he and his son swear, why was it not shown to Mr. Crosby, of the American Company, when he visited his shop in 1881, and was much interested in his lamps? Why was it not shown to Mr. Curtis the leading counsel for defendants in the New York cases, when he was asked to produce a lamp and promised to do so? Why did not his son take this lamp to Mr. Bull's office in 1892, when he took the old fiddle-bow lamps 1, 2 and 3? Why did not his son take this lamp to Mr. Eaton's office in 1882, when he tried to negotiate the sale of his father's inventions to the Edison Company? A lamp so constructed and made before 1872 was worth a large sum of money to those interested in defeating the Edison patent like the American Company, and Goebel was not a rich man. Both he and one of his sons were employed in 1881 by the American Company. Why did he not show this lamp to McMahon when he called in the interests of the American Company and talked over electrical matters? When Mr. Dreyer tried to organize a company in 1882, and procured an option from him of all his inventions relating to electric lighting, for which $925 was paid and when an old lamp of this kind was of vital consequence and would have insured a fortune, why was it not forthcoming? Mr. Dreyer asked Goebel to produce an old lamp and was especially anxious to find one pending his negotiations with the Edison Company for the sale of Goebel's inventions. Why did he not produce this lamp in his interviews with Bohm of the American Company, or Moses of the Edison Company, when it was for his interest so to do? The value of such an anticipation of the Edison lamp was made known to him. He was desirous of realizing upon his inventions. He was proud of his incandescent lamps, and was pleased to talk about them with anybody who would listen. Is it conceivable, under all these circumstances, that he should have had this all-important lamp in his possession from 1872 to 1893, and yet no one have heard of it or seen it except his son? It cannot be said that ignorance of the English language offers an excuse. He knew English very well, although Bohm conversed with him in German. His children spoke English. Neither his ignorance nor his simplicity prevented him from taking out three patents, the first in 1865 for a hemmer, and the last in 1882 for an improvement in incandescent lamps. If he made lamp No. 4 previous to 1872, why was it not also patented?

There are other circumstances which throw doubt on this alleged Goebel anticipation. The suit against the United States Electric Lighting Company was brought in the Southern District of New York, in 1885. Large interests were at stake, and the main defence to the Edison patent was based upon prior inventions. This Goebel claim was then investigated by the leading counsel for the defence, Mr. Curtis. It was further inquired into in 1892, in the case against the Sawyer Man Company. It was brought to the attention and considered by the Edison Company in 1882. It was at that time known to the American Company who hoped by this means to defeat the monopoly under the Edison patent. Dreyer tried to organize a company for its purchase. Young Goebel tried to sell it. It must have been known to hundreds of people. And now when the Edison Company after years of litigation, leaving but a short time for the patent to run, have obtained a final adjudication establishing its validity, this claim is again resurrected to defeat the operation of the judgment so obtained. A Court of Equity should not look with favor on such a defence. Upon the evidence here presented, I agree with the first impressions of Mr. Curtis, and with the opinion of Mr. Dickerson that whatever Goebel did must be considered as an abandoned experiment.

It has often been laid down that a meritorious invention is not to be defeated by something which rests in speculation or experiment, or which is rudimentary or incomplete. The law requires not conjecture, but certainty. It is easy after an important invention has gone into public use for persons to come forward with claims that they invented the same thing years before, and to endeavor to establish this by the recollection of witnesses as to events long past. Such evidence is to be received with great caution, and the presumption of novelty arising from the grant of the patent is not to be overcome except upon the most clear and convincing proof. *Coffin* v. *Ogden*, 18 Wall, 120; *Brush* v. *Condit*, 132 U. S. 89; *The Telephone Cases*, 126 U. S.; *American Bell Telephone Company* v. *People's Telephone Company*, 22 Fed. Rep. 809; *Motte* v. *Bennett*, 2 Fisher, 642; *Parham* v. *American Buttonhole Company*, 4 Fisher, 468; *La Baw* v. *Hawkins*, 1 Ban. & Ard. 428; *Gottfried* v. *Philip Best Brewing Company*, 5 Ban. & Ard. 4; *Worswick Manufacturing Company* v. *City of Buffalo*, 26 Fed. Rep. 128.

When the defendant company entered upon the manufacture of incandescent lamps in May, 1891, it well knew the consequences which must follow a favorable decision for the Edison Company in the New York case.

Owing to the large interests involved, I have carefully considered this motion, and I am satisfied upon the evidence, and the law applicable thereto, that it should be granted.

Injunction granted.

GOVERNMENT SUIT TO ANNUL THE BERLINER TELEPHONE PATENT.—I.

In The Electrical Engineer of February 15 brief mention was made of the suit brought by Attorney-General Miller against the American Bell Telephone Company and Emile Berliner, in the Circuit Court of the United States, District of Massachusetts, for the annulment of the Berliner patent of November 17, 1891, No. 463,569. This patent covers broadly the "Contact" or microphone form of speaking telephone transmitter; the only variety of transmitter hitherto successfully employed commercially. It has undoubtedly been the expectation or hope of the American Bell Telephone Company that through its possession of this patent it would be able to extend its patent monopoly of practical telephony for many years after the expiration of the fundamental Bell patent in March next. The Blake transmitter patents have expired because of the termination of prior foreign patents, as is generally known; and, according to Circuit Court decisions in similar cases, the Edison telephone patents issued last year are now void for the same reason. Thus the Berliner patent, far more sweeping and comprehensive in scope than any other transmitter patent, would seem to be the main reliance of the Bell company for the maintenance of its control of practicable forms of telephones when Bell's patents shall have expired.

The validity of the Berliner patent has been questioned by many persons familiar with patent law, on various grounds; and, in view of the public interest involved it is obviously a general advantage that the Department of Justice has brought suit to determine its status, and it will be a further benefit if the case can be pressed to a speedy issue.

The allegations of the Government bill are many and various. One of the most significant is, that, in Berliner's application, filed June 4, 1877, he described a telephone transmitter which depended upon the *make-and-break* of contact between the electrodes, and that *no other kind* of transmitter was described in the application; while in the patent as issued, the *make-and-break* transmitter had been eliminated and another substituted which depended for its operation upon *constant contact* between the electrodes; and that the amendments and substitutions were made after Berliner had assigned his invention to the Bell company. The bill further shows that after Berliner's assignment he filed applications and received six patents during the years 1879–1881 for telephones operating upon the constant contact principle, in every one of which there is present the same broad feature that is an element in the broad claims of the patent of 1891 issued upon his application of June, 1877; and the bill avers that it is against justice and equity and contrary to the plain spirit and intent of the patent laws that the monopoly of one and the same invention shall be prolonged in one and the same person by the grant, first, of a patent or patents for the invention in practical or applied form, and afterward of a patent covering nakedly and broadly the fundamental principle of the same invention. It is then pointed out that from the time of acquiring ownership of Berliner's invention the Bell company, up to the issue of the patent in question (November, 1891), not only had control of Berliner's application of June, 1877, but owned the inventions and patents of Blake, Berliner, and others, under which it was enjoying a monopoly of the use of the broad invention of the constant contact telephone transmitter, and that therefore the Bell company was in duty bound to speed the progress of Berliner's application by every legal means; and that if by any act, or failure to act, on its part, the issue of the patent was unduly delayed, such delay ought to and does invalidate it. The complaint alleges that the Bell company, so far from performing its duty in this regard, did intentionally prolong and delay the pendency of the application of Berliner more than thirteen years, for the purpose of prolonging its monopoly.

Much stress is laid upon the amendments of Berliner's application and the substitutions of new drawings by the attorneys of the Bell company. "This amended specification," the complaint says, "was drawn with consummate art and with intent, as your orator believes and charges, to mislead and deceive the Examiner of the Patent Office by concealing from him that the amendment introduced into the application a new and substantial invention not found in the original application." At length Berliner filed an affidavit in which he said that the matter described in the substitute was invented by him prior to filing the original, and formed part of his original invention."

ELECTRIC RAILWAY DEPARTMENT.

LONG ELECTRIC RAILROADS IN OHIO.[1]

Unless present projects greatly miscarry, the building of electric railways through the country districts and between small cities in northern Ohio will be carried on a much more extensive scale the coming summer than ever before. It is being more generally recognized on all sides that electricity is the best motive power for local travel where the patronage is limited, and plans for the development of traffic between small centres of population and in suburban districts by means of it are proposed on every hand. The construction of electric lines between small cities has already been rather notable in extent in the northern districts of Ohio, and the investments have proven so satisfactory that it is comparatively easy to secure capital for new lines. This city is noteworthy for its electric street railways, and the prosperity of these enterprises has been influential also in stimulating the building of country electric roads.

The most conspicuous projects fully decided upon is the line from East Cleveland to Willoughby, the pretty little lake-shore village 18 miles east of this city. The Lake Shore and Michigan Southern and the Nickel-Plate Roads both touch Willoughby, so that its communication with this city is already good; but the East Cleveland Electric Railroad Company, which has covered the choicest residence districts of this city with its lines, and for several years has operated a suburban line out Euclid road three miles to Collamer, will build through to Willoughby in the spring. It extended its road four miles beyond Collamer last summer and will construct the remainder as soon as possible. The line when complete will lie through many of the finest vineyards in Ohio and open up a very desirable suburban residence district. It has already done much to enhance real-estate values, though its projectors had no such end particularly in view, and fairly conservative gentlemen near Willoughby confidently expect property along the new line there to double in value within a year after it is in operation. It is likely the line will be used to market grapes and produce from truck farms to some extent, but it would undoubtedly prove a good investment if it had nothing but strictly passenger traffic to depend upon.

The most extensive system yet proposed has not taken positive form, but the nucleus for it exists, as in the case named above, and there is good reason to expect that considerable extension will occur this summer, even if all that is now proposed fails of accomplishment. A year ago a road was built between the thriving manufacturing cities of Canton and Massillon, nine miles in length, and is operated very successfully, cars running every hour or oftener during the day. Between Warren and Niles also, and in Youngstown and Alliance, electric roads have been in operation for months. Now it is proposed to connect Akron with Canton, 23 miles away, Canton with Alliance, 18 miles distant, and Alliance with Niles by a road less than 25 miles long. If this is carried out, all the thriving industrial centres in northern Ohio outside this city will be connected by electric lines.

From Akron a line will be constructed in early summer to Cuyahoga Falls and Silver Lake, four miles away, and will unquestionably prove profitable, though two railroads now connect the falls with Akron, and the pretty picnic resort at Silver Lake is not far away. The right of way is now being secured from the falls also to Ravenna, fifteen miles distant, taking in the thriving little city of Kent by the way, and two syndicates are competing to secure the franchise from the Portage County Commissioners. If a map is consulted, it will be seen that these projects, in every case, will connect towns between which direct railway communication now exists, and electricity will thus compete with steam in a sense. It is already doing this successfully in a number of cases; the Canton and Massillon and the line between New Brighton, Pa., and Beaver Falls, which was built by Mr. W. W. Hazard of this city, are notable recent instances The first electric road connecting two towns in Ohio, that between Canal Dover and New Philadelphia, in Tuscarawas County, which has now been in operation two years and a half, had to compete directly with a steam railway and has been profitable from the beginning. The greater frequency of the cars and lower fare are the principal reasons for success. Neighborhood communication increases greatly with facilities, and a train every hour, with fare about one-half that on steam roads, more than doubles the travel between country towns. Where there are no heavy grades necessitating cuts, an electric road can be built and equipped with power for $5,000 to $8,000 per mile, and in few cases does the cost exceed $10,000. For a line three miles long four employees are sufficient to man the power-house and run a car every hour, and the expense for repair of roadbed, wires, etc., is very small. A comparatively small revenue, therefore, pays a fair return on the investment.

The most expensive electric road yet built in Ohio, and perhaps in the country, is that between Wellsville and East Liverpool. It is five miles long and connects two thriving manufacturing towns which hitherto have never had direct rail communication, because of the very broken, hilly character of the country between them. Cuts thirty feet deep had to be made in its construction, and in some places a twenty-foot roadway was cut through fifteen and twenty feet of solid rock. The entire cost, including rolling stock, has been placed at $300,000, but that is doubtless a high figure. It was built by Cleveland capital and has been profitably operated for over a year, to the great advantage of both towns. Farther south at Wheeling, W. Va., another Cleveland syndicate controls lines connecting Wheeling with Bellaire, Martin's Ferry, and Benwood, having about eight miles of track outside the municipal limits.

---

[1] *Special Correspondence from Cleveland* in the *Evening Post*, New York, Feb. 15, 1893.

In northwestern Ohio another large project is being agitated. The Tiffin and Fostoria Electric Railway Company has already been incorporated, with $175,000 capital stock, to build a road 18 miles long between the two thriving towns in question. Hon. Charles Foster, ex-Congressman George E. Seney, and other less prominent capitalists are back of it. The country through which the line is to be built is comparatively level, and it is proposed at several of the more picturesque spots to secure and improve land for parks and picnic grounds. The investment of the company will depend, of course, very much upon the amount of land purchased for such purposes, but it cannot be questioned that the capitalization is greatly in excess of the actual cost of constructing the road itself. This road will be one link in a system for which subscriptions and right of way are now being secured, which, as projected, will be nearly 100 miles in length. It begins at Ottawa city on the northernmost point of Catawba Island, which is in reality a peninsula and part of one of the greatest fruit-growing districts in the Central West, and runs thence to Port Clinton, whence it is to be extended to Fremont, Fostoria, and Findlay, and touch many villages en route. As there are few hills to be encountered, the cost of construction would be small and the road would be very convenient in marketing the grapes and peaches in their season. The Port Clinton and Ottawa City Line is expected to be in operation by the 1st of August. In the same section of the state another line will be constructed the coming summer, connecting Sandusky with Milan, Huron, and Norwalk. Besides these the building of a considerable number of suburban lines, extensions, and small city roads is under discussion.

This great development of electric roads has led to some legislation already and promises to be followed by more. Last winter Martin Dodge of this county, who is a great enthusiast on the subject, introduced and secured the passage of a measure that enables electric railroad companies to bring condemnation proceedings against any turnpike or plank-road company to obtain the right to occupy part of the roadway when the two companies cannot agree to terms and conditions without appealing to the courts. It is local in scope, applying only to this county; and was the first legislation of its kind in the country. It is part of a plan to build a system of electric roads from Corlett Station to Chagrin Falls, and from Chardon, Geauga County to the Falls, which will probably take tangible form this summer, a suburban road being extended three miles beyond the southeastern limits of the city to connect with the projected system at Corlett Station. A number of prominent local real estate men are interested in the scheme, which contemplates carrying freight as well as passengers. 23 miles of road would be included in the system, and notwithstanding the hills encountered toward the eastern end of the line, its estimated cost is but $100,000. This, however, does not include power station and rolling stock.

The electric roads thus far have a peculiar status in Ohio. The Railroad Commissioner has recently called attention to the fact and urged action. The Canton and Massillon, and Granville and Newark roads, for example, carry both freight and passengers, have contracts for carrying the United States mails, and are common carriers for an express company. In a word, they differ from other railways only in motive power used. Yet they cannot be considered amenable to the railway laws of the commonwealth. For this reason, no official statistics are obtainable of their earnings, capital, etc. No data are being collected for a future use, although all such roads, being built along public highways, sometimes occupying part of the roadway, enjoy exceptional privileges and will in time call for special regulation. It is probable that a bill will be passed making the other railway laws of the state applicable both to country electric lines and street railways. This would bring them under the supervision of the State Railroad Commissioner and insure the collection of full and reliable statistics. The rapid development of the roads makes this very necessary for the future protection of the public.

A VERY LONG TROLLEY ROAD FOR PENNSYLVANIA.

THE charter granted to a trolley road, eighty miles in length, by the State Department at Harrisburg last week, has caused a feeling of alarm among steam railroad officials. The road is called the Northumberland, Bloomsburg and Scranton Street Railway Company, and connects thirty-nine towns in that region. Among them are Lackawanna, Pittston, Catawissa, Mechanicsville, and Nanticoke. It is a very busy centre, and the establishment of a trolley line will materially interfere with the local traffic of the steam roads. At the office of the Reading Railroad Company it was stated that these roads were generally given the privilege to run over the turnpikes and township roads, thus saving the expense of grading, the largest item of the steam roads' expense in a mountainous country. It was acknowledged that it would make a difference in the revenues of the companies with which such road came in competition. The capital of the new road is $500,000, and it is said that a syndicate in Philadelphia is furnishing the money.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

WE give below the Fifteenth Convention programme of the National Electric Light Association, St. Louis:—

Tuesday, February 28, 1893, Meeting of the Executive Committee at 9 a. m., parlor, Southern Hotel. Morning Session, 10.30 o'clock, Bell Telephone Building. Address of welcome, Hon. E. A. Noonan, mayor of St. Louis; address, president Jas I. Ayer; report of Committee on Data. Afternoon Session, 2 o'clock. Report of Committee on Safe Wiring; report of Committee on World's Columbian Fair; paper by A. D. Adams, "Wrought *vs.* Cast Iron for Field Magnet Frames."

Wednesday, March 1, Morning Session, 10 a. m. Paper by H. C. Myers, "Preservation of Poles and Cross Arms"; paper by Chas. S. Bradley, "Long Distance Transmission of Power"; paper by L. B. Stillwell, "Under What Conditions is the Use of Water Power Economical." Wednesday Afternoon Session, 2.30 o'clock. Paper by E. A. Armstrong, "Morals of Corporations"; paper by R. H. Sterling, "Some Experiences With the Alternating System"; paper by William Brophy, "Relation of Insurance to Electric Lighting and Power." Wednesday Evening Session, 8 o'clock. Lecture by Nikola Tesla.

Thursday, March 2, Morning Session, 10 o'clock. Paper by W. H. Browne, "Underground Conduits and Conductors"; paper by Calvert Townley, "Incandescent Lamps From a Commercial Standpoint"; paper by Dr. Louis Bell, subject to be announced. Thursday Afternoon Session, 2.30 o'clock. Paper by Prof. Geo. Forbes, of London,. Executive Session. Report of secretary and treasurer; election of officers.

THE POWER PLANT AT THE WORLD'S FAIR.[1]

THE power plant at the Columbian Exposition occupies nearly seven acres, or about one-fourth of the entire floor space of the "Palace of Mechanic Arts," popularly known as Machinery Hall. The plan is given in the supplement to this issue. The boiler-house, immediately adjoining, is 627 feet long and 86 feet wide, with an addition of the same width and 200 feet in length. About 25,000 h. p. will be generated here in water tube boilers of various makes.

The space allotted to the power plant, 100 feet wide by 1,000 long, is divided into 14 sections, separated by aisles, and the machinery is arranged within these sections in classified groups.

These 15 blocks comprise what is known as the power plant proper, including the arc lighting section, the incandescent section and the power section, and the total indicated horse power of the 40 engines employed is about 18,000 at maximum economical load.

Oil will be used for fuel. The storage reservoir is 3,200 feet from the power plant, on the shore of the lake, and consists of eight tanks having an aggregate capacity of 112,144 gallons, sufficient to develop 393,400 h. p. hours. The oil is pumped into a stand-pipe, whence it flows to the boilers. All important valves in this installation are electrically operated, and the burners under the boilers are electrically connected with the pressure gauges and are automatically regulated.

The work of planning and installing the power plant was carried out by Mr. Frederick Sargent, the chief mechanical and electrical engineer of the Exposition, ably assisted by a judiciously selected and efficient staff of associates.

ELECTRICITY AT THE WORLD'S FAIR.

THE balance sheet of the World's Fair, to date, shows the following disbursements:—Electricity building, $416,428; electric plant, $284,300; electrical engineering, $48,699; office building for mechanical and electrical departments, $8,250; police signal boxes, $8,881; machinery building, $978,496; mechanical engineering, $32,000; boiler plant, $38,494. On the receipts side is an item of $5,813, for electric power furnished.

PROF. GEORGE FORBES, F. R. S., has just arrived from England, to attend to his consultation work on the Niagara power transmission project. He has been invited to participate in the St. Louis convention, and will probably do so.

---

[1] Abstract, with Supplement Illustration, from *World's Fair Electrical Engineering.*

MISCELLANEOUS.

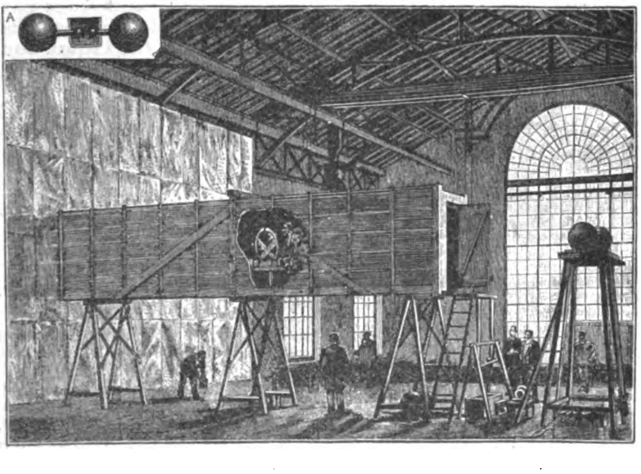
EXPERIMENTS OF MM. SARASIN AND DE LA RIVE ON ELECTRICAL OSCILLATIONS.

THE experiments first undertaken by Hertz to demonstrate the existence of electric oscillations and waves similar in character to those involved in the propagation of light, have been taken up by a number of investigators who have carried them out to a degree of accuracy which leaves little doubt of their actual existence.

At the beginning of his researches Hertz believed that he had found that the waves traveling within the wire had a speed equal to only .6 of that of light, although he gave this result as a mere provisory observation. This conclusion was not fully substantiated by the first experiment of MM. Sarasin and De La Rive, but these conscientious and dexterous experimenters were not satisfied with that. Judging that the dimensions of their laboratory at Geneva were too small to put the matter to a test, they tore down the partitions, but without modifying the result. Finally at the request of Prof. Hertz himself they decided to operate on a larger scale and removed their apparatus to the turbine room in the motive power station of the Rhone.

The accompanying engraving taken from *La Nature* shows the enormous scale of these experiments. At the right is shown the exciting apparatus which produces the oscillatory spark. The electro-dynamic action is propagated in all directions and strikes the reflector of zinc at a distance of 50 feet. This zinc reflector is 25 feet high and 50 feet long. The electrodynamic wave is thrown back on itself from the reflector, and in this way the ventral and nodal points of oscillation can be observed. For this purpose it is only necessary to shift backward and forward a small metallic loop, the ends of which almost close upon each other and leave only a small distance between the ends of the wire. At the nodal points nothing in particular is perceived; at the ventral points, however, the induced spark constantly plays between the small balls at the ends of the loop.

In order to observe in the dark and to operate more commodiously, the experimenters have constructed a tunnel of wood in the axis of which the phenomena can be observed, as shown in the illustration. The oscillator is shown in enlarged view at A, in the upper left hand corner of the engraving, and consists of two large spheres from which project two smaller ones which are immersed in oil. Knowing the distance from node to node, the length of the wave is deduced, being double that distance. Besides this, it is known how to calculate the number of oscillations per second to produce an action in the receiving loop, analogous to the acoustic resonator of Helmholtz, this loop, in fact, being called a resonator. This number multiplied by the length of the wave, as measured, gives the speed of propagation of the electrodynamic action, provided there is, of course, no error in the reasoning, but this is just the point upon which physicists are not yet entirely in accord.

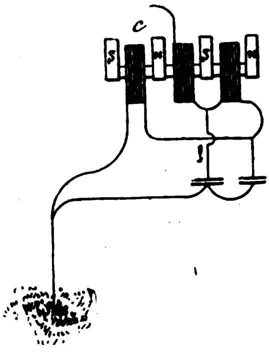


APPARATUS FOR STUDYING ELECTRICAL OSCILLATIONS.

Supposing it to be correct, however, MM. Sarasin and De La Rive have re established by their large installation the identical results which they had observed in their smaller ones, namely, that the speed of propagation of electrodynamic action in free air is the same as that along the length of the wires, that is to say, at their surface, while on the interior of the wire these waves are not propagated at all. By the processes sketched briefly above M. Blondlot has demonstrated in a direct way that this speed is equal to that of light.

The measurement of the speed of propagation of the electric waves in various media has also been made the object of very interesting researches. M. Cohn has found, for example, that the speed in water is 8.5 times smaller than that in air, and this is exactly the value of the index of refraction of water to electric waves found by M. Ellinger. The square of this number 72 is very nearly the value of the dielectric constant of water. The index of refraction of alcohol, equal to 4.8, leads to the same verification, and hence agrees with the theory of Maxwell.

THE FIELD VIBRATORY TELEGRAPH.



Field Non-Inductive Relay.

WHEN electric vibrations or undulations of a very rapid character are transmitted over a circuit it is found in practice that a distance limit over which reliable communication is possible is soon reached. This is especially the case in transmission of speech and in such systems of multiplex telegraphy as utilize a great number of vibrations or undulations on the line at the same time. In order to increase indefinitely the distance limit of such communication, Mr. Stephen D. Field provides transmitting apparatus which will produce greater fluctuations of the transmitting current, using relays to throw upon the distant section of the line vibrations or undulations of greater E. M. F. but of the same character as those received by the relays.

Mr. Field's invention comprises a receiver of great sensitiveness to electrical vibrations, capable of use as a receiver in a simple circuit or as a relay for repeating vibrations into other circuits.

For the purpose of raising the tension of the current so as to give the same a high E. M. F. and render it capable of overcoming a great line resistance, Mr. Field uses a dynamo with carbon brushes on its commutator and provided with two circuits, one of which is operated by the undulations the tension of which is to be raised, and the other connected to line circuit.

The damping effect produced upon vibrations of minute periodicity where a wire is coiled parallel to itself may be largely overcome by arranging a battery of small magnets in series, each of a size to accommodate the most minute impulses employed. The line currents after passing the first magnet find a return through a condenser provided between the coil or magnet and the one next in series, a more prolonged impulse serving to fill this condenser and energize the next magnet of the series, and so on through the set. To adapt this arrangement to the Field receiver the apparatus shown in the accompanying illustration is used. The current first passes through the centre coil, thence through the one to the right and finally that to the left, finding partial circuit in transit *via* the condenser.

ELECTRIC POWER IN DRIFT MINING.

THE electric power and lighting-plant installed by the Electrical Engineering Cpmpany, of San Francisco, for the Dardanelles mine, Placer county, Cal., says the San Francisco *Mining and Scientific Press*, consists of a 25-horse power Keith electric generator, a 6-h. p. electric pump, a 6-h. p. electric hoist and 50 incandescent lamps. The pump and hoist are operated by Keith motors. The electric plant was substituted for the cable transmission previously used.

By the substitution of power transmission by electricity, the expense has been reduced to the minimum, so that the initial expenditure for power has been decreased fully three-quarters.

During four months of each year steam power must be used, because the water power belonging to the mine is not then available. Three cords of wood were used each day to run the cable, but less than one cord is necessary by the electric system, even when the 25 electric lights in the tunnel and incline are continually lighted. The further saving of wear and tear is of much importance. No additional men to those otherwise employed in the mill and mine are engaged in operating the electric plant.

COLLEGE NOTES.

THE UNIVERSITY OF WISCONSIN is doing a most praiseworthy work in beginning a course of lectures by Dean Bryant of the College of Law, on law for engineers. The students in engineering will be given lectures by him on the law of corporations, the law of contracts, etc. Dean Bryant does this free of charge to the engineering students, who will doubtless show their high appreciation of his generosity by attending every lecture.

PERSONAL.

SCHUYLER S. WHEELER, Sc. D.[1]

Schuyler S. Wheeler, Sc. D.

Dr. Schuyler S. Wheeler, the electrical expert, Board of Electrical Control of New York City, and president of the well-known firm of the Crocker-Wheeler Electrical Company, was born in New York City, May 17, 1860. He is the son of James E. Wheeler, of Waterloo, N. Y., and Amrie W. Wheeler, his wife. He was prepared for college at the "Friends' Seminary," Keble Hall, and Columbia Grammar School, and was graduated from Columbia in 1881. Since leaving college, Hobart College has conferred on him the honorary degree of Doctor of Science.

Dr. Wheeler has written numerous papers on electrical engineering; and two supplements to *Harper's Weekly* on "Electrical Lighting." He is also in part author of the standard work entitled "Practical Management of Motors and Dynamos" (Crocker & Wheeler, 8vo.; D. Van Nostrand & Co., 1892). He has been vice-president of the Civil, Mechanical and Electrical Engineers Societies, and is also a member of the National Electric Light Association.

Dr. Wheeler is in politics a Mugwump, and is a member of the University Club.

Upon leaving Columbia College in 1881, Mr. Wheeler became assistant electrician of the American branch of the Jablochkoff Electric Light Company. When that company dissolved, he joined the United States Electric Lighting Company, and subsequently left them to become a member of Mr. Edison's staff.

Mr. Wheeler was present at the inauguration of the Pearl Street Edison Station, was made electrician in charge, and was detailed to lay the underground systems in other cities.

He afterwards became superintendent of the Newburgh Edison Company, resigning that position to accept the post of electrician to the Herzog Teleseme Company. Mr. Wheeler subsequently joined the C. & C. Electric Motor Company as electrician and factory manager. After establishing the large factory of this company, he accepted the appointment of Electrical Expert of the Board of Electrical Control of New York, an important official position in which he has been called upon to superintend the removals of all the overhead wires in the city, a work which has taken over four years, and has been much talked of in the papers. During this time about 50,000 miles of wire and 8,000 poles have been removed. He has also been called upon to make expert examinations and reports for the city upon all cases of electrical accident.

PROF. E. J. HOUSTON.

At the last meeting of the New York Electrical Society, Prof. E. J. Houston, of Philadelphia, was elected an honorary member in recognition of his long and eminently successful and useful career in the field of electricity.

Mr. W. T. Mottram, of Dallas, Tex., and for a long time agent in the South-West for the Edison and General Electric interests, has removed to New Orleans and has been appointed electrical engineer of the New Orleans Traction Company, which is about to undertake a large amount of trolley line construction, beginning probably with its Prytania street branch. Mr. Mottram is a young engineer of unusually ripe experience, and well qualified for his new work.

Mr. A. Mitchell Hall, heretofore in the sales department of the C. & C. Electric Motor Company, of New York, has now assumed the position of general manager of the company.

LETTERS TO THE EDITOR.

SUGGESTIONS FOR THE INTERNATIONAL ELECTRICAL CONGRESS AT CHICAGO.

Certain amendments to the Report of the Special Sub-Committee of the American Institute on Provisional Programme for the International Congress of 1893, should, it seems to me, be made. Referring to the programme issued by the Institute, page four now reads: "The value of the practical unit of illumination to be a bougie-decimale at the distance of one metre. The bougie-decimale is the unit of light and power already established, and is practically equal to one English Standard Candle." Page five: "For the practical unit of illumination defined above the name bougie-metre."

The first part of this being already established, ought probably to stand, but the second part, that quoted from page five, ought, it seems to me, to be changed to read "For the practical unit of illumination defined above, the name 'Davy.'" Davy was the first discoverer of electric lighting properly so called; has a short name, and was known and honored by all nations; his name is, I conceive, much more appropriate than "bougie-metre" which is clumsy.

On page nine the clause now reading, "The north pole of a magnet to be defined as being that which seeks the geographic north pole, and the south pole that which seeks the geographic south pole," is incorrect and requires change. I think the following would be better: "The north pole of a magnet to be defined as being that which in a magnet poised to swing freely in a horizontal plane seeks the terrestrial north magnetic pole,, and the south pole that which seeks the terrestrial south magnetic pole."

I consider that the proposed use of the term "voltage" in place of the terms potential, tension or pressure, and as a synonym, would not be an improvement; for why should we name a magnitude in terms of its unit? Or, if in one case, why not in other cases also, calling resistance "ohmage," current "amperage," and quantity "coulombage," thereby becoming consistent? Besides, electromotive force and difference of potential are not always interchangeable terms, both, however, being measurable and expressed in volts.

On the same page the proposal to substitute "continuous current" for "direct current" I consider should not be complied with. It gives no idea of direction, but does give the idea of continuity. If it should be adopted generally, a rapidly intermitting current, that is to say, a discontinuous current would be called a "continuous current" provided it was of uniform direction. I do not think the term "direct current" is beyond criticism, but it is better than its proposed substitute.

T. D. Lockwood.

Boston, Mass., Jan. 27, 1893.

IS LIGHTNING A CAR ARRESTER?

In your issue for Nov. 16, '92, Vol. XIV, No. 237, p. 480, Mr. Alex. Jay Wurts says:

> "In many of our cities and towns, particularly in the Western sections of the country, it has been common practice during thunder storms to shut down the plant, pull down the trolleys and wait till the storm shall have spent itself. In one case, with which I am familiar, the direct losses from enforced idleness during thunder storms amount to over $6,000 per year."

The above statement has been copied in the English journals, and it would be of interest to know something of how far such practice *is* (?) or *has been* (?) *common.* Who will give names of roads, make of apparatus and detail of delays per year? The information would certainly be of interest.

J. Stanford Brown.

New York City, Feb. 9, 1893.

SOCIETY AND CLUB NOTES.

SUBURBAN UNDERWRITERS' ASSOCIATION.

At the meeting of the Executive Committee of the Suburban Underwriters' Association, held on Tuesday, Feb. 7, Mr. Fremont Wilson was appointed as consulting electrician for said Association. Rules governing the installing of electric light, heat and power installations have been recommended, and are the same as those recommended by the United Association of Underwriters' Inspectors, of which Mr. C. M. Goddard, of the New England Exchange, is secretary. The territory at present under the jurisdiction of this Association is Queens, Suffolk, Westchester, Putnam and Rockland counties. Richmond County is practically under the jurisdiction of the Association, and the same rules and regulations will undoubtedly be required there. Any information which parties may desire will be furnished by Mr. H. E. Bowers, secretary of the Association, 44 Pine street, New York City.

BADGES AT THE ST. LOUIS CONVENTION.

THE distinguishing badges to be worn by the officers of the N. E. L. A. at St. Louis have been announced as follows:

President, gold button, red bow; officers, Association button, silver, red bow; executive committee, same button, blue bow; active members, same button, purple ribbon; associate members, same button, violet ribbon; honorary members, same button, white ribbon; reception committee, same button, yellow ribbon; guests, olive ribbon.

LITERATURE.

De Magnete. By William Gilbert, M. D. Translated by P. Fleury Mottelay. *New York*, John Wiley & Sons, 1893. XLV +, 368 pp. 6 x 9 inches. Cloth. Price, $4.

IN our issue of January 18, we reviewed this work from the advance proofs kindly furnished us by the publishers. The complete volume is now before us and to our commendations for the work of the translator, already expressed, we must now add our avowal of admiration at the style in which the publishers have submitted the work to the reading public. The letter press is printed on heavy book paper, in large type, and all the engravings are reproduced in fac-simile and full size from the original issue of 1600. Additional interest is afforded by the fac-simile reproductions of the title pages of the 1628 and 1633 editions of the De Magnete, and of the posthumous "De Mundo Nostro Sublunari" of Gilbert, which have been embodied at the end of the work.

The book is beautifully bound in white cloth with gilt top, and bears the arms of Gilbert in gilt on the front cover. From both a scientific and an artistic standpoint, this translation of De Magnete is in every way worthy of its great author.

Electrical Experiments. By G. E. Bonney. *London & New York;* Whittaker & Co., 1893. 252 pp. 5 x 7 inches. Cloth. Price, 75 cents.

THIS book is intended as a guide to young experimenters who desire to make their hours of amusement profitable. It describes in clear language, accompanied by numerous illustrations, a large number of simple electrical experiments, extending over the whole range of applied electricity.

How To Manage the Dynamo. By S. R. Bottone. *New York;* Macmillan & Co., 1893. 63 pages 5 x 7 inches. Cloth. Price, 60 cents.

THE author has sought to give dynamo attendants plain directions as to the management of their machines, and the location and remedy of troubles. So far as the latter is concerned this part has already been done better in previous publications.

OBITUARY.

GEO. B. PRESCOTT, JR.

IT is our sad duty to record the death, on Feb. 12, of Mr. Geo. B. Prescott, Jr., after an illness of nearly a year and a half. He was the eldest son of Alphonso and Harriet A. Prescott and a descendant in the eighth generation from James Prescott who came from Dryby, Lincolnshire, England, and settled in Hampton, N. H., in 1665. He was born at Pittsfield, Mass., in 1858, a year in which his parents removed with him to Milwaukee and afterward to Ottawa, Ill. His father enlisted in the War of the Rebellion, was made lieutenant of the 104th Illinois Volunteers, and was captured by Morgan's Guerrillas. After these stirring episodes the family settled in St. Louis, where George B. remained until he came to New York in 1876, when, through the influence of his uncle, George B. Prescott, a prominent electrician in the service, he became connected with the Western Union Telegraph Company under such an admirable instructor as George A. Hamilton, while Mr. F. L. Pope gave him lessons in drawing, in which he became quite expert. Mrs. Pope noticed his ability and encouraged him in the study of mathematics. In 1880 Mr. Prescott resigned his position with the Western Union and entered the laboratory of Mr. Edward Weston, at Newark, N. J., where he assisted actively in the varied pioneer work on dynamo, arc light and incandescent lamp construction then being so diligently prosecuted by Mr. Weston; and quite a number of patents issued to Mr. Prescott date from that period. Mr. Prescott had from the beginning devoted special attention to the storage battery, with the result that in 1889 The Electrical Accumulator Company, offered him the position of electrician to the company, which he accepted and held until early part of 1891, when he assumed the agency for A. G. Day, manufacturer of "Kerite" wires. It should be mentioned that in 1887-8 he fitted up and operated the pioneer electric car of the West End Company of Boston.

Up to 1891 Mr. Prescott had been engaged in purely professional work but the sudden assumption of duties involving large business and financial responsibilities appears to have borne very heavily upon one who had always been of a highly nervous disposition. The result was a nervous prostration which compelled Mr. Prescott to abandon all business for a while. In order to fully recover his health he removed to Pittsfield, Mass., and returned for a short while to professional work in the Stanley Experimental Laboratory; but continued ill health induced him to seek the milder climate of Bermuda. Unfortunately the sought-for improvement did not take place, and when Mr. Prescott returned a few weeks ago it was only too apparent that he was beyond recovery.

Naturally quick of perception, Mr. Prescott possessed that rare quality which coördinates facts and by which he was enabled to employ his knowledge to the best advantage. He was a frequent contributor to THE ELECTRICAL ENGINEER and other electrical and lay journals, and was the author of the well-known Copper Wire Table published by Messrs. Holmes, Booth & Haydens, which passed through numerous editions.

Mr. Prescott was from the beginning prominently connected with the American Institute of Electrical Engineers and was a member of its council for a number of years. He was also a member of the Standard Wiring Table Committee of the Institute, a large part of whose report embodies his work and research. In 1888 Mr. Prescott was married to Miss Frances Russell Cooley, of Pittsfield, Mass., who survives him.

COST OF MUNICIPAL ELECTRIC LIGHTING

IN the course of an article entitled "Electric Street Lighting in American Cities," in the February *Review of Reviews*, Mr. R. J. Finley says: "The average cost of each arc light owned and directly operated by twenty-five cities is $53.04 a year. In the case of only three or four of the cities, does it appear that interest on the investment has been included. Obviously, account should be taken of both interest and depreciation of property, which items, computed at twelve per cent. of the total value of the twenty-three plants and buildings, would add $33.60 to the first cost, making the average final cost to the twenty-three cities operating electric lighting plants $86.64 per arc light per year.

There is one important factor that has not been considered in this cost, namely, the profits which many of the cities receive from light supplied to private and commercial houses. Eighty dollars per light per year will be found to be much nearer the real cost of municipal electric lighting in the United States if the receipts from commercial lamps are deducted.

THE WORLD'S FAIR "SCRIBNERS."

CHARLES SCRIBNER'S SONS are preparing a novel and interesting contribution to the World's Fair in the form of an "Exhibition Number" of *Scribner's Magazine*, to be published simultaneously with the opening of the Exposition at Chicago. They have planned to make it as fine an example of an American Magazine as can be produced by a house to whom the best literary and artistic resources are open. It is not proposed that the text shall relate chiefly to the Fair, but, on the contrary, the leading writers and artists have been asked to contribute to the number what they themselves think will best represent them. The pages of text and illustration will be largely increased.

THE CHICAGO EXHIBITION.

MR. H. D. WILKINSON has been appointed engineer to the British Section of the Chicago Exhibition, and will sail on or about the 20th prox. Mr. Wilkinson is "an old Exhibition hand." At the Paris Exhibition of 1889 he was in charge of Messrs. Davey, Paxman & Co.'s exhibit, in 1891 he was responsible for the electric lighting of the Naval Exhibition, and at the Crystal Palace Exhibition of last year Mr. Wilkinson also held an important post.

THE TROLLEY ON THE ERIE CANAL.

A BILL has been introduced in the New York Legislature by Mr. Rice, authorizing Sherman Petrie of Kings County to use the Erie Canal to experiment with the trolley electric system as a motive power for canal-boats, the experiments to be made at Mr. Petrie's expense, under the supervision of the State Superintendent of Public Works.

WESTERN OPINION.

A READER in Iowa writes: "I have taken THE ENGINEER for several years and consider it the best in its line."

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEBRUARY 7, 1893.

Conductors, Conduits and Insulators :—

Telephone Cable, S. W. Holman, Boston, Mass., 491,109. Filed Nov. 5, 1892.

A cable composed of two or more twisted pairs of conductors, each pair having a twist of different pitch from that of any adjacent pair.

Insulator Clip, W. H. Edmunds, New York, 491,208. Filed Aug. 9, 1892.

A semi-circular clip adapted to half surround the insulator and having wedge-shaped hooks at the ends for the reception of the line wire.

Insulator, A. R. Lane, New York, 491,362. Filed May 18, 1892.

Consists of two insulating blocks between which the wire is held, supported in a metal frame and having a screw pressing upon the upper block.

Method of Insulating Electric Conductors, T. E. Morford, Chicago, Ill. Reissue. 11,303. Filed June 8, 1892.

Employs an enamel of non-conducting material imbedding the conductors.

Dynamos and Motors :—

Bipolar Electrical Machine, T. H. Hicks, Detroit, Mich., 491,106. Filed Feb. 8, 1892.

Employs field magnets wound with two sets of coils, one set in series with the external working circuit which is supplied with alternating currents, and the other set of coils on the field magnets supplied with currents direct from the armature; both sets acting mutually to maintain the field of force.

Dynamo Electric Machine, G. V. M. A. Parrot & A. C. Reignier, Paris, France, 491,294. Filed Aug. 8, 1892.

Employs an armature constructed of strips, each composed of a rod of iron and one of copper, superposed upon another.

Electrical Transmission of Power, C. S. Bradley, Avon, N. Y., 491,465. Filed Apr. 4, 1892.

Invention relates to the transmission of continuous currents over long distances, and consists in placing a large number of generators in series thoroughly insulated from one another and from the earth, and transmitting the combined electromotive force of all the machines to line.

Insulation of Dynamo Armatures, T. E. Morford, Minneapolis, Minn., 491,490. Filed Jan. 28, 1891.

Employs an insulating enamel adhering to the core and imbedding the coils.

Heating :—

Electrically Heated Soldering Iron, S. B. Jenkins, Boston, Mass., 491,311. Filed June 8, 1892.

Electrically Heated Smoothing Iron, S. B. Jenkins, Boston, Mass., 491,312. Filed June 8, 1892.

Electric Curling Iron Heater, S. B. Jenkins, Boston, Mass., 491,313. Filed June 8, 1892.

Hat Brim Softening Device, W. Mitchell, Malden, Mass., 491,319. Filed June 8, 1892.

An electrically heated device for use in the manufacture of hats.

Electrical Water Heater, W. Mitchell, Malden, Mass., 491,320. Filed June 18, 1892.

Electrically Heated Vessel, W. Mitchell, Malden, Mass., 491,321. Filed June 8, 1892.

Electrically Heated Gridiron, W. Mitchell, Malden, Mass., 491,322. Filed July 2, 1892.

Electric Metal Heating Device, W. Mitchell, Malden, Mass., 491,437. Filed June 16, 1892.

Electrically Heated Muffle, W. Mitchell, Malden. Mass., 491,438. Filed July 5, 1892.

Electrically Heated Vessel, S. B. Jenkins, Boston, Mass., 491,484. Filed June 9, 1892.

Measurement :—

Electrical Measuring Instrument, E. G. Willyoung, Philadelphia, Pa., 491,457. Filed Aug. 11, 1892.

Claim 18 follows:

In a measuring instrument for measuring electrical currents, the combination of an expansion wire, a pointer actuated thereby, a compensating support for the expansion wire having its ends provided with means for holding the wire in tension, and an intermediate frame for sustaining the support of the wire.

Miscellaneous :—

Retouching Device, A. S. Harry, Steubenville, O., 491,171. Filed Nov. 15, 1892.

Electric Clock, J. H. Dyson, Belleville, Wis., 491,339. Filed June 6, 1892.

Electro-Mechanical Movement, E. Gray, Highland Park, Ill., 491,345. Filed Jan. 8, 1892.

Electric Lock, O. A. Moyer and H. W. Rhodes, Ogden, Utah, 491,369. Filed April 9, 1892.

Process of Electrically Reducing Aluminum and Forming Alloys Thereof, T. L. Willson, Brooklyn, N. Y., 491,394. Filed March 25, 1891.

Combined Electric Switch and Door Lock, J. H. L. Holcombe, U. S. Navy, 491,426. Filed Oct. 24, 1892.

Insulated Magnetic Coil, T. E. Morford, Minneapolis, Minn., 491,491. Filed Jan. 28, 1891.

Employs an enamel imbedding the coil.

Resistance Box, E. Weston, Newark, N. J. Design, 22,207. Filed Sept. 10, 1892.

Lamps and Appurtenances :—

Electric Arc Lamp, W. E. Freeman, Long Island City, N. Y., 491,095. Filed July 8, 1892.

Claim:

The combination with the spools, the rocking frame and the cores, of the clutch levers, embracing the carbon carrying rod, and the cam on the rocking frame, whereby the levers are operated.

Arc Light Carbon, J. McLaughlin, Chicago, Ill., 491,124 Filed May 5, 1891.

A carbon consisting of a plurality of separated members integrally joined at one end.

Duplex Electric Arc Lamp, C. E. Scribner, Chicago, Ill., 491,251. Filed Oct. 20, 1890.

Employs upper carbon rods adapted to move in unison and lower carbons one of which is fixed and the other movable and controlled by an electro-magnetic device in circuit with the fixed carbon holder.

Lamp Socket, E. R. Elliott, Litchfield, Ill., 491,268. Filed March 28, 1892.

A key operated by an endwise movement of a shaft across the lamp socket.

Railways and Appliances :—

Inclosed Conductor for Electric Railways, F. C. Perkins, Dunkirk, N. Y. 491,182. Filed May 27, 1892.

An insulated supply conductor for traveling contact enclosed in an elastic metallic tube adapted to be compressed by the traveling contact to establish electric connection with the conductor.

Trolley Stand, S. Harris, Cleveland, O., 491,210. Filed Nov. 14, 1892.

Consists of a stationary base provided with an upright hub, a housing having a sleeve concentric with the hub, and an inner loose sleeve with a series of anti-friction rollers in the annular chamber between the inner sleeve and the hub.

Electric Railway Trolley, B. Kochs & A. Kochs, St. Louis, Mo., 491,361. Filed July 25, 1892.

A reversible trolley pole carrying two trolleys swiveled upon the pole in such a manner as to be capable of a vertical oscillatory movement independent of the yoke which carries them.

Electric Circuit for Railway Signaling, L. Thaler, New York, 491,337 Filed Aug. 24, 1892.

An electric block system for steam railways.

Switch for Electrical Tram Cars, M. Immisch, London, Eng., 491,483 Filed Nov. 21, 1891.

A self-locking switch for street railways.

Telegraphs :—

Printing Telegraph Receiver, M. D. Porter, Brooklyn. N. Y., 491,133. Filed Dec. 10, 1891.

Vibratory Telegraphy, S. D. Field, Yonkers, N. Y., 491,163. Filed Jan. 7, 1892.

Claim 1 follows:

The combination of a local circuit including signal transmitting device, a line circuit and low and high tension coils connected to the respective circuits, said coils being in inductive relation to the magnetic system of a continuously operating dynamo electric machine.

Telautograph, E. Gray, Highland Park, Ill., 491,347. Filed Sept. 21, 1892,

Claim 1 follows: The combination of a motor, a telautographic receiving pen driven thereby, and a magnetic clutch through which the power of the motor is transmitted to the driver mechanism, said clutch consisting of two members each of magnetizable material, one having a rotary and the other a rectilinear action.

Telephones and Apparatus :—

Testing Apparatus for Multiple Switchboard Systems, C. E. Scribner Chicago, Ill., 491,250. Filed Sept. 9, 1890.

Employs a pair of loop plugs and cords, and branch from the strand of the cords, connecting the sleeves extending through the winding of the clearing-out annunciator.

Metallic Circuit for Multiple Switchboard Systems, J. A. Seely, New York, N. Y., 491,252. Filed Nov. 15, 1886.

Invention consists in placing the different magnets of each of the clearing out rods in different strands of the cords, so that the resistance of the two sides of the metallic circuit may be balanced.

Telephone Transmitter, H. L. Tyler, Corning, N. Y., 491,275. Filed May 13, 1892.

Employs a non-conducting diaphragm having a hook secured to it and a carbon chain connected to the hook, the chain being not only a conductor but from its link construction adapted to vary the intensity of the current flow.

Multiple Switchboard System, C. E. Scribner, Chicago, Ill. Reissue. 11,306. Filed Nov. 6, 1891.

Employs a retardation coil in a ground branch extending from one side of the metallic circuit.

THE PREPARATION OF INCANDESCING FILAMENTS.

ACCORDING to the *Zeitschrift für Electrotechnik*, the Buda-Pesth Incandescent Lamp Company have introduced some important modifications into the manufacture of incandescent lamps. The uncarbonized filaments of wood, cotton or other vegetable fibre are first immersed in a bath containing 25 to 30 per cent. of potassium silicate, 10 to 15 per cent. of gum arabic, and 12 to 13 per cent. of caustic soda. After removal they are rolled to the section of an angle iron which is said to give a strong filament with a considerable surface. The filaments are then carbonized, after which they are mounted and placed in a bath of melted paraffin or naphtaline. After the latter has become solid by cooling, a current is passed through the filaments, melting and vaporizing the paraffin in their immediate neighborhood, and causing a deposit of carbon, as in ordinary flashing. It will be seen, however, that by this method the carbons can be standardised before being placed in their bulbs. Liquid paraffin is said not to work, as convection currents are then established in the bath, which bring all the oxygen entangled in the bath in contact with the filaments, sparking them. The solution in which the filaments are soaked before carbonizing is said to protect them during carbonization, and to give them a uniform surface, on which carbon can be deposited during the flashing process. The gum arabic is also beneficial, the filaments being stronger after carbonization when it is used. When the resistance of the filaments has been brought to the proper point by the flashing process, they are removed from the bath, and any excess of paraffin or naphtaline sticking to them is washed off with alcohol.

A TELE-TYPEWRITER TOURNAMENT.

A FAST-SENDING and typewriter-receiving telegraph tournament will be held in Hardman Hall, this city, on March 11. The contest will be divided into several classes and several prizes in money are offered. For the championship of the world a medal, valued at $200, will be given. The entrance fee has been fixed at three dollars for each class.

Communications should be addressed to W. S. Williams, secretary, care of the Postal Telegraph Company, 187 Broadway, New York city.

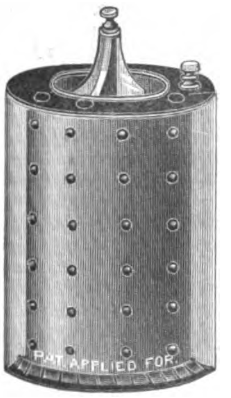
THE FRENCH PACIFIC CABLE.

THE French Ministry, at a council held at the Elysee on February 4th, approved the proposition to lay a cable from the French colony of New Caledonia to Australia.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE PREMIER-DE MOTT BLUE STONE BATTERY.



PAT. APPLIED FOR.

The Premier-De Mott Blue Stone Battery.

THE accompanying engraving represents a new type of blue stone battery just brought out by Mr. M. R. Rodriguez, of 17 and 19 Whipple St., Brooklyn, N. Y. This battery is intended for operating electric devices for long periods of time, Type "A" 5 x 7 inches being adapted for driving electric fans, turn-tables, etc., and Type "B," 6 x 8 inches, for telegraph or signal work.

The cells are furnished with a special zinc which forms no hard coatings, so that they can be readily cleaned with a piece of cloth. The zincs, it is claimed, will last 1,500 hours and need not be taken out of the solution.

These cells have run the No. 3 Premier motor for 200 hours, night and day, and 400 hours at ten hours a day, at a total cost of less than 50 cents.

Mr. Rodriguez also manufactures the Premier cell adapted to be used in connection with bichromate solutions of all kinds, and having 70 ampere hours capacity at two volts. Two such cells will run a 1 c. p. incandescent lamp for 30 hours at a cost per charge of 6 cents.

THE DELAWARE HARD FIBRE COMPANY.

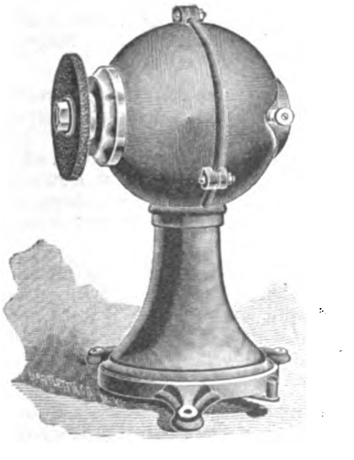
THE "hard fibre" made by the Delaware Hard Fibre Company, of Wilmington, Del., is a vegetable substance closely resembling horn in structure. It possesses the strength and density of a metal and yet is elastic and nearly as light as hard wood. It is insoluble in any of the ordinary solvents and is unaffected by contact with alcohol, ammonia, turpentine or the animal, vegetable or mineral oils. When immersed for some time in water it will absorb it and swell, but is in no way injured, and upon drying it resumes its former size and density.

An important property of hard fibre is that when pure and dry, it is an excellent insulator. This fact, in connection with its physical properties adapts it for many uses in electrical construction. It may be sawed, worked in a lathe or planer, riveted, punched, drilled and tapped and will take a fine polish, in addition to which it is not brittle but on the contrary very tough, and will stand a great amount of pounding and rough usage.

A noteworthy feature of this material is that it improves with age. For electrical work fibre that has been cured for six months or a year gives the best results.

The uses to which this substance is applicable are many, and the company, in their new catalogue, show scores of different devices, among which are insulators, brush holders, switch handles, fuse blocks and others of especial interest to electricians.

SMALL LUNDELL MOTOR AND EMERY GRINDER.



Lundell Motor and Emery Grinder.

THE fact that the small, as well as the larger sized Lundell power motors manufactured by the Interior Conduit and Insulation Company, of New York, have been and can be adapted to many useful purposes, is again exemplified in the new bench emery grinder which this company has just standardized. The accompanying cut illustrates this neat little machine, which will at once commend itself to machinists and others interested in the grinding of small tools, such as twist drills, lathe tools, graving tools, knives, scissors, etc. All shops that have adopted electric illumination can conveniently use this device. The emery grinder illustrated is 12 inches high, weighs 18 lbs., operates at a speed of 2,500 revolutions maximum, and has in its base a regulating device for two lower speeds. It is of $\frac{1}{6}$ h. p. capacity, 115 volts and swings a two-inch emery wheel. Larger and smaller wheels driven by motors of higher or lower powers, are also furnished by the same company.

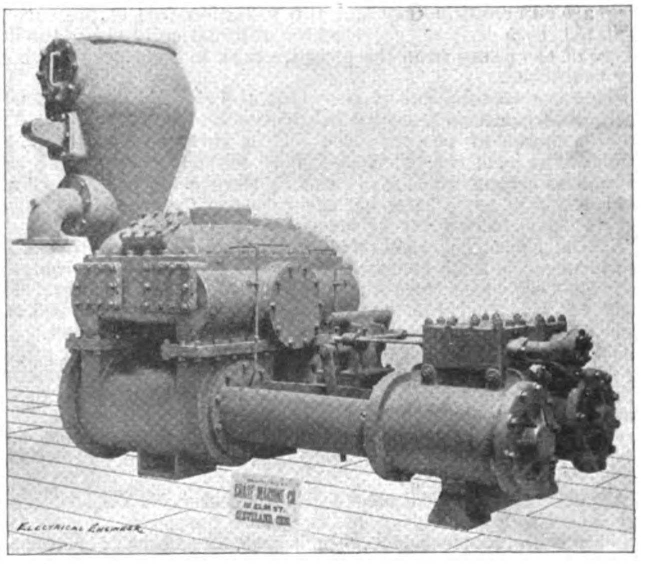
PROGRESS IN ELECTRICITY BUILDING, WORLD'S FAIR.

IN the electrical building the Western Electric Company has partially completed a handsome gothic pavilion in which an attractive exhibit will be made. One of the features will be a long distance telephone, connected with a high sounding board through which concerts given in New York and other distant cities can be enjoyed by visitors in the amphitheatre in which the instrument will be placed. Next to this pavilion the Bell Telephone Company and the Edison Company and the telegraph companies will put up handsome booths to show the development of the telephone, telegraph and electrical apparatus generally.

THE CHASE CONDENSER PUMP.

THE CHASE MACHINE COMPANY, of 111 Elm street, Cleveland, O., are furnishing the Detroit Electric Light & Power Co. a condenser pump, the steam cylinders of which are 12 inches diameter 15 inches stroke. The cylinders are 15 inches diameter by 15 inches stroke, and the weight of the machine complete, is 10,150 pounds. The piston rods are 1¾ inches in diameter of solid Tobin bronze. The air or heater cylinders have cast composition, reversible levers, composition valve seats and pins, and hot water rubber valves.

The water pistons are arranged for packing with six rings of ¾ inch square hydraulic packing, and are easily reached from the back end of the cylinders by removing the cylinder heads and piston followers. The spray is self-cleaning, or rather is operated from the outside of the vacuum chamber, and is said to be unique in this respect. The steam end of this pump is similar to those of other well-known machines, as the accompanying engraving shows.



CHASE CONDENSER PUMP, DETROIT ELECTRIC LIGHT AND POWER COMPANY'S PLANT.

A NEW ISOLATED PLANT FOR ST. LOUIS.

THE Consolidated Engineering Co. with offices in the Security Building, St. Louis, secured the contract last week for the entire installation of the new arc and incandescent plant to be placed in the Globe Clothing & Shoe Company's establishment. The arc lighting portion goes to the Standard Electric Co. of Chicago, and consists of two 40-light machines, while two 400 light direct current machines will be furnished by the National Electric Manufacturing Co. of Eau Claire, Wis. Power will be furnished by two 108 h. p. Russell engines. When completed, there will be no better lighted store in the country. Some novel features in lighting will be introduced by the Consolidated Engineering Co. in the installation of this plant.

CARPENTER HEATERS FOR A STEAMER.

THE CARPENTER ELECTRIC HEATING MANUFACTURING COMPANY of St. Paul, Minn., D. Richardson, general manager, reports that it is in receipt of an order from the American Steel Barge Company, West Superior, Wis., for a complete equipment of electric cooking utensils for the new whaleback World's Fair passenger steamer "Columbus." The order was given after a careful examination and test of the apparatus. The steamer will be the first ever equipped with electric cooking appliances.

GOULD TRIPLEX PUMPS.

AMONG the recent installations of Triplex power pumps, by the Gould Manufacturing Co., of Seneca Falls, N. Y., is one just installed in the Fireman's Insurance Building, Baltimore, Md., by Messrs D. E. Evans & Co., of that city.

The problem for solution was the operation of an Otis hydraulic passenger elevator, which had been formerly run by city water, by means of an electrically operated pump. The plant consists of a 15 h. p. Thomson-Houston motor belted to an 8-inch x 8-inch triplex pump which maintains a pressure of 80 lbs. in a 1,500-gallon pressure tank, the control of the motor and pump being effected by a Clark regulator furnished by the General Electric Co. The pump is speeded at 40 revolutions per minute and maintains a uniform pressure of 80 pounds in the pressure tank, and upon the starting of the elevator, the regulator is so nicely adjusted that the pump and motor start with a variation of a few pounds from the normal pressure.

From the data collected regarding the power, consumption, etc., it is calculated that the power for ten hours a day for a month, does not exceed five to six h. p., a very economical rate for operating an electric elevator for office buildings, and the apparatus is so arranged that in case of a break-down at the power station, the city water can be instantly turned on and the elevator run by its pressure until electric energy is again supplied.

At A. Schwartz & Son, New Orleans, is another very complete electro-hydraulic pumping plant, consisting of two hydraulic passenger elevators for a building five stories high. The pumping plant consists of one 8-inch x 10-inch triplex pump operated with 25 h. p. Eddy motor maintaining a pressure of 80 pounds in a 3,000 gallon pressure tank. In this plant the motor and pump are run continuously and the variation in the pressure is regulated by a by-pass valve which automatically shifts the discharge of the pump from the pressure tank to the waste tank as may be desired.

Since the installation of the plant, the elevators have been in continuous operation from ten to twelve hours per day. The actual amount of power consumed in this plant is 16¼ h. p., which at the local rate of power cost makes a very cheap and economical arrangement for operating the elevators. A very unusual work is performed by the pressure tank, in blowing a whistle three times a day by means of the accumulated air.

At the Fulton Worsted Mills, Fulton, N. Y., two 8-inch x 12-inch pumps are be to operated with 15 h. p. motors for supplying the mills with water from a source some 25,000 feet distant. The plant is so arranged that the pump and motor can be stopped and started automatically from the mill when occasion requires.

Ordinarily the pumps will be in continuous operation, pumping direct to tank for mill supply. In the cost of installation and operation of this style of pumping outfit, as compared with a complete steam pumping appliance with the necessary attendance, is very largely in favor of the electrical pumping plant. It is so arranged by means of clutch couplings that either one or two pumps can be operated.

At the state industrial schools, at Rochester, N. Y., is another very interesting application of electrical pumping. From two artesian wells 200 feet deep, 6 inch bore, 50 gallons of water per minute are raised by means of power working head operated with electric motors. The water is lifted the 200 feet and then forced into a pressure tank against a pressure of 80 pounds per square inch. The pumps and motors are run continuously and when a normal pressure of 80 pounds is obtained in the pressure tank, an automatic arrangement consisting of a by-pass valve is put in opertion which shifts the water from pressure tank to suction, thus consuming little or no power in operating the pumping mechanism when tanks are filled.

Possibly one of the largest and most extensive electric pumping plants will be installed at the water works of San Antonio, Texas. This plant consists of three 10-inch x 12-inch triplex power pumps, each operated with a 30 h. p. C. & C. motor; the combined capacity being 2,000,000 gallons per 24 hours. The water is taken from four artesian wells 8 inches in diameter and 2,500 feet deep having a combined capacity of 4,000,000 gallons per day.

From the pumps, the water is discharged through a 22 inch main into a reservoir situated three miles distant and to a vertical height of 195 feet above the pumps. At present the electric power is generated in the local power station of the town, but ultimately when the total water supply of the town is installed, which will be 10,000,000 gallons per day, the electric power will be generated by water-wheel situated three miles distant from the pumping station. The motors are geared directly to the pumps and are arranged with such automatic devices as are necessary to run the machinery at any desired speed to meet the varying requirements of the city's supply.

At Portland, Oregon, there are probably in use more electric hydraulic pumping plants than in any other city in the country. Among the most notable installations is that in the Oregonian Building. At this place one 10-inch x 12-inch triplex power pump operates two large passenger elevators, two side-walk lifts and one freight elevator. The pump discharges into a 3,000 gallon pressure tank, maintaining a uniform pressure of 100 pounds per square inch.

The motive power is a 75 h. p. Edison motor, which in addition to running the 10-inch x 12-inch triplex power pumps, operates a large Hoe printing press and other machinery connected with the printing outfit. The discharge to the pressure tank is automatically regulated by means of a by-pass valve which is made to shift the water from pressure tank to open tank as the pressure reaches its normal amount. This plant is in operation 24 hours per day and the elevators and other machinery are in constant motion. The plant has been preëminently successful; the consumption of power of the daily running coming within the prescribed limit of the guarantee and the expectations of the engineers.

A similar plant is in operation at the Worcester Building, in which two large passenger elevators for a seven-story building are operated with 10-inch x 12 inch triplex pump in combination with a 40 h. p. C. & C. motor. Here the pump discharges into a 5,000 gallon pressure tank and maintains a uniform pressure of 100 pounds for the operation of the elevators. The average consumption of power for operating these elevators is 18¼ h. p. for the whole day.

WESTERN NOTES.

THE ILLINOIS ELECTRICAL FORGING COMPANY has just been incorporated with a capital of $2,000,000. Walter G. Campbell of San Francisco is president, L. D. Kneeland, vice-president and John P. Skinner, of New York, secretary and treasurer. The offices will be in the Title & Trust Building, No. 100 Washington street, Room 401, Chicago, Ill. This company will do all kinds of electrical forging, smelting and welding, and will be located at West Pullman.

Mr. Campbell, the president, has been interested for the past few years in mining in the far West and has a vast experience with ores. Mr. Kneeland, the vice-president, is also vice-president of the West Pullman Company and a large stockholder.

MR. W. R. MASON, the General Manager of the Railway Equipment Company, Chicago, has just sent out a circular to the eastern trade, calling attention to the unequalled facilities of the company for furnishing everything necessary for the complete equipment and maintenance of electric roads, and also calling particular attention to the merits of the Type "G" overhead material manufactured by his company. This material has been specified on a majority of the leading roads during the last season. He also informs the trade that he expects to be in New York the latter part of this month, and will call on the leading contractors and street roads in the East.

AMONG a number of sales recently made by the Chicago office of the Ball Engine Co., of Erie, Pa., are the following :

Calumet Electric Street Railway Co., Chicago, four 300 h. p. cross-compound electric railway engines ; Hammond Electric Street Railway Co., Hammond, Ind., one 150 h. p. steam plant complete ; H. D. Bentley. Freeport, Ill., one 35 h. p. steam plant complete ; Elmwood Electric Light Co., Elmwood, Ill., one 150 h. p. engine ; Union Passenger Station, Chicago, one 125 h. p. engine ; Keith Bros. & Co., Chicago, one 50 h. p. engine ; Marengo Electric Light Co., Marengo, Iowa, one 100 h. p. steam plant complete ; Scott & Royce, Griggsville, Ill., one 50 h. p. steam plant complete ; Western Light & Power Co., Chicago, one 300 h. p. engine ; Englewood Electric Light Co., Chicago, one 500 h. p. cross-compound engine.

THE CENTRAL ELECTRIC COMPANY are looking about for new quarters in which to house the large stocks of supplies which they purchase, and which their increasing business compels them to carry in order to meet the requirements of their trade and fill their orders with promptness. They report having their eye on several large buildings which will enable them to handle their stock with increased facilities. They have recently added largely to their force, and predict a large trade for the spring.

THE ENTERPRISE ELECTRIC Co., 307 Dearborn street, reports that their local business has increased to such an extent that it has been necessary to secure a delivery truck of their own. In this, as in all the supplies they handle, they wanted the best, and placed their order with Belnap, Esseler & Company, of Detroit, Michigan. The Enterprise Company wish to call the attention of their numerous customers to the fact that they can now guarantee the prompt delivery of all orders.

THE NEW ACME lamp adjuster for regulating the height of incandescent lamps, which is being placed on the market by the Electric Appliance Company, is meeting with a ready sale. The adjusting mechanism, in the form of a rosette, is attached to the ceiling instead of being suspended on the cord, thus giving it a neater appearance and making a more substantial arrangement.

F. G. FULLER, Western sales agent of the U. S. Wire & Cable Company has just closed a large contract with the World's Fair people for rubber insulated cable to be used for power transmission at the World's Fair. This order will amount to about $50,000. There was some spirited competition commensurate with the securing of this handsome order.

THE ELECTRIC APPLIANCE COMPANY report a lively and growing demand for their adjustable electrolier illustrated in another column. They state that, judging from the way the orders come in, it will almost entirely displace the old style cord adjusters.

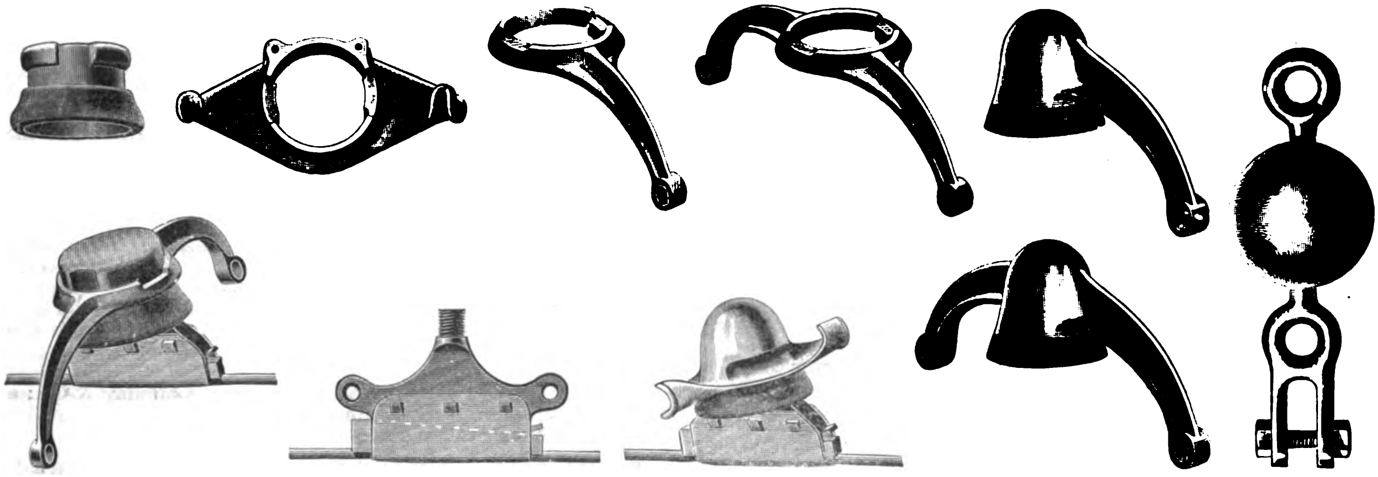
STERN & SILVERMAN.

The new departure made by the above firm of 707 Arch St., Philadelphia, is being noted with a great deal of interest. They will make a specialty of the design and construction of electric railway, light and power plants, a work for which their long years of experience qualify them very thoroughly. Mr. W. A. Stern was for fourteen years connected with the Edison interests, beginning in the employ of Mr. Edison himself at Menlo Park. He then represented the Edison Company in the Pittsburgh district, being prominently connected with the Edison General and General Electric companies, and having charge of the railway department. The firm of Stern & Silverman was formed about three and a-half years ago to develop this work, and made a great success of it, Mr. J. H. Silverman, who has had seven years' in the field, being general manager of the Pittsburgh office for the Pennsylvania General Electric Company.

Under their new auspices, the firm will design and build plants and do expert work. They will not confine themselves to any system or set of apparatus. March 1 they will open their fine store at the above address, carrying a full line of fixtures, chandeliers, etc., occupying also a very large basement and extensive rear building. They know the territory very well, and will push for trade far beyond their old lines.

THE NEW YORK ELECTRICAL WORKS.

The New York Electrical Works, of 161 Washington street, have added to their already long list of specialties for electric railway line construction, and we are now enabled to illustrate certain improved devices not included in the recent article on the same subject in The Electrical Engineer.



Figs. 1 to 10.—Electric Railway Line Material of the New York Electrical Works.

Fig. 1 shows the new universal bell, fitted with $\frac{5}{8}$-inch bushing to fit a mechanical clip or strain-ear. Figs. 2, 3, and 4 represent hangers to fit this bell, making a straight-line hanger, single and double pull-offs. Figs. 6 and 7 show the clip attached. Fig. 5 is a frog pull off.

Figs. 8 and 9 show the insulation moulded into the old forms of straight-line hanger, etc., all in one piece, while Fig. 10 shows a modification of the mechanical clip into a strain-ear.

The advantage claimed for the devices represented by Figs. 1, 2, 3 and 4 is that in case of accident of any kind to the insulation or clip they can be removed and replaced without in the least interfering with the span-wires.

The locking device is a wedge dropped into a slot, and is very simple and effective, while at the same time easily removed without damage.

The Medbery insulation is used exclusively by this company and is giving the most satisfactory results in actual practice.

ACTIVITY AT THE DETROIT ELECTRICAL WORKS.

The Detroit Electrical Works have started in on the spring season in excellent shape and with great activity. They are doing a good trade and making new friends steadily. Some of their recent orders for street railway equipment have been large, including one from the Detroit Citizens Street Railway Company, which has contracted for 60 motor equipments, for its road.

Mr. L. E. Myers, hitherto the special agent for the works at Chicago, has been made District Manager and is to carry out an aggressive policy in developing business in the territory over which he has jurisdiction.

PHILLIPS INSULATED WIRE COMPANY.

Mr. H. C. Adams, the new president of the Phillips Insulated Wire Company, of Pawtucket, R. I., has opened offices at 39 and 41 Cortlandt street, which will hereafter be the headquarters of the company. Mr. Adams's wide experience and acquaintance among electrical business men will greatly add to the strength of the company.

The "O. K." brand of weatherproof insulated wire, manufactured by the Phillips Insulated Wire Company, is claimed to stand the best insulation test, and is made of Lake Superior copper and very handsomely finished.

PROGRESS OF THE CHICAGO EDISON COMPANY.

The Chicago Edison Electric Illuminating Company stockholders have decided to increase the capital stock of $1,500,000 to $3,000,000. This is due to the recently consummated purchase by the Chicago Edison people of the Chicago Arc Light and Power Company. The standing of the Edison Company is very high, its stock being now quoted at 205. President Insull has been East the past week on important business connected with the affairs of the company.

SHAWMUT FUSE WIRES.

We have received advance proofs of a pamphlet to be issued shortly by the Shawmut Fuse Wire Company, of 161 High street, Boston, Mass., which contains some most interesting and valuable information on this important subject. The pamphlet describes the principles governing the action of fuse wire, and shows the necessity of correct proportions in length and diameter to attain proper results. A number of diagrams are given illustrating the points brought out.

HEISLER ELECTRIC COMPANY.

The Heisler Electric Company, Drexel Building, Philadelphia, Pa., contemplate having a strong delegation at the National Electric Light Association meeting on Feb. 28, in St. Louis.

The company has been very busy of late in the manufacture and sale of its standard apparatus. For some time past it has also been at work upon a regulating socket for use on electric lighting circuits, and this it expects to put upon the market very shortly.

"ENERGY."

The advertisement that has appeared recently in our pages, offering the services of a young lawyer who is desirous of making a start in the electrical field is one that deserves notice, and we can heartily recommend companies in need of such talent to communicate with the advertiser. He is a man to be taken up and utilized.

Mr. W. F. Collins, formerly the Western representative of The Electrical Engineer, and now business manager of *The Western Electrician*, has been in New York and the East for several days calling on personal and trade friends. He has met with a cordial reception everywhere, and goes home with bright expectations of even greater prosperity for his progressive journal.

THE SILVEY STORAGE BATTERY FOR LIGHTING CARS AND FOR TRACTION.

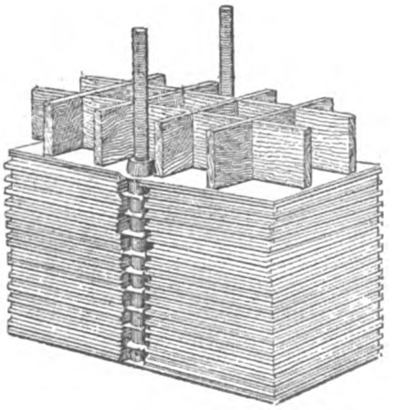
For some time past, passenger cars on the Chesapeake and Ohio and Atchison, Topeka and Santa Fé Railroads have been lighted by current taken from the Silvey storage batteries carried on the cars. According to the *Railroad Gazette*, the first-named road now has in use 30 cars which are lighted in this way. They are all charged at Covington, Ky., and make trips as far as New York and Old Point Comfort. Each car has eight lamps of 16 candle power inside and one lamp on each platform. The accompanying cut shows the general appearence of the battery plates as arranged in a cell.

The battery plates proper consist of a metal grating 6 x 12 inches square, and about ½ inch thick, 21 of which constitute a complete battery cell. These lead plate castings are laid on their sides in a bath, and by an electrical process filled with electrolytically deposited spongy lead, after which they are placed in a bath which hardens the spongy lead into a firm coherent mass; it becomes firmly fixed into the holes and forms a surface layer over the entire plate. The plates are next assembled in proper number to constitute a complete battery. The plates are clamped together by means of a lead screw passing through the hole in the plate as shown, a nut being placed between each two plates, and firmly screwed down. By this means a good metallic contact is made and soldering is unnecessary. In case it ever becomes desirable to take the cell apart, it is easily done by removing these nuts.

The plates are separated by sheets of porous material which has been treated with acids and alkalies, which make it practically indestructible in the electrolyte. The sheets are capable of absorbing more than four times their own weight of the acids used in the battery, which in fact becomes nearly a dry cell, or, in other words, there is very little free liquid to become spilled, and should the rubber cell ever become broken the liquid held in suspension in the separating material is sufficient to operate the lights properly during a trip. In order to prevent any possible splash of the free liquid on top of the battery plates, the cell is made very deep, the plates only filling about half its depth, and as an additional precaution a sort of wooden crate, shown in the cut, is laid on top of the plates, dividing the interior of the cell into small pockets, preventing the formation of waves by any jar of the car.

The cars are all independent of each other, each car being provided with its own batteries, which renders the system very flexible. It has been found in practice that the batteries will light the cars for three nights at one charging so that they are capable of lighting a train through a journey of 2,000 miles. The battery is the invention of Mr. W. L. Silvey and is built by the Dayton Manufacturing Company, of Dayton, O.

The officers of the roads using these batteries are not yet prepared to give detailed statements concerning the cost of the lights. The running expenses have thus far been very reasonable, but, as with all storage batteries, the average cost for any extended length of time depends in large measure upon the cost of renewing the battery, and this is as yet an indeterminate amount for the reason that the first batteries put in have not yet been renewed.



The Silvey Storage Battery.

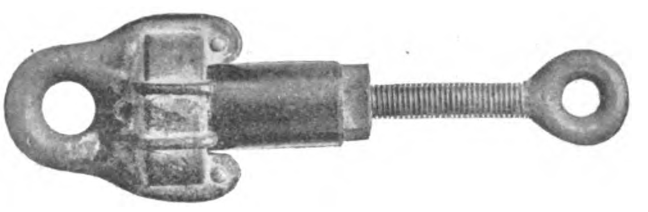
In addition to the above, it may be stated that it is proposed to use the Silvey battery for traction purposes on one or two new electric roads in Ohio.

FORD-WASHBURNE CARS FOR CLEVELAND, O.

We are glad to report, on advices from Mr. C. J. Swift, the business manager of the Ford-Washburne Storelectro Company, that the company has closed a contract with the Woodland Avenue and West Side Street Railway Company for five 30 h. p. street railway equipments of the new flexible connection, single reduction type, one motor to the car.

THE ANDERSON STRAIN INSULATOR.

The accompanying illustration shows the "Brooklyn" strain insulator, manufactured by Messrs. A. & J. M. Anderson of Boston, and recently tested by the Massachusetts Electrical Engineering Company with such satisfactory results. Five of the insulators, submerged for 12 days in salt water were subjected to three tests each. The resistance on the first day was found to range in the five specimens from 160 to 600 megohms; after washing it rose to from 8,000 to 110,000 megohms; and, after drying for ten days, reached 25,000 megohms in the worst specimen and 300,000 megohms in the best. One of the specimens was tested for strength and broke at a load of 7,280 pounds, giving way around the circumference of the iron head.



The Anderson Strain Insulator.

FLOORING THE NORTH RIVER WITH KERITE CABLES.

W. R. Brixey, proprietor of Day's Kerite, Mail and Express Building, has taken a contract to lay two cables each 5,300 feet long from Barclay street, New York, across the North River to Morgan street, Jersey City, for the Metropolitan Telephone Company. They will be 18-conductor submarine telephone cables similar to the seven previously laid by Mr. Brixey for the same company and the Long Distance Telephone Company. These cables are giving fine service, and Mr. Brixey proposes to maintain the high standard of the old work in the new.

PHILADELPHIA NOTES.

Mr. H. S. Buddy, manager of the isolated lighting department of the Penn. General Electric Co., reports a wonderful increase in the business of his department over last year. Among some of the recent important installations are the following: A 75 kilowatt multipolar direct driven machine, 1,500-lights, for both the Bijou Theatre and Hotel Metropole. These machines are a new type and *slow speed*, making but 275 turns. A 1,000-light plant each for the new *Times* Annex and Hensel, Calloday & Co.; a 600-light plant each for Geo. Allen's millinery store, and the City Passenger Railway Co. of Baltimore.

The Heisler Electric Co. report a steady growth in the sale of their long distance incandescent lighting apparatus. Among some of the towns recently adopting their system are the following: Gonzales, Tex.; Seguine, Tex.; Brownville, Tex.; Edwardsville, Ill.; Hanover, Pa.; Lorely, Md.; Chestertown, Md., and Baltimore, Md. They have also installed a 1,500-light combination storage battery plant in the new Provident Building at Fourth and Chestnut streets.

Mr. C. K. Westbrook, formerly with the General Electric Co. and now located at Walnut and Third streets, is offering for sale a patent on a coal cutting machine. The field for coal mining by electricity is very promising. If the machine will do what Mr. Westbrook has claimed for it the patent is a valuable one.

SOUTHERN NOTES.

The Milton Electric Light Company, Milton, Pa., are putting in a 100 h. p. Ball engine, furnished by J. M. Parker & Co., Philadelphia representatives of the Ball Engine Company, Erie, Pa.

The New Castle Steel Company, New Castle, Pa., are placing a 200 h. p. Ball engine, manufactured by the Ball Engine Company, Erie, Pa.

Messrs. S. Bergmann & Co., of Fenn Strasse 21, Berlin, Germany, have issued a profusely illustrated catalogue of interior conduit, fixtures, switches, fuse blocks, etc. The catalogue contains 72 pages and is handsomely gotten up.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XV. MARCH 1, 1893. No. 252.

AN HISTORIC EDISON PLANT.

THE S. S. "COLUMBIA."

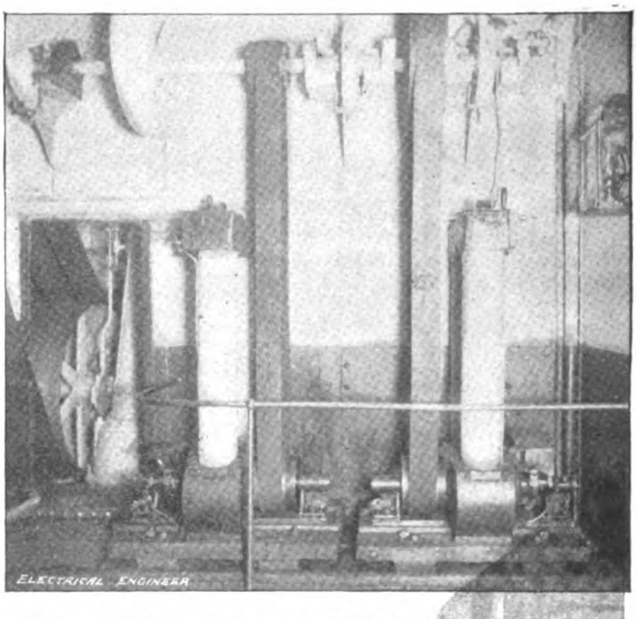
J. C. Henderson.

SHIP lighting by electricity is now a very common and ordinary thing, but time was when the plant installed on board the steamship "Columbia" of the Oregon Railway and Navigation Company was a great marvel. And yet that plant was started as recently as May 2, 1880. It has never been illustrated before, and its story is not very well known. It appears that in 1879 President Henry Villard conceived the idea of lighting each room on board the new steamer "Columbia" by the electric light. The project was certainly a plucky one, but Mr. Villard never wanted for courage. By his orders, and under suggestions from Mr. Edison himself, Mr. J. C. Henderson, then advising engineer of the Oregon Company, wired the new ship with No. 11 wire for mains and No. 32 wire for branches, the wire being "underwriter's" insulated by double cotton paraffine, painted over all. There were four dynamos, one of which was run as an exciter for the others. All these machines were driven from a countershaft directly overhead, the countershaft belting to a pair of vertical engines at a very high angle to economize freight space. Our illustration gives a good idea of this arrangement.

In 1882 Mr. Henderson made an interesting report on the plant, from which we quote the following as to the lamps: "The first lamps used, being of the paper carbon variety, were irregular in their duration of life and so liable to breakage by heavy shocks that I found it best to suspend them from the wires above, and to do away with sockets entirely. The lamps being surrounded with a ground globe, the attachment was hid, the lights being suspended from the ceiling. Since the arrival of the ship on the Pacific coast we have received a full supply of new bamboo carbon lamps."

It may be mentioned that the paper carbon lamps first installed were delivered on board personally by Mr. Francis R. Upton, who brought them directly from the factory, with jealous care, and saw to their installation and the running of the wires, plant, etc, in New York, before the steamer started. Some of the experiences on the "Columbia" led to the introduction of safety fuses. Mr. Hiram Maxim saw some of these lamps on the "Columbia" in New York, and started out on his own incandescent work. The connection thus casually formed with the electric light industry by Mr. Henderson, led in time to the concentration of his energies on it, making him ultimately engineer-in-chief of the Edison General Electric Company. Thus, it will be seen, quite a chapter of electrical history gathers around the "Columbia" Edison plant, officially described in one of the old Edison bulletins as being "the first ever put in operation in the hands of strangers." The only ship lighting plant that could compete with this as a pioneer in the art was that built for the unfortunate exploring steamer *Jeannette*, and now lying in the cold depths of the Arctic Ocean.

Since the plant was thus put in for the "Columbia," hundreds and thousands of other steamers have been equipped with the incandescent light, but the advantages of the system have never since been more clearly pointed out than they were by Mr. Henderson himself in his official report exactly 10 years ago. The first point he made was that of economy, because "the light does not require the services of an attendant for trimming, lighting, etc., and there is less breakage." His next point was freedom from danger, "no matches being required." The extent to which the incandescent light has been a factor of safety on shipboard is in reality remarkable. As to ventilation Mr. Henderson remarked that "it is not necessary to keep doors and windows shut on account of smoking lamps or to prevent their being blown out." He dwelt also on "cleanliness and absence of disagreeable odor," and remarked that "the advantage of a non-smelling light at night in sick rooms is manifest." All this is true, but the incandescent light has so thoroughly gained the day that the argument has no longer to be made on these lines. In fact, there is no need to make an argument at all, for a first-class steamer not equipped with electricity is something one cannot imagine, and an absolute contradiction in terms.



DYNAMO PLANT ON BOARD THE S. S. "COLUMBIA," 1880.

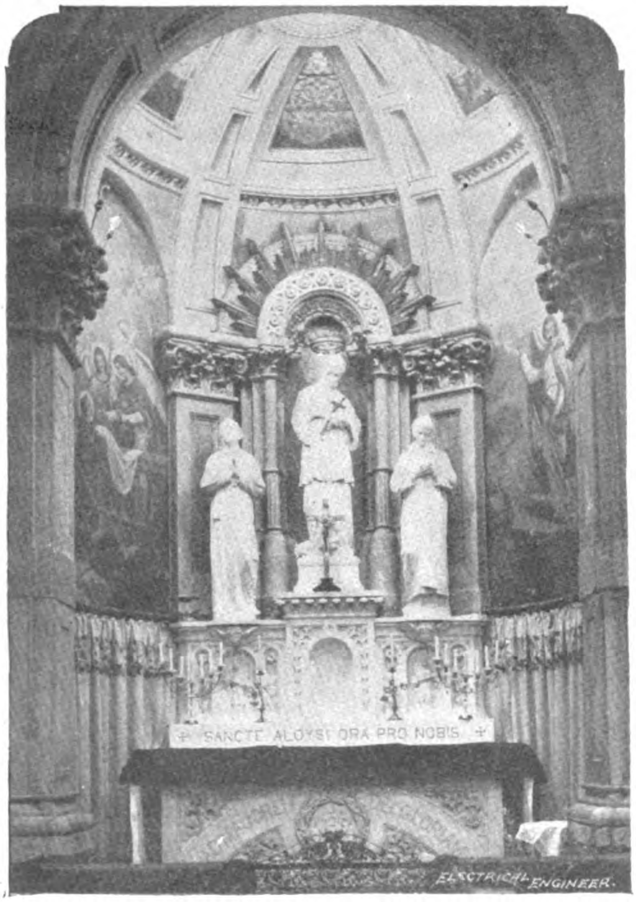
ELECTRIC LIGHTING IN CHURCHES: ST. FRANCIS XAVIER'S, NEW YORK.

BY

John McGhie

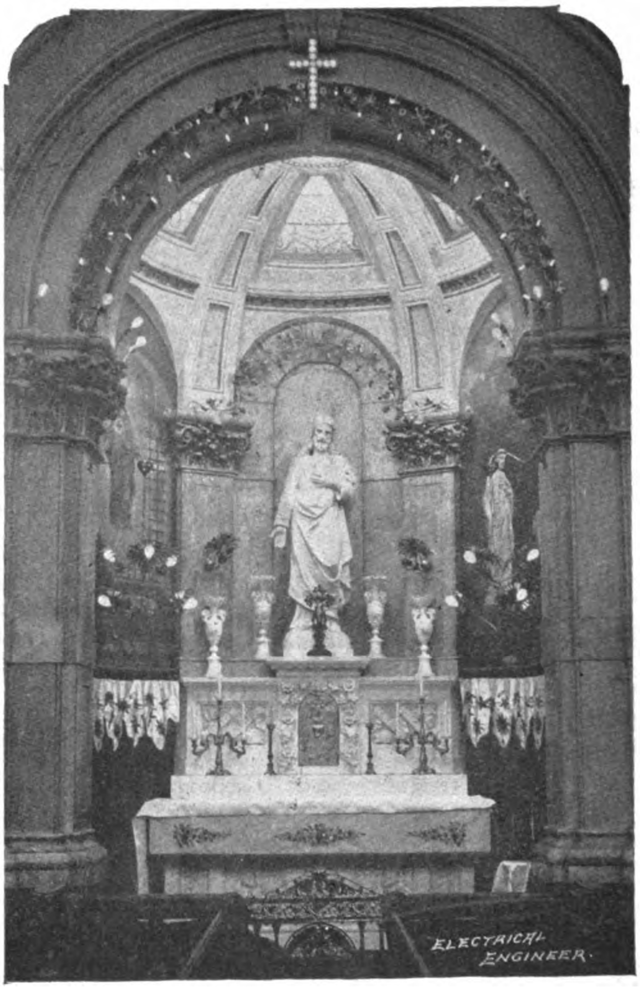
The electric installation in the church of St. Francis Xavier on West Sixteenth street, New York City, just completed, is an excellent example of the adaptability of the great illuminant to the enhancement of ecclesiastical architectural effects. Undertaken with many misgivings on the part of the Jesuit Fathers in charge as to whether it would infringe the rubrics, the task of electrically lighting the church from the pavement to the point of the arched roof has been accomplished with complete success, and St. Francis Xavier's, when fully lighted, has already become one of the unique and notable sights of the metropolis.

This church resembles nearly all other churches in its cruciform character, having the main altar at the apex of the cross, and chapels at each of the extremities of the transept. It is built in the Florentine renaissance style, and the florid, intricate stonework decoration lends itself admirably to the additional decorative effect of the electric light.



St. Aloysius' Chapel, Church of St. Francis Xavier.

On entering by the principal door beneath the great organ, the eye is confronted by a blaze of light from the high altar, and the alcove in which it is set. Three semicircles of numerous incandescent lamps spring from the capitals of the three rows of pillars superposed one upon the other. The uppermost semicircle is continued around the entire church, above the capitals of the first tier of columns above the gallery. Around the capitals of the first tier of columns springing from the pavement, the brilliant lights are also run, illuminating all the obscure corners of the structure, and effecting a wonderful change in the picturesque aspect of the interior of the building. The fixtures used to support the lamps and bring about this beautiful effect consist of small lengths of curved and polished tube, springing in graceful lines from the upper surface of the abacus of the columns, their juncture with the stonework being concealed by a border of polished metal. So closely together are the lights set that the double lines of light around the church seem continuous.



Electric Illumination of Chapel, Church of St. Francis Xavier.

The marble work immediately surrounding the tabernacle on the high altar has been worked in from behind, and in the recesses thus made incandescent lamps are set. These are lighted in the presence of the Host. A similar effect is obtained by concealed lights in the tourette. On each side of the high altar steps are two alabaster vases, from each of which spring six lilies. In each vase are two incandescent lamps. The stems of the lilies are of polished metal, the flower itself is a specially designed shade of opalescent glass, and the stamen is a frosted tubular lamp. When the current is thrown on to these pieces the effect is indescribably beautiful.

Above the pulpit on the outer edge of the sounding board is a silver dove in descending flight, laid against the background of a golden star. Concealed behind the star is a 50 c. p. lamp which floods the preacher and pulpit with a bright light as soon as the circuit is closed.

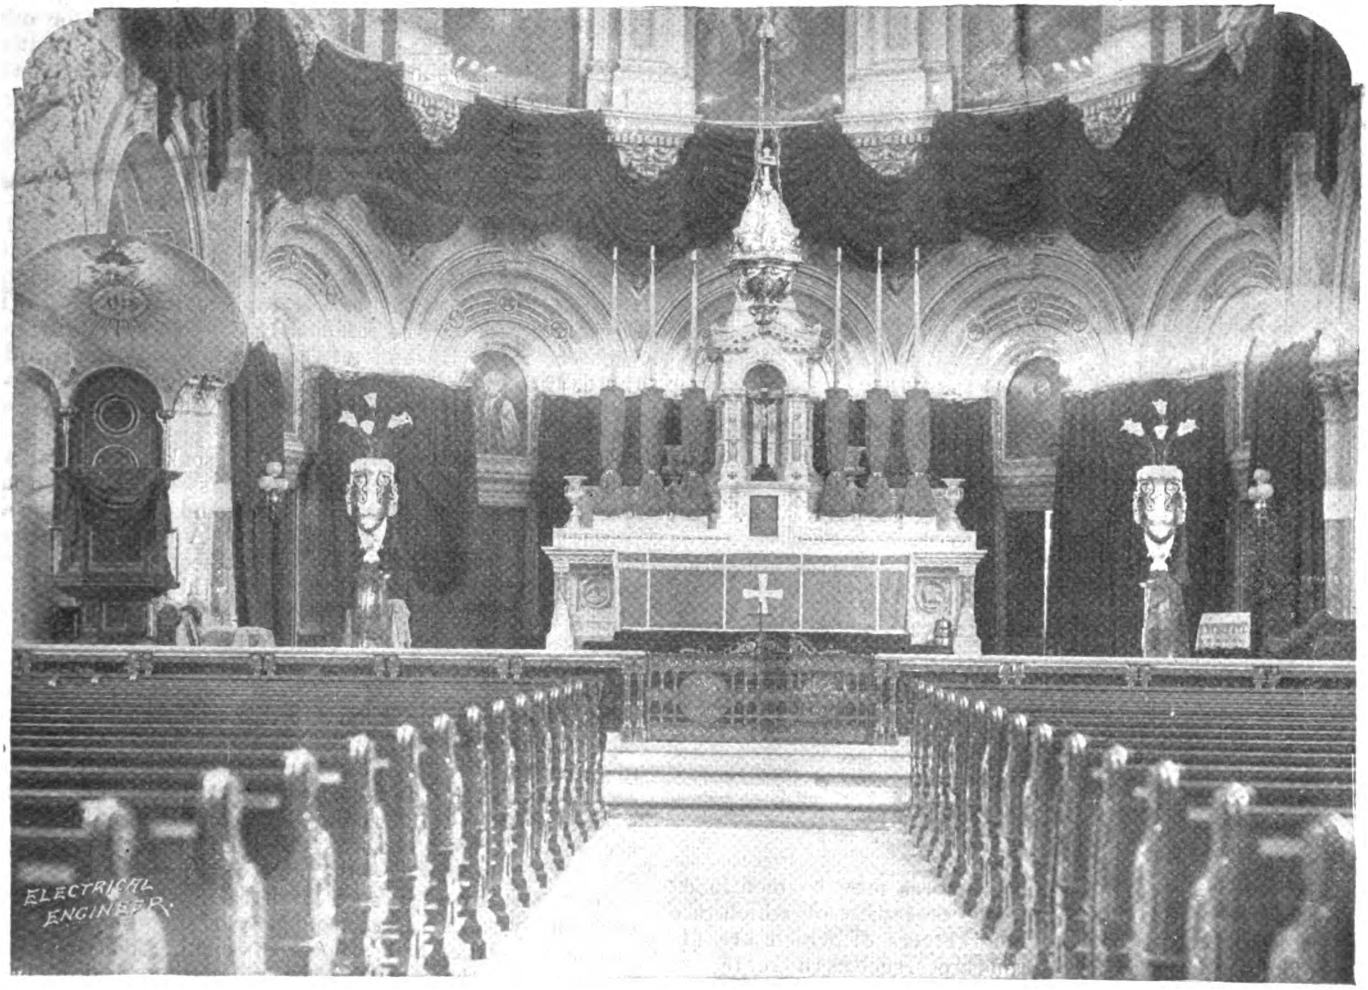
It is in the lateral chapels that the Saints-Pères have allowed their artistic proclivities to make themselves most manifest. In the Virgin's chapel to the left of the grand altar, the pendant crimson light has been removed from the centre where it obstructed the vision of the effigy of the Virgin and Child, and is now suspended from a handsome silver bracket at the side. Around the upper part of this chapel, and concealed from view, is a row of lights which shed a soft radiance over the Mother and Infant and the many floral offerings that are continually laid upon the small altar steps.

The chapel at the left extremity of the transept is, however, the most æsthetic of all. The same effect of concealed source of light behind the coping of the arch, is also employed here, but there are additions which render this chapel unique. Immediately above the head of the marble Christ runs a metal structure in the form of a grape vine, grapes and leaves being reproduced in the metal with faithful exactitude of color and form; in the centre is a bunch of wheat ears. This symbolizes the doctrine of transubstantiation in the Eucharist. Hanging from each side of the chapel are brackets of palm-leaves made of red hammered copper. These are the palms of martyrdom. Running over the outside of the arch is a passion-flower vine, each flower and each leaf perfect in its reproduction in hammered metal, the whole surmounted by a cross of incandescent lights—the cross of Constantine.

Immediately opposite this chapel is that of St. Aloysius, the principal feature of which is the crown of gilded metal studded with miniature lamps held over the Saint's head by two cherubs.

The crypt underneath the church has also been fitted with electric lights, as was the College theatre, recently destroyed by fire. In all there are about 2,000 lights in the church itself, while those in the other portions of the structure bring up the total to about 500 more. The photograph of the high altar was taken on the occasion of the funeral of Patrick Gilmore.

The current is derived from the street mains of the Edison Electric Illuminating Company, the wire being led to a slate switchboard in the sacristy at the rear of the high altar. The lamps are all divided into small groups each of which is controlled by its switch on this board. By this means the principle of economy in the consumption of current is not lost sight of.



ELECTRIC LIGHTING OF HIGH ALTAR, CHURCH OF ST. FRANCIS XAVIER, NEW YORK.

The decorative fixtures are all the work of the General Fixture Company, successors to the Fixture and Decorative Bronze Department of the Edison General Electric Company. They were made under the personal supervision of Mr. J. T. Robb. The wiring and all the work connected with the installation was in charge of Mr. D. Colombani, with whom the idea of thus lighting the church first originated and to whose energy the success achieved should be attributed. In effecting this installation many and serious difficulties were met with, but all have been surmounted and it is as an example of a perfectly lighted church that St. Francis Xavier's can be cited.

Virgin's Chapel, Church of St. Francis Xavier.

INSULATED ELECTRIC CONDUCTORS.—XIX.

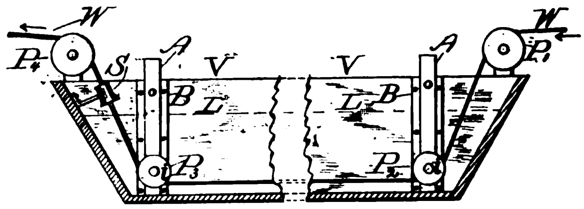
BY

James Bewstead Williams M.E.

As varieties of weatherproof wires may be mentioned those having dielectrics, the outer layers of which are saturated braids, and the inner layers of which are (1) previously prepared non-fibrous tapes, such as rubber tapes; (2) indestructible fibre, such as asbestos, with the interstices filled with *any* insulating material; and (3) a wrapping of prepared yarn, such as cotton saturated with paraffine. As further varieties of this general class of wires we may have those with coverings formed (1) of braids saturated with *solid* material which can be liquified by heat, such as ozokerite, bituminous matter, etc.; (2) unspun fibre, applied by wrapping and saturated with insulating material, *e. g.*, cotton applied while in the form of sliver and saturated with tars, pitches, etc. If this fibre is fine and is wrapped while wet it makes, when dry and saturated, an exceedingly tough covering. Its insulation resistance, like that of *all* prepared fibrous coverings, will, of course, depend upon the absence of moisture in the fibre, the kind of materials used, and the care taken during manufacture. And (3) fibre bound together with vulcanized compositions. In fact, the coverings of weatherproof wires may, and often do, consist of *any* combinations which do not readily change by exposure to the atmosphere. But if the coverings do not possess *insulating* properties, of what use are they? Simply protecting a copper wire from the air does not make it less dangerous when conveying high tension currents. The same question might be asked with reference to a fireproof covering that does not insulate well. If we make the bulk of a covering of asbestos fibre, *e. g.*, to be of any *practical* value the covering must be a complete one, and must *insulate* the wire. In order to do this the space between the fibres must be filled with a good and suitable insulating material and the fibre imbedded in the same. What kind of material shall we use for this purpose? The writer has never succeeded in finding a highly insulating material that was both fireproof and of practical value. If we fill the spaces with any *good* insulating material it will burn or be ruined by overheating, if an opportunity occurs, and what is the result? The material is either ruined at once or soon becomes so, in consequence of the overheating it has received. True, the *body* of the covering, if it be formed of asbestos, spun glass, or other non-inflammable materials, may remain unchanged, but the spaces which *were* filled do not fulfill their function,—that of making the covering a perfect envelope—the first fog or rain charges or fills them with moisture and the wire becomes dangerous. What we need are fuses, and promptly acting ones at that, rather than fireproof coverings if we wish to escape any damage which would be caused by an excessive current being suddenly thrown into circuit. *Any* insulated wire, if it becomes overheated from any cause whatever, will also overheat its covering; the insulation resistance of the covering will rapidly diminish and if the current on the wire be sufficiently strong an arc will form between this wire and any conducting body connected to earth with which the covering of the wire comes in contact. The consequences of such an event are only too well known.

A simple and convenient way of soaking the braids on several wires at one operation is to pass the wires through the same vessel containing the paint and thence to the different braiders for the outer braids. A reference to drawing, which is a vertical longitudinal section of such a vessel and its accessories, will show how this is done. $P_1 -- P_4$ are loose, deeply-grooved, pulleys; S is any suitable stripping device for removing the superfluous paint from the fibre before the wire W leaves the oblong vat V; L indicates the level of the liquid; A is a beveled strip in which the ends of the rod *i*, on which the pulleys turn, is fixed, and which can be secured to the sides of the vat by a bolt or otherwise; and B is a grooved strip fastened to the vat, and in which A can be moved up or down whenever it is necessary to remove the pulleys from the liquid, etc. If six wires are to be soaked it is evident that there must be at least six pulleys $P_1 -- P_4$ and six strippers. The pulleys on each rod are separated from each other by washers so each pulley can turn independently of the others.

The apparatus and process of soaking can readily be understood without any further explanation. Soaking braids in vessels separate from the braiders, although it may take a little more time, is to be preferred for these reasons: 1. The fiber remains longer in the solutions. If we allow an average speed of 50 feet per hour for a braider—in practice it is usually less—we can easily calculate the length of time the fibre can remain in a vat of a given length. 2. The fibre can be absolutely dry just as it enters the



Trough for Soaking Braids.

liquid. 3. But one vessel requires attention for a number of wires. 4. The soaked braid can be passed through a drying chamber between the vat and braider. By using certain kinds of paint, the soaked fibrous layer or layers can be dried, or nearly so, before the outer braid is applied. 5. There need be no leakage or spilling of the solutions. The stuffing boxes in the vessels attached to braiders are always liable to permit leakage and consequently a spattering on the machines or floor. 6. The fuzz on the fibrous layers can be more effectually removed. There are other reasons, but those given must suffice.

If it is desired to allow the fibre to remain a considerable length of time in the liquid reels containing the braided wires can be immersed in tanks or vats and the wires drawn off the reels, which revolve on rods like the pulleys, to the braiders or other apparatus for the final treatment. If the vat V, were provided with a steam-jacket or other means for heating its contents, *any* suitable material which could readily be liquified by heat could be used for saturating the fibre on wires in the same manner as the paint.

INFLUENCE OF FREQUENCY ON THE WORKING OF ALTERNATE CURRENT TRANSFORMERS.—II.

BY

Chas. Steinmetz.

From the plotted curves of magnetizing current and iron loss values were taken in equal intervals, and collected in the accompanying table, for comparison, giving for the three different frequencies the $E =$ E. M. F. in volts effective, $C =$ magnetizing current, in amperes effective, $W =$ losses in iron, in watts.

Since the magnetization, or magnetic induction B, is proportional to $\frac{E}{N}$ because $E = \sqrt{2}\,\pi\, n\, N\, s\, B\, 10^{-8}$, where s is the iron cross-section, N the frequency, n the number of turns, therefore in the table the values are arranged so that values corresponding to the same $\frac{E}{N}$, that is, the same magnetization, stand in the same line, and the value $\frac{E}{N}$ is given in the first column of this table.

TABLE OF ALTERNATING CURRENT TRANSFORMER TESTS AT DIFFERENT FREQUENCIES.

	$N = 204.5$ periods.				$N = 137.5$ periods.				$N = 36.3$ periods.				Average.		Calculated.
$\frac{E}{N}$.	E.	C.	W.	$\frac{W}{N}$.	E.	C.	W.	$\frac{W}{N}$.	E.	C.	W.	$\frac{W}{N}$.	C.	$\frac{W}{N}$.	$\frac{W}{N}$.
.2	40.9	.74	13.4	.066	27.5	.76	10.1	.074					.75	.070	.068
.3	61.4	.88	26.8	.131	51.3	.89	18.9	.137					.885	.134	.131
.4	81.8	1.02	42.5	.208	55.0	1.01	28.9	.210	14.52	.95	7.2	.198	1 015	.209	.207
.5	102.3	1.11	60.1	.294	68.8	1.15	40.4	.294	18.15	1.10	10.3	.284	1.13	.291	.296
.6	122.7	1.29	79.3	.388	82.5	1.28	53.5	.389	21.78	1.24	14.0	.386	1.27	.388	.397
.8					110.0	1.57	83.5	.608	29.04	1.58	22.0	.607	1.575	.608	.628
1.0					137.5	2.08	120.0	.874	36.30	2.08	32.0	.883	2.08	.879	.896
1.2									43.56	3.65	44.0	1.21	3.65	1.21	1.20
1.4									50.82	10.8	60	1.65	10.8	1.65	1.54
1.5									54.45	25	68	1.87	25	1.87	1.72

As seen from this table, to the same $\frac{E}{N}$ corresponds in the different frequencies, the same magnetizing current. This means that:

For the range of frequencies from 36.3 *to* 204.5 *complete periods per second the magnetic characteristic is constant, and independent of the frequency.*

Or in other words, within this range,

Up to 204.5 *complete periods per second, magnetic viscosity does not yet exist,*

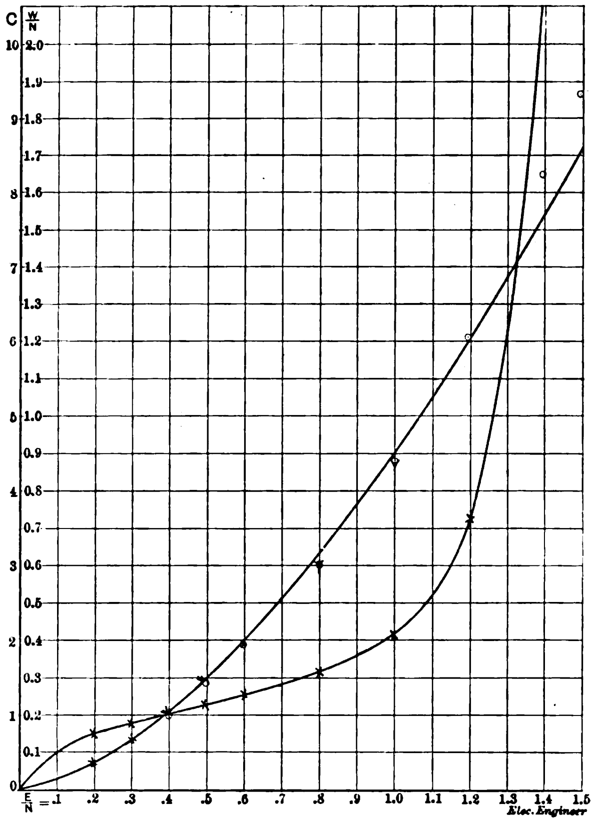


FIG. 2.

but the magnetism follows the M. M. F. as completely as for slow cycles. Eddy-currents, consequently, had no influence on the magnetic characteristic within this range.

To compare the iron losses, in the fourth columns the values $\frac{W}{N} =$ iron loss per cycle, are given. As will be seen, the iron loss per cycle is the same for slow as for high frequency, this means that:

The hysteretic loss per cycle is independent of the frequency, and eddy-currents are practically absent.

Hence, this table proves that:

If eddy or Foucault currents are properly excluded, the magnetization, and the hysteretic loss of a transformer *can, up to* 200 *complete periods per second, be predetermined exactly by calculations based on tests with slow cycles, magnetic viscosity and viscous hysteresis being absent.*

In the last three columns the average values of current, C, and of iron loss per cycle, $\frac{W}{N}$, are given, and the values of $\frac{W}{N}$, calculated by means of the law of 1.6th power, which agree very closely, as seen, with the observed values, except in the last two readings, where, as explained before, the exactness of the method is not sufficient to expect closer agreement.

The values of this table are plotted in Fig. 2, with the magnetization, $\frac{E}{N}$, as abscissæ, and the magnetizing current as ordinates, giving thereby the magnetic characteristic of the transformer iron, in a modified form. The second curve of Fig. 2 is the iron loss per cycle, $\frac{W}{N}$, as a function of the magnetization, $\frac{E}{N}$. By means of these observed curves, we are enabled now to determine the behavior of this transformer under any conditions of load and frequency.

A WEATHER TEST OF TRANSFORMERS.

The present extremely severe winter has subjected all outdoor electrical work to a very searching test, and the illustration shown herewith is one striking example of the ordeals that apparatus deserving of better treatment has to endure. Our vignette, made directly from a photograph taken on the spot, exemplifies pretty clearly what will happen sometimes when we are compelled to hang our transformers where Macbeth hung his banners—"on the outer walls." To sustain such an extra burden of ice and snow a converter and its wires need be very securely fastened, and even then if something gave way it would scarcely be the transformer's fault. As to the improvement in safety and insulation likely to result from such an exposure, perhaps the less said the better. There is some consolation in the fact that the dry ice has saving virtues, but as ice has an unfortunate tendency to get wet and stay so as long as its bank account holds out, it is evident that the conditions, as a general thing, become very unfavorable. The transformer shown in the cut is of Westinghouse make, and that it stands such abuse speaks volumes in its favor. Yet, after all, it does seem unreasonable to place apparatus under such a stress when it would be in every way safer in a dry cellar.

A WIRE GAUGE CHART FOR DETERMINING THE AMPERE TURNS ON SHUNT MAGNETS.

BY

Wm. R. C. Corson.

The accompanying chart as its title implies, is designed for the the purpose of determining the ampere turns obtainable from the different sizes of wire under given conditions of length, of turn and drop in voltage between the terminals of a magnet coil. It has proved of much advantage to the writer in the designing of dynamo fields, as from it the engineer may see at a glance the size and amount of wire necessary for a given machine and thus have a basis for laying out the dimensions involved. The chart also serves as an approximate check for more accurate calculations. Brown and Sharpe's wire gauge numbers have been used, but, as the scale is laid out on a system of which the circular mil is the unit, any other gauge numbers may readily be supplied.

From the chart may be determined :—

1. The ampere turns of a given size of wire at a given average, length of turn and a given voltage and conversely.
2. The size of wire that must be used in order to obtain a desired M. M. F. of a given number of ampere turns, at a given length of turn and given voltage.
3. The weight of wire that must be used in order that no more than a safe current shall flow through the coil.

To obtain the first result, find the number of the wire to be used on one of the horizontal lines to the right, noting whether it be the 1st, 2d, 3d, or 4th line. From this wire number, follow vertically upward to the heavy diagonal line marked "ampere turn line," thence across to the left to the diagonal corresponding to the length of a turn, then down to the lower left hand quadrant to the diagonal of proper voltage, and again to the right to the vertical ampere turn scale. The reading on this scale must be multiplied by 10, 100, 1,000 or 10,000 according as the wire numbered is in the 1st 2d, 3d or 4th line.

The following examples will show clearly the method of using the chart.

1. To find the ampere turns obtained by using No. 21 wire on a 220 volt field at an average length of turn of three feet.

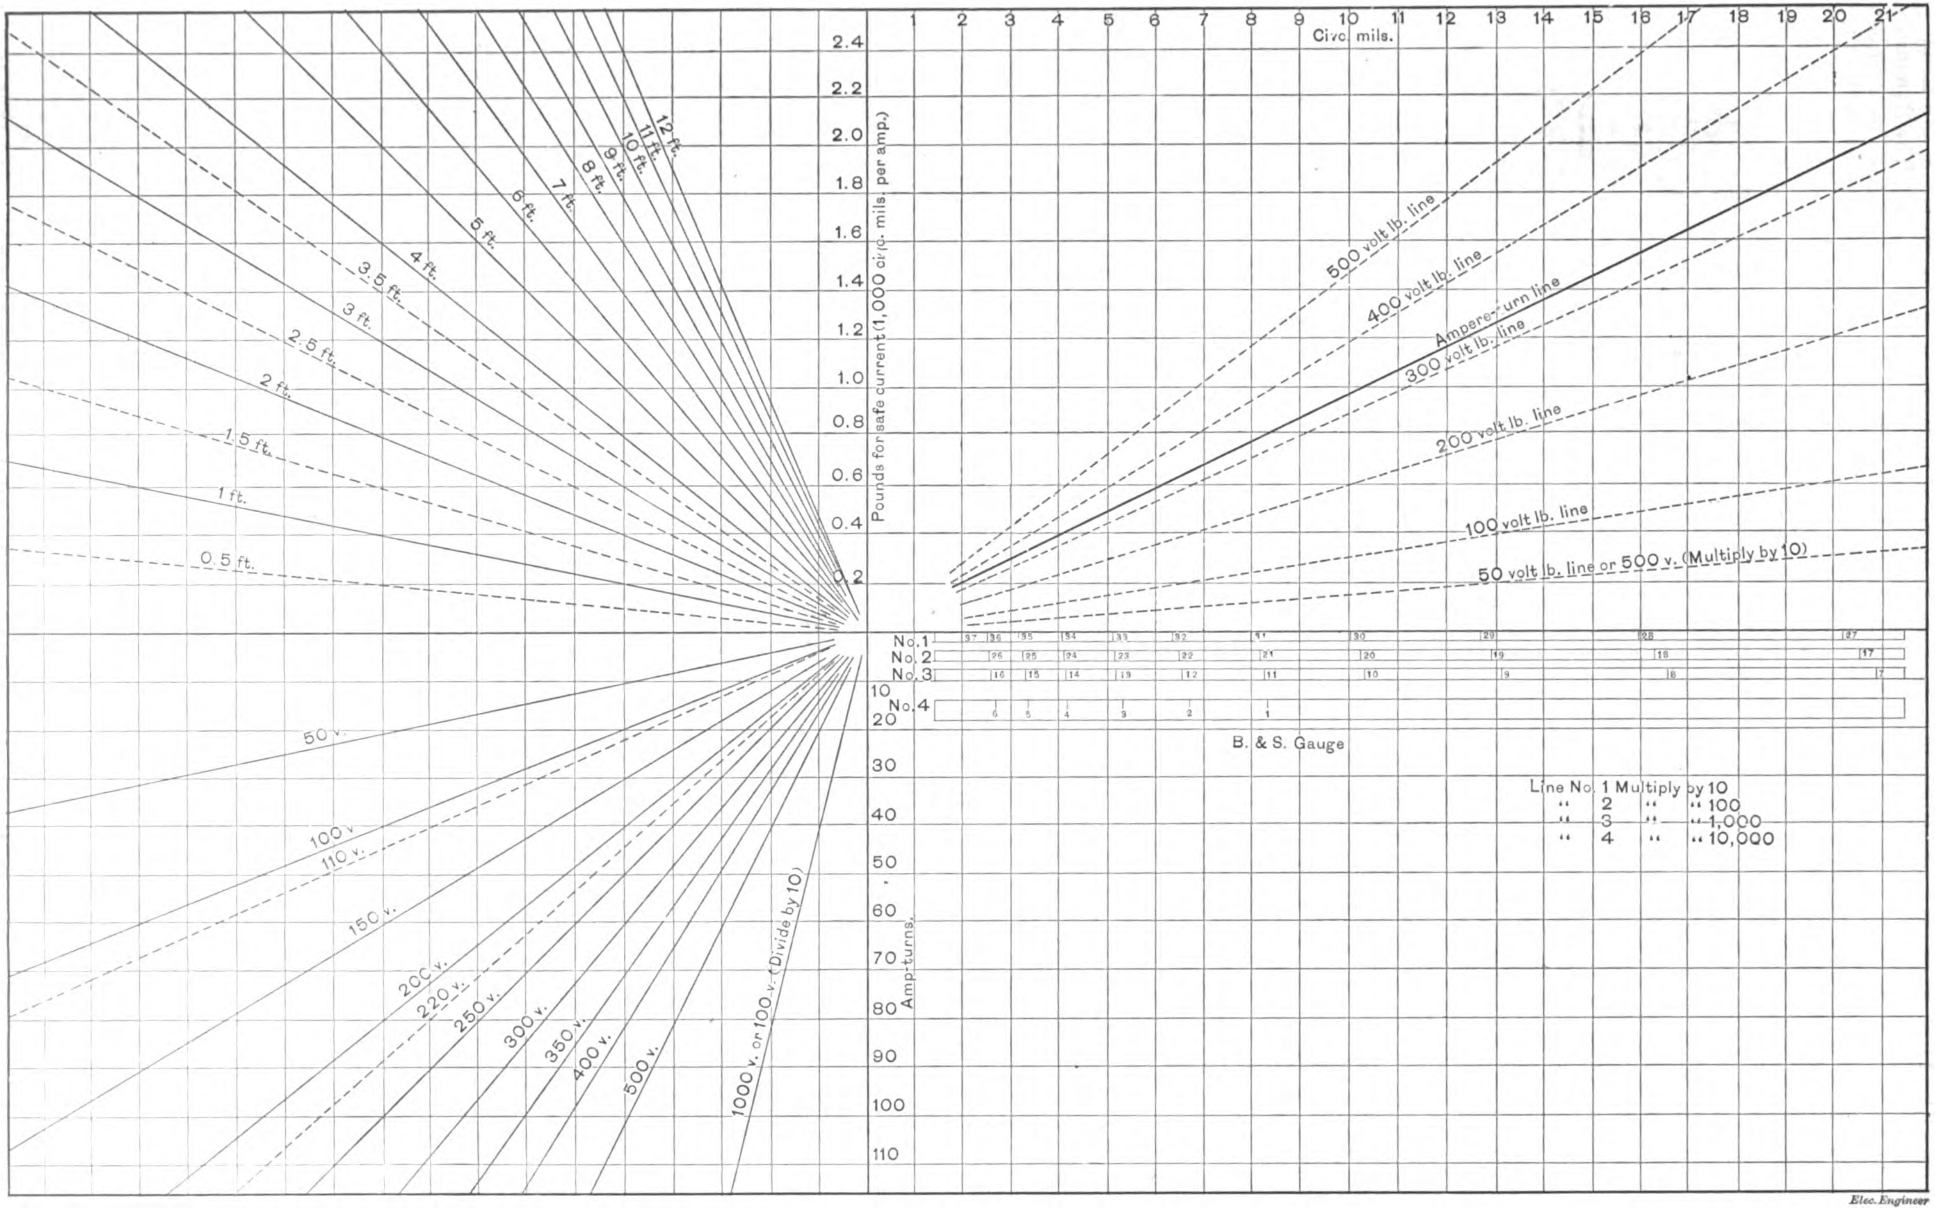
We find No. 21 wire on the line No. 2 and follow up the vertical line to the heavy "ampere-turn line ;" then across to the left to the 3-foot line ; down to the 220 volt diagonal ; and to the right again to a point on the "ampere-turns" scale which in this case reads 58. But we found No. 21 wire on the line marked No. 2 ; therefore we multiply 58 by 100 and obtain as our result 5,800 ampere-turns.

2. The converse of this problem is accomplished by a mere retracing of our steps. Starting from the given number on the vertical "ampere-turns" scale, and remembering the power of ten by which we multiply the scale reading to give this number, we trace to the left proper volt line ; then up to the diagonal corresponding to length of turn ; across to the heavy "ampere-turn line," and down to the B. & S. numbers. Here we find the proper line from the power of ten used in multiplaying at the start.

Example: To find the size of wire neccessary to obtain 40,000 ampere-turns at a pressure of 500 volts, and at an average length of turn of 5 feet.

Starting from point 40, to 500 volts, to the 5-foot line, to the ampere-turn diagonal brings us down to a point which might read 34, 24, 14, or 4. But we multiplied by 1,000 at the start, in order that the scale reading be 40,000 instead of 40. This shows us that the number of wire desired is in the line No. 3 and is therefore No. 14.

3. To find the weight of wire necessary to have 1,000



Wire Gauge Chart for Determining the Ampere Turns on Shunt Magnets.

circular mils per ampere of current, start from the number of the wire and follow up to dotted diagonal reading the proper voltage; then to the left to the vertical scale marked, "Pounds for Safe Current." This scale reading, like the others, must be multiplied by a power of ten corresponding with the line in which the wire number was found.

Thus, to find the weight of wire neccessary in the last example taken, from No. 14 follow up to the dotted diagonal marked 500 volts; then across to scale, reading 0.59. This multipled by 1,000 gives 590 lbs. as the weight necessary. Other sections of conductor per ampere may be determined by direct proportion.

The weights given are for bare copper wire, and resistances for pure copper at 75 degrees Fahrenheit.

THE SCOTT-SISLING SYSTEM FOR ACCUMULATOR INSTALLATIONS.

BY

W. B. Sisling.

Nearly eighteen months ago this arrangement was described in The Electrical Engineer with the aid of a rough diagram. Since then its use has considerably extended and its details have been perfected. Fig. 3 shows the switchboard, which enables a compound dynamo to be run in parallel with accumulators without risk of reversal.

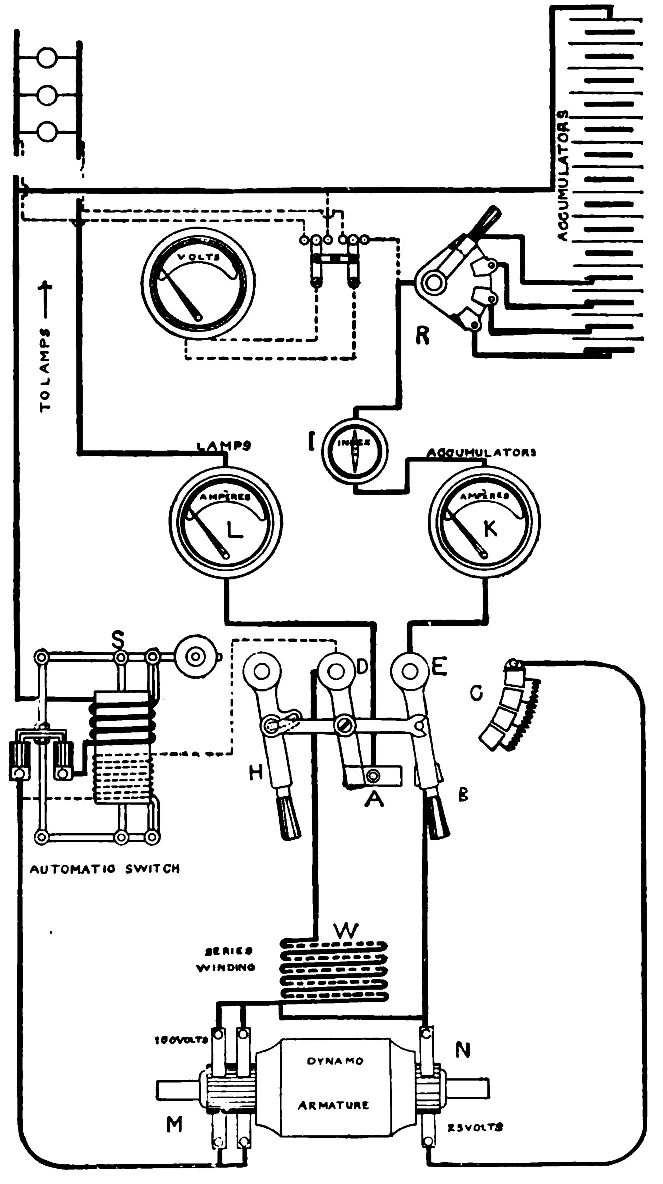


Fig. 1.—Diagram of Connections.

A is connected to lamp main through the ammeter L. B is a contact for running cells in parallel with dynamo. C is the contact for charging cells. It is divided into sections connected by resistances. D is the dynamo switch. H is the handle for closing dynamo switch. E is the accumulator switch connected to cells through the current index I, and the ammeter K. R is the regulating switch for adjusting the number of cells in circuit. W represents the series winding of dynamo.

The dynamo is a special one, and is shown in Fig. 2. It has an extra commutator arranged to give the additional E. M. F. required for charging accumulators. The dynamo can, therefore, be driven at constant speed (as from mill shafting or from an engine with a good governor) and will supply steady voltage to the lamps, although it is at the same time charging accumulators and subject to fluctuations in the number of lamps alight. The charging of the accumulators can be regulated in such a way as to partially balance these fluctuations, thus keeping the load approximately steady and securing economical conditions of running. The arrangement thus shortens the working hours of the plant by avoiding the necessity for running specially to charge the accumulators during the daytime.

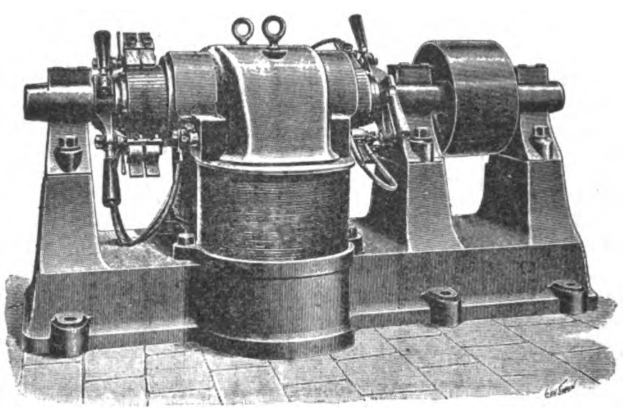

Fig. 2.—Special Dynamo for Charging Accumulators.

The battery assists the dynamo when necessary at full load, and is always in readiness to do this without alteration of switches when it is not being charged. Only one battery switch is required, as it is always in circuit, and thus answers for both charging and discharging.

The whole arrangement of connections is clearly shown in Fig. 1, from which the working may be traced.

The plant is made by Messrs. Laurence, Scott & Co., Ltd., of Norwich, England, and seems to hit the mark for those installations which have to be operated by comparatively unskilled men, as its manipulation is very straightforward.

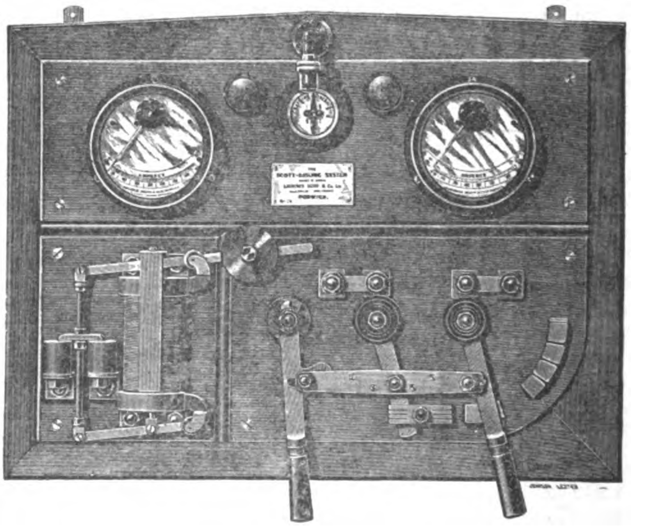

Fig. 3.—Switchboard for Charging Accumulators.

"TAKING THE DOUGHNUT."

A New York electrical engineer and expert writes: "I take pleasure in renewing my subscription to The Electrical Engineer for which I enclose $3. It strikes me that The Electrical Engineer is taking the doughnut away from them all."

VOL. XV. NEW YORK, MARCH 1, 1893. No. 252.

CONVENTION TOPICS.

THE meeting of the National Electric Light Association at St. Louis, this week, is an event of unusual importance, and will without doubt be well attended. It is some time since the Association went so far South and West, and in the interval not only has the electric light and power industry developed greatly, but the growth in the region supplied from St. Louis has been very rapid and extensive. The electrical facilities of the city are second to none in the Union, and this fact alone would make the visit a pleasant and profitable one to active, inquiring men, anxious to discover the best practice in the art up to date. But St. Louis is a city of generous and hospitable proclivities, and has determined that on this occasion as on every other, her guests and those of President Ayer, shall find themselves thoroughly at home.

In addition to the attractions of the convention city, are those of the programme furnished by Secretary Porter, who has made a most judicious selection of authors and topics and who has rallied to his support some of the brightest men in the profession. Further éclat is given by the appearance of Mr. Nikola Tesla, who too rarely honors the platform and whose remarkable researches have not been publicly illustrated in this country for nearly two years.

In Mr. Tesla's work is the rich promise of many things yet to be, and when we consider how quickly his ideas and inventions in the field of alternating current motors have fructified, we may fairly be sanguine as to the other problems in light and heat that he has set out to solve. It is such leaders as he that guide ever into Canaans flowing with the milk and honey of new opportunities, and electricity has not yet wanted for such men.

Meantime, the members of the convention will doubtless discuss in private, if not in public, the situation that has been constituted so curiously and anomalously the last year by the consolidation of old antagonistic parent companies and the validation of fundamental patents under their control. The electric lighting industry is still an open one, yet it would be worse than foolish to say that it is not better to be within the protection of such patents than outside it. The very object of patents is to create new property and to encourage investment by the stability and shelter afforded. Shall it be that men like Edison, Elihu Thomson, Brush, and scores of others have worked in vain, and that money has been wasted in perfecting and introducing their inventions? If so, the inventive genius of the age will forsake electricity very quickly for other fields of labor.

That is one view of the situation—a sound and fair one—but not complete. To-day, a single lamp patent affects the largest department of electrical activity in lighting and current distribution. That patent is a mainstay of interests that but yesterday were fighting it, and stands in the name of an inventor who opposed with all the weight and force of his tremendous personality the use of the alternating current and apparatus by which a greater extension has been given to the incandescent art than it ever enjoyed before. Outside of that patent, and outside those interests, money, time and genius have been spent like water in building up the art, in devising improvements, in refining apparatus, in cheapening and simplifying details. It is therefore the sense of the electrical industry and profession, as it should be and perhaps is, the dictate of the law, that one patent shall not enjoy all the reward due to hundreds of others, and that one interest shall not preëmpt for itself all the profit that the art as a whole is entitled to as its return for the benefit conferred on society. The man who invents type, it is argued, should not usurp the gains of the man who perfects paper, nor shall these together crowd out the men who have perfected the printing press, the book binding machine and the best printer's ink. But there is a deep-seated fear in many quarters that just such a selfish policy is to be attempted in the electric lighting and power field.

For ourselves, we refuse to believe that such a policy will be tried, or if tried, will prevail. Our firm conviction is that the best interests of the controling companies, the best interests of the local companies and the best interests of the consuming, purchasing public, the ultimate bearer of the tax, demand a broad, liberal, comprehensive policy, which sees its triumph not in a restriction of the field to a few, but in a stimulation of every thought, agency and activity that can help to extend the art. For the adoption and maintenance of this policy we shall contend, believing as we do that it will carry with it general prosperity and the success of all the principles that the National Electric Light Association has striven for.

The Westinghouse Lamp.

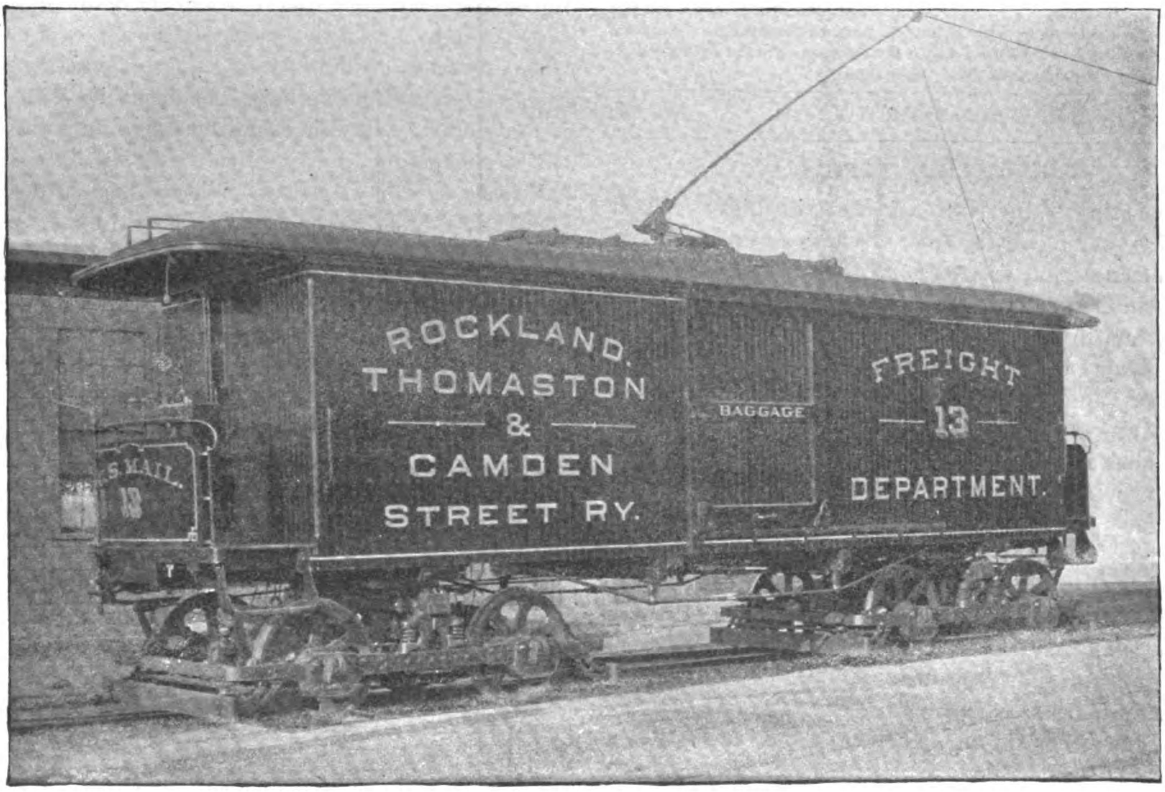
The opinion of the United States Circuit Court at Pittsburgh—of which the main portion is printed in our Legal Notes—in the matter of the new Westinghouse lamps, may be regarded as in some degree a victory for the Westinghouse Company; for while it grants the motion of the Edison Company to dismiss the rule to show cause why the standing injunction should not be modified or construed so as to free the new lamp, yet the Court commends the spirit in which the Westinghouse Company approached it, and leaves them free to go on with the new lamp until a final hearing in the pending suit.

ELECTRIC RAILWAY DEPARTMENT.

ELECTRIC FREIGHTING AT THOMASTON, ME.

The benefits conferred upon neighboring towns by an electrical interurban passenger railway have become so universally acknowledged, that the adaptation of the street railway motor to freight service seems only a natural consequence. There are, however, but few examples of this, and it is a pleasure to us to describe such an adaptation in the hope that the good example may be followed.

Through the towns of Rockport and Camden, Me., runs the Rockland, Thomaston and Camden Street Railway, at present 9½ miles in length, with a probable extention of three miles to the town of Thomaston. The Knox and Lincoln Road, an extention of the Maine Central Railroad runs as far as Rockland only. At that point the country assumes markedly hilly characteristics and offers considerable difficulty to the extension of the steam road to the seaport towns of Rockport and Camden. An electric road was therefore laid down, with extremely successful results; fulfilling in every particular the best provisions of the steam roads.



Electric Freight and Motor Car, Rockland, Thomaston & Camden (Me.) Street Railway.

So successful, indeed, has been the passenger service, that the project of establishing a freight service seemed to the Street Railway Company excellent, and the experiment was decided upon. An order was placed with the General Electric Company for one locomotive freight car, which we illustrate. The car resembles those in use on steam railroads. It is provided with sliding doors in the centre of each side and smaller ones at both ends to give access to the platforms. It is 25 feet long, 7 feet wide, and 7 feet high and has, at each end, a platform 30 inches wide, protected by the overhang of the car, and having a dashboard in front, similar to those in use on the street cars. The platform is fitted with brake, controller and reversing switch, foot and starting gongs and a single lamp. The interior is illuminated by three lamps in series with the platform lamps.

The body of the car is mounted on two No. 29 Bemis steel trucks with wheels to the standard gauge. On each axle is mounted a General Electric W. P. 50 motor, making four motors in all and current is taken by means of the ordinary overhead trolley. The car weighs a little over 15 tons and has a carrying capacity of 20,000 lbs. It is intended to use this car as a locomotive, pulling an ordinary freight car as a trailer, which will add about 9,000 lbs. to the weight to be propelled by the motors.

The car is guaranteed to carry at least 20,000 lbs. up an 8 per cent grade at a maximum speed of about 5 miles an hour, with a maximum on the level of about 10 or 12. Of course if this can be exceeded, our intimate knowledge of the motor-man in general, and of his aspirations, leads us to believe that it will. He is sure to "let her out." The car itself is a handsome structure painted dark red, with white lettering, and having nickeled and black trimmings.

The road itself is built in a most substantial and workmanlike manner, with 50 lb. T rails laid on sleepers two feet between centres, the idea of a freight service having been contemplated from the outset.

One of the most important facts in connection with this road is that it has secured the contract to carry the U. S. mails between the towns through, and to, which it runs. This service has been undertaken at a merely nominal figure, but the benefits the Company are likely to derive from the right of way and federal protection which connection with the post office gives them will amply repay them for any loss they may incur in the actual transport of the mails.

ANOTHER LARGE TROLLEY SCHEME FOR NEW JERSEY.

A CORPORATION with small capital and big capitalists behind it was incorporated by the Legislature at Albany, on February 16, "for the purpose of constructing railroads and furnishing power to railroads in New York City." The capital is $5,500, and among the directors are President John A. McCall of the New York Life Insurance Company, Henry B Hyde, Gen. Louis Fitzgerald, and Superintendent F. K. Hain of the elevated road. President McCall states that the company has nothing to do with the elevated road or with the present Metropolitan Traction Company. "It concerns one electric surface road in New Jersey and two horse railroads in this city," he added. "The electric road is in Paterson, N. J.. and consists of the Grand Street, Paterson, Central and Little Falls branches. This road was organized some time ago with a capital of $200,000, which was all paid in. It has no debts, and has been quite prosperous ever since it started. The two horse railroads in question noted the success of the Paterson electric street railway, and made overtures looking towards their purchase by it. The directors of the Paterson road desired to accept the offer of these two horse railroads, but found that their charter would not permit them to make the purchase. For this reason it was decided to organize the New York Traction Company, which should have the power both to buy both the Paterson road and the two horse railroads. The names of these latter roads I am not at liberty to mention, because the negotiations between them and the Traction Company are not yet completed. The smallness of the capital is on account of the tax laws. As we absorb the companies referred to we can increase our capital. It is our intention to ask the officials of Bergen County to grant us a franchise for laying a double-track trolley road from Paterson to the Hackensack River and across the Secaucus bridge into Hudson City and Hoboken, the authorities of which will then be asked to permit the extension of the road to the Hoboken ferry on the Hudson River. Something like fifty miles of track will be laid at an estimated cost of about $500,000. If we succeed in buying the two horse railroads, we shall equip them with the trolley. We do not intend to extend our purchases beyond the two roads in question."

The directors of the new company are: ex-State Senator Charles H. Russell and Charles Currie of Brooklyn, James A. Morrissy and F. C. VanDyke of Paterson, N. J.; Charles A. Johnson of Johnson, Kenny & Co., Raymond C. Johnson, Thomas D. Jordan, George V. Turner, W. H. McIntyre, Superintendent Hain and President McCall.

A WIDE-REACHING TROLLEY CONSOLIDATION IN NEW ENGLAND.

A NUMBER of street railways in Boston, New Haven, Providence, Springfield, and other cities in New England have been consolidated in one company under the name of the New England Street Railway Company. The certificate of incorporation, which was filed February 16 in the office of the Secretary of State of New Jersey, at Trenton, N. J., provides for a capital of $5,000,000, which may be increased to $50,000,000. The directors of the company, including many prominent New England financiers, are as follows: John R. Bullard, president of the Dedham (Mass) Savings Bank and the Dedham National Bank; James C. Elmo, president of the Shoe and Leather National Bank, of Boston; Col. John H. Cunningham, president of the Winnisimmet National Bank, of Chelsea, Mass.; W. B. Ferguson, president of the Gloucester Street Railway Company, Gloucester, Mass.; Hon. William H. Leonard, vice-president of the North National Bank of Boston; Dr. A. F. Mason, capitalist; Maj. A. C. Pond, president of the New Haven and West Haven Street Railway Company; A. R. Mitchell, vice-president of New England Trust Company, Boston; Thomas T. Robinson, treasurer of the West Leicester and Spencer Street Railway Company, Boston; James B. Dill, of Dill, Chandler & Seymour, New York, the counsel for the company. The charter obtained by the company is one of the broadest charters ever secured under the General Act in the State of New Jersey, and gives the company even more latitude than the now famous charter of the North American Company, which was organized in the same State under the same act. The Corporation Trust Company, of New Jersey, is designated as the trustee of the company in New Jersey, and the New England Trust Company in Boston as the trustee in Boston.

TROLLEY CARS HAVE RIGHT OF WAY.

THE supreme court of Pennsylvania, through Justice McCollum, in the case of Winter against the Federal Street and Pleasant Valley Passenger Railway Company of Pittsburgh, gave on January 31 an opinion which will probably greatly affect street railway matters in this state. The defendant corporation is an electric railway and is operated by means of the trolley system. The plaintiff was the owner of a truck and two horses. He was employed in putting a safe into a building and his horses stood in a position to impede the progress of the cars. Several times he moved his horses in order to let the electric cars pass, but finally refused to move, contending that he had a right to the thoroughfare for a length of time sufficient to finish his work. One of the cars came along and, running into his horses, inflicted such injuries that he was compelled to kill them. Suit was begun in the common pleas courts of Allegheny county and a verdict secured for damages just sufficient to cover his loss. The defendant company applied for a new trial but was overruled by the Judge. The supreme court reversed the decision or the court below. If the cause given had been contributory negligence there would be no cause for general complaint, but in his opinion, Justice McCollum, in order to strengthen the contributory negligence reason, said: "In these days of rapid transit, by means of the cable and trolley systems of car propulsion, property-holders along the line of the route and citizens generally must be given to understand that that there must be an abridgment of their uses of the street. To use them now as in the days of car horses would be impracticable."

The opinion is a long one and is devoted to emphasizing the rights of the cable and trolley rapid-transit companies to the right of thorougfares.

THE TROLLEY SYSTEM IN BROOKLYN.

THE shareholders of the Brooklyn City railroad have ratified the lease of that road to the Brooklyn Heights Company. Legal proceedings to prevent the lease from going into effect were also begun by James C. Church on behalf of Joseph B. Markey, a stockholder in the road.

This plan of leasing the road has been under consideration for several months, and president Lewis and a syndicate have been buying the stock of the Brooklyn City Road for nearly a year. Their purchases recently sent the market price up to $300 a share. The terms of the lease are that a dividend of 10 per cent. is to be guaranteed on the old Brooklyn City stock, but Mr. Markey alleges that, with the introduction of the trolley system the road can earn at least 18 or 20 per cent. and that the men on the inside are going to divert that excess of profit to the leasing company, which they own.

The Brooklyn Heights Company has hitherto been a small concern that operates the short cable road through Montague Street, to the Wall Street Ferry. It has a capital of only $200,000, and the stock had no market value until a few months ago, when president Lewis and his friends started in to get control and bid it up to $75, a share.

The capital of the Brooklyn City Road is $12,000,000, and it is upon this capital that the guaranteed dividend of ten per cent. is to be paid.

FINANCES OF THE LONDON UNDERGROUND ELECTRIC ROAD.

THE financial result of the working of the City and South London Railway for the half-year ended December 31st last, shows an improvement upon that arrived at in the corresponding period of 1891. During the last six months of 1892, the passenger receipts amounted in round figures to £22,000, as against £19,800 for the last six months of 1891. On the other hand, the corresponding total expenses were in round figures £15,390 and £15,516; the outcome being a dividend at the rate of ⅝ths per cent. per annum to the ordinary shareholders. Since the opening of the line some two years ago, more than 11⅛ million passengers have been carried; and the figure for the last half of 1892 exhibits a 17 per cent. increase upon that for the corresponding period, the increase in train mileage being nearly 14 per cent. The locomotive and generating expenses per train mile run are now down to 7.1d.

A COMBINATION PLANT FOR GRAHAM, VA.

MR. WALTER GRAHAM of Graham, Va., has secured the franchises for the towns of Graham, Va., and Bluefield, W. Va., for electric lighting and electric railway. It is the intention to connect these places, which are about two miles apart, by an electric street railway, and to light both towns with incandescent and arc lights, all to be done from one central power house. A company has been formed and capital is being invited to invest in the enterprise. The situation is but one of many in which combination plants should prove very profitable.

RADIAL CARS IN BOSTON.

THE WEST END STREET RAILWAY COMPANY of Boston is the defendant in a suit begun in the United States Circuit Court in that city, in which the damages claimed are $1,500,000. The plaintiff is the Robinson Radial Car Truck Company, and the suit is based on alleged infringement of letters patent owned by the plaintiff, covering the manufacture, use and sale of electric radial trucks.

WORLD'S FAIR DEPARTMENT.

DETAIL ELECTRICAL WORK ON FAIR GROUNDS AND BUILDINGS.

THE long spell of intensely cold weather that has been experienced universally throughout the country has delayed nearly every branch of work at the Exposition grounds, notwithstanding the strenuous efforts that have been made to keep the work moving. The ground is frozen to a depth of two feet and all excavating is done at great expense. The foundations for several new buildings have recently been laid, the frozen earth being blasted out with dynamite as if it were solid rock.

In laying ducts for electric wires a trench is dug about twenty inches wide and the same in depth. Most of this work was done last fall before the cold weather set in, but in some places it could not be reached in time and the ground froze. Now a man can dig about three linear feet of trench of this size (*i. e.* 20 inches wide and deep) in a day. In fact it has been necessary to stop all work on the outside of the buildings and in all exposed places. Even inside the men work at great disadvantage because of having to wrap themselves up so heavily to keep warm, and frozen hands, noses and ears are very common. In the annexes to the Gallery of Fine Arts the wiremen follow closely on the heels of the carpenters and wires are strung on roof timbers as soon as they are in place, the men working in the snow as it drifts into the yet unroofed buildings. Owing to these difficulties there is not much to record in the way of new developements in the electrical work.

MAIN ENTRANCE TO ELECTRICITY BUILDING.

After one of the heavy rainfalls that occurred early in the winter a force of men were sent out by the Landscape department to dig trenches to turn the water that had accumulated in the lower spots in the roads into the sewers. These men, laboring under the delusion that everything in the nature of a hole in the ground was a sewer, carefully unscrewed the covers from the electric manholes and turned the water into them. A long period of cold weather followed, and the ducts being only 18 inches below the surface, the water in them froze solid. When the work of drawing in the cables was begun a few days ago it was found that there was no hole to draw them into, a cake of ice having taken its place.

As it was not possible to delay the work of drawing in the wires until the weather was warm enough to thaw the ice, various schemes were suggested to overcome the difficulty, and a jet of steam was decided upon as being the most efficient and convenient.

The next question was how to get a supply of steam for the purpose in such parts of the grounds as were not near a boiler. At last a novel idea was hit upon. Among the goods and effects of the Exposition are several small steam rollers used for rolling paths. These weigh about two tons each. It was proposed that one of these be used to supply steam to thaw the ice from the ducts. The snow being deep and the road ways covered with ice, it was found that the roller would not "work its own passage," so it has been mounted upon a sled and four horses drag it from place to place as its services are required. The scheme is quite successful and the most refractory length of frozen duct yields in a few minutes. A length of rubber hose is run from the blow-off cock of the boiler into the duct and as soon as one length between two manholes is thawed out the manhole is bridged with a piece of pipe and another length thawed without moving the roller. So successful has this proved that a large 10-ton roller has been fitted with ice creepers in the shape of large spikes fastened on the wheels and the work is greatly hastened by its aid. The operation of drawing in cables is progressing rapidly and it will not be long before the temporary poles and wires disappear. The interior wiring for arc lights has been delayed somewhat because the aisles could not be laid out until the exhibit space was allotted. This has been finished in nearly all the buildings and the work of wiring is now going rapidly forward.

Several hundred of the arc lamp posts are now in place and more are continually arriving. Before they are set on the foundations the latter are carefully shimmed to correspond to the grade line of the road. All posts are inspected as they are unloaded from the cars, and the imperfect ones rejected.

The work of installing the electrical machinery in the great central station in Machinery Hall has begun. Two 4,000-light Westinghouse alternators have been placed upon their foundations within the past week and are now ready to run as soon as power is to be had. They are belted direct, each to a 400 h. p. Westinghouse compound engine. The engines are set up and only need steam connections to make them ready for duty. The temporary power plant is loaded beyond its normal capacity and as the demands for additional lights are constantly increasing, the work on the permanent plant is being pushed as rapidly as possible in order to relieve the overworked boilers of the temporary plant. Two of the 10,000-light machines have been shipped from Pittsburgh and will soon be in position on the foundations prepared for them. One of these machines is to be connected directly to a 1,000 h. p. Westinghouse compound engine. The other is to be driven by the 2,000 h. p. Allis Corliss engine by means of a belt six feet in width. The pulley for the dynamo shaft is nine feet in diameter and six feet in width of face. Nine Fort Wayne, nine Standard, and several Brush arc machines are being installed, though the engines which are to drive them are not yet erected.

The work of handling these heavy pieces of machinery is made easy by the great electric travelling cranes, three of which extend the entire length of the building. A machine is brought into the building on a car. The crane picks it up and carries it as near as possible to where it is to stand. It is then put on rollers and a stationary motor and drum draw it upon its foundation. It is hoped that the greater part of the load now carried by the temporary power plant can be transferred to the permanent plant by the middle of March.

The contract has been awarded for the iron work for the mammoth switchboard, and the work of erection has already begun. The marble tablets and instruments have been shipped from Pittsburgh and will soon be in place.

L. W. C.

FELIX STARKENBERG.

FELIX STARKENBERG, the Swedish inventor, who, two years ago, exhibited at the Battery a wave motor by means of which he proposed to generate electricity for light and power, died recently in Brooklyn. Failing to interest capitalists in his plan, he had turned his attention to a number of other novel mechanical devices, the last of which was just about to be introduced to the public when he died. It is understood that he leaves a large family with but scanty means of support.

SOMETHING NEW.

THE Columbus, S. C., *Register* states that "Trolley poles for the electric street railroad are being erected on Laurel street."

MISCELLANEOUS.

ELECTRIC POWER IN MILLS AND FACTORIES.

WHILE the employment of electric motors for driving machinery is common enough in isolated cases, where the electric motor takes the place of a small steam, gas or water motor, the advantages of equipping a large factory or mill entirely with electric power are only beginning to be appreciated by those interested in such works. Even now the plants so equipped, though small as compared with the number in which isolated motors are employed, have proven in actual practice the reliability and economy of this system of power transmission in factories, and a brief enumeration of its advantages will show beyond cavil, its superiority over all other methods.

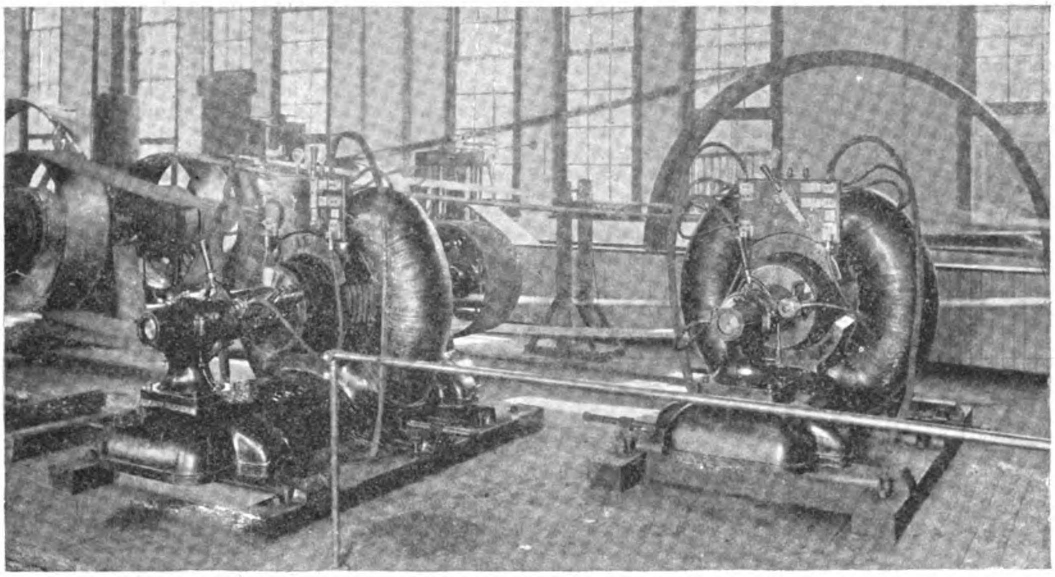


FIG. 1.—CENTRAL C. & C. ELECTRIC POWER PLANT, FRASER & CHALMERS, CHICAGO, ILL.

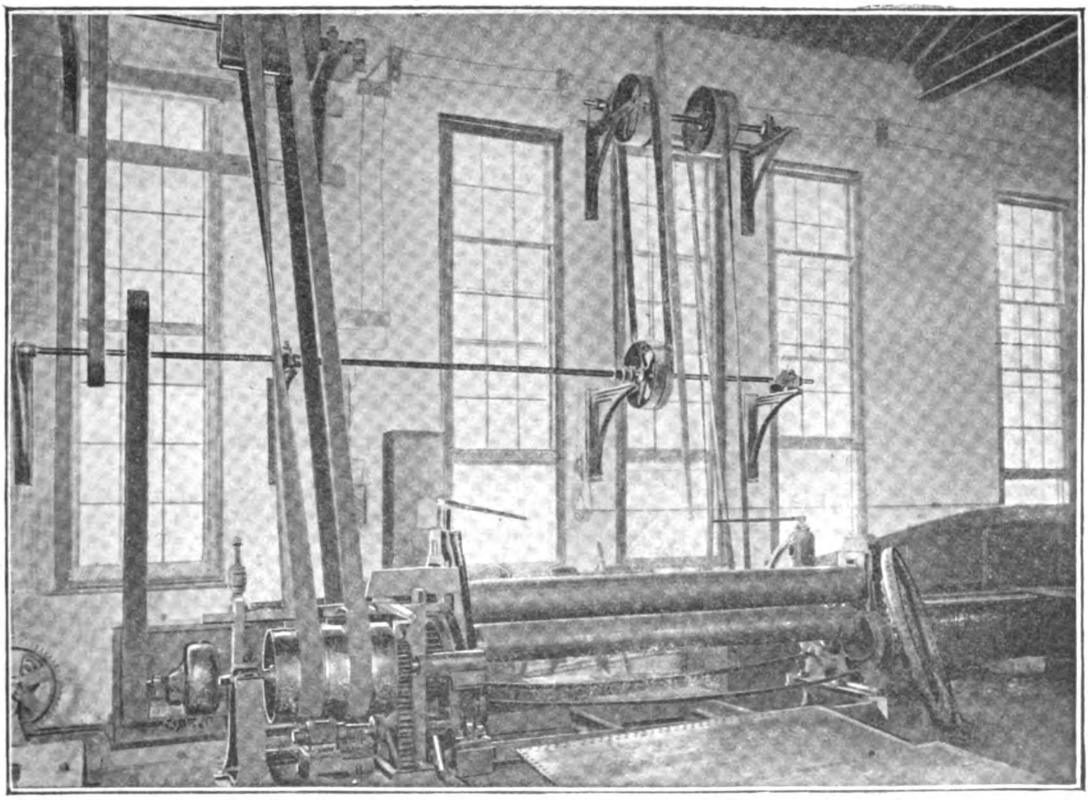

FIG. 2.—10-FOOT BOILER PLATE ROLL, OPERATED BY C. & C. MOTOR, FRASER & CHALMERS, CHICAGO.

The general practice in mill and factory power transmission involves the use of belting, shafting and gearing which must be kept in continuous motion whether 1 or 500 horse power is being actually consumed by the machines driven; it makes no difference whether one lathe or loom, or fifty, are in motion, the shafting must be always in operation. Now it has been proven by oft-repeated and reliable tests that from 25 to 50 per cent., of the entire power generated and consumed in factories and mills is absorbed in merely keeping the shafting and belting in motion. In other words, on this old plan it would take anywhere from 100 to 250 h. p. alone to keep the shafting in motion in a so-called 500 h. p. installation.

It is a matter of general observation that the machines in manufacturing establishments are not operated continuously, but on the contrary, are started and stopped at intervals varying from a few seconds to several minutes; and again, the very nature of some machines is such as to make the draft of power intermittent. Take for example a planer; here the full power may be required for 30 seconds at the cutting stroke, while the return stroke of the platen is accomplished in 10 seconds with an expenditure of but a small fraction of the power previously used. Under the old method of belting, the engine would not, as it were, feel this change, for the reason that it would take too long for so small a change in the entire power to travel back through counter, main and jack shaft to the engine, and affect the cut-off.

But with electric transmission the case is entirely different. Here all machines are driven individually by motors deriving current from a dynamo driven directly from the engine. Hence, the instant a machine stops,—or as in the case of a planer, its power consumption is reduced,—the current required by the motor is correspondingly reduced; this reduction of current is immediately felt by the generating dynamo and the cut-off of the engine in turn at once operates to reduce the steam consumption. The saving in steam naturally means a corresponding saving in the coal pile. Another point worth noting is that whereas the loss in shafting is practically constant for all loads, with electricity the loss in the wiring decreases with light loads. Thus if a circuit is designed for a loss of 1 h. p. when carrying full load the loss will be only about ¼ h. p. at half load.

Among electrical manufacturers who early realized the facts above cited are the C. & C. Electric Motor Co., of this city, who demonstrated their faith in the correctness of the principle involved by equipping their own factory in this manner some years ago. Here five floors, filled with machinery, are operated by motors, a small conduit running up the side-wall carrying the circuits to the various departments, from the dynamo in the basement.

Among the notable plants of this nature recently installed by the C. & C. Co. is that in the enormous works of Messrs. Fraser & Chalmers, manufacturers of mining machinery, engines, boilers, etc., at Chicago. At the present time only a portion of the contemplated works are in operation, the rest being in process of construction. The power house is located away from the main buildings and near the centre of the works, and from here there are run three circuits delivering current with a loss of from 2 to 5 per cent. to the foundry, pattern shop and boiler shop, the only buildings thus far completed. Our engraving, Fig. 1, shows a view in the power house in which are located two C. & C. 80 k. w. standard compound dynamos driven by two Fraser & Chalmers' Corliss engines. These dynamos are designed to deliver current at 250 volts, regulating automatically for all loads, and supply power and incandescent lights for the entire works.

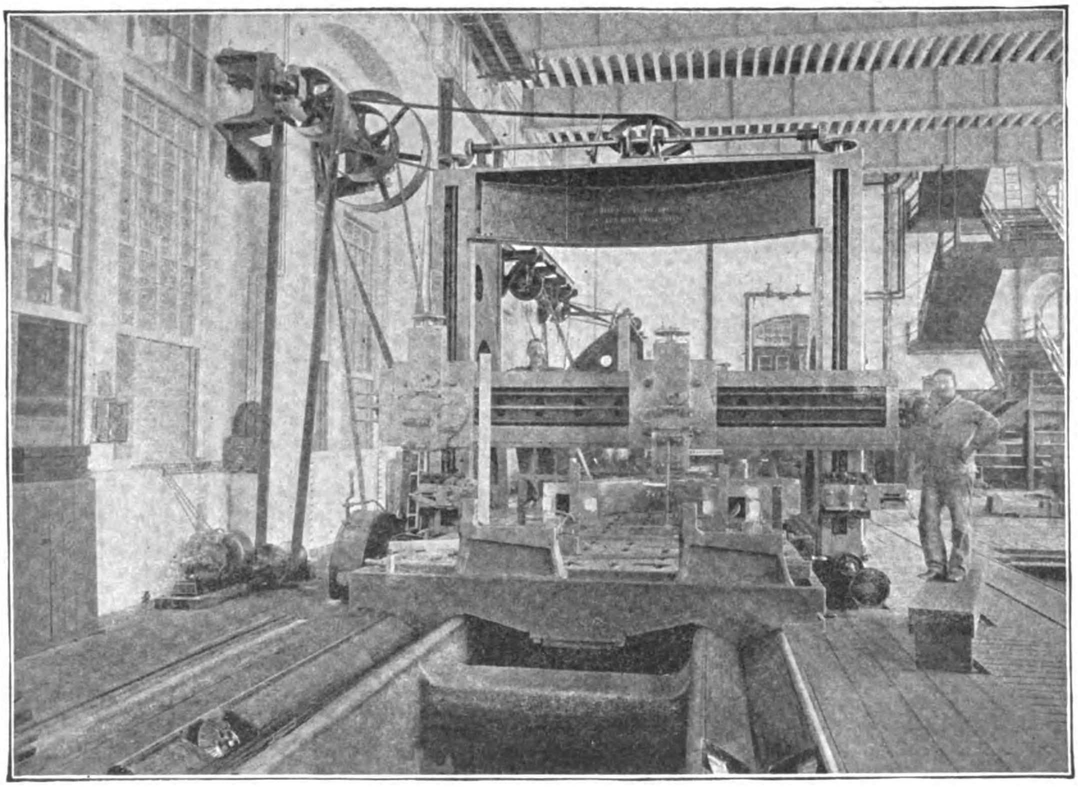

FIG. 3.—10-FOOT PLANER OPERATED BY C. & C. MOTOR, DE LA VERGNE REFRIGERATING MACHINE CO., NEW YORK.

But in addition to these vital points of economy there are others of hardly less importance; thus the cost of renewal and keeping in order of shafting and belting can be reduced to a small fraction by electric distribution. Again, on the score of convenience this method must be conceded to be *facile princeps.* Thus, with electric power any part of the works can be run independently of the rest, the mere throwing of a switch serving to cut off the power; as compared with the operation and cost of clutches required by the old method, the switch is toy-like in its simplicity. Again, by the electric method power may be obtained at any point, however distant, with the greatest facility. This fact is of special importance in factories and shops where portable tools, such as drills, must be applied to heavy work, and which can readily be carried out by the aid of the electric method of transmission.

If to all these advantages we add, that light and power can be had from the circuits; that the power generating station can be placed at a considerable distance from the factory proper, and thus reduce the fire risk, or to take advantage of a waterfall, for instance; that the power consumed by any machine or any number of machines can be readily ascertained by means of a recording wattmeter and that the application of electric power is accompanied by perfect cleanliness,—then it will be admitted that it is only a question of time when this mode of power transmission will be the preferred one in well-designed factories.

In the foundry there is operated a 65 h. p. motor running a No. 6 and a No. 4 Root blower, supplying blast for the cupola furnaces. Here is also a 4,000 lb. Reedy elevator driven by a 20 h. p. motor. For handling heavy castings, moulds, etc., there is a Yale & Towne jib crane worked by two standard C. & C. motors. The hoisting and lowering motor is of 7½ h. p. capacity, working up to 12 h. p. maximum and the trolley motor is of 5 h. p.

The power equipment of the pattern shop consists of a 25 h. p. motor, and a 20 h. p. motor, which run a 24-inch planer, cross cut and rip saws and 2 band saws; also 4 lathes and 1 grind stone. There is also a 15 h. p. motor running an elevator in this department.

The boiler shop contains a great deal of heavy machinery, and the freedom from line shafting and counter belts is noticeable. Most of the machines are divided into groups of 2 or 3 driven by one motor, though in some cases there is a separate motor for each machine. This shop contains the following machinery: One 5 h. p. motor running boiler-plate shear and large upright drill; one 10 h. p. motor running large hand punch, bevel shear, turret lathe and 16-inch shaper; one 10 h. p. motor running slitting shear and large boiler-plate punch; one 5 h. p. motor running boiler-plate punch, shear and small vertical drill; one 10 h. p. motor running 10 foot boiler-plate roll and 20 foot plate planer; one 10 h. p. motor running a Williams, White & Co.'s bulldozer; one 10 h. p. motor running a large bevel shear, upright drill and punch; one

5 h. p. motor running 2 sets of 5 foot sheet iron rolls and automatic sheet iron punch ; one 5 h. p. motor running a No. 1 Root blower supplying draught for forge fires.

Our engraving Fig. 2, gives a view of the 10-foot boiler-plate roll, and shows the method of connecting the motors to their work. The motors throughout the shops are provided with automatic cut-off starting switches, so that when the current is cut off at the main switch-board, each motor is cut off from its circuit. This prevents the possibility of injury to motors from the current being suddenly thrown on them from the power house.

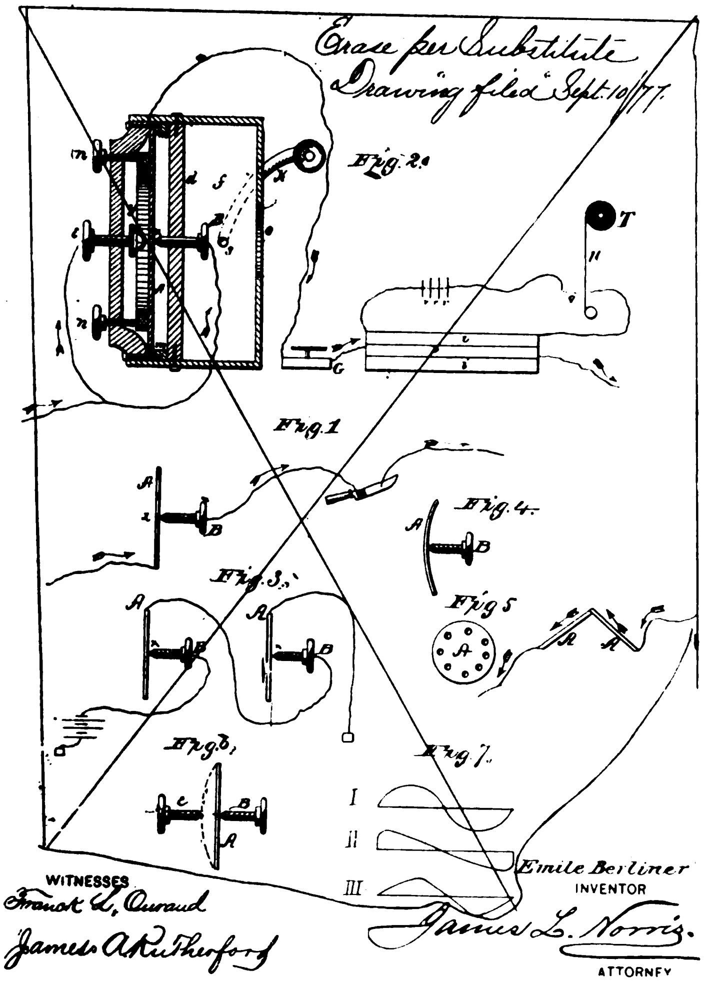
Among other large works equipped on this system by the C. & C. Co., are those of the De La Vergne Refrigerating Machine Co., of this city, which are fitted throughout with electric motors. Our engraving Fig. 3 shows a 10-foot planer in these works driven by a 10 h. p. C. & C. motor. The Brooklyn Cooperage Works, of Brooklyn, N. Y., have also been similarly equipped.

The C. & C. Electric Motor Co., who have been the pioneers in this class of work, have met with complete success in all the plants so far equipped by them and are, we think, justified in the belief that in this direction alone lies a field worthy of the best energies of electrical engineers and manufacturers. The company has now in press a profusely illustrated catalogue, describing in detail the work they have accomplished in this direction.

LEGAL NOTES.

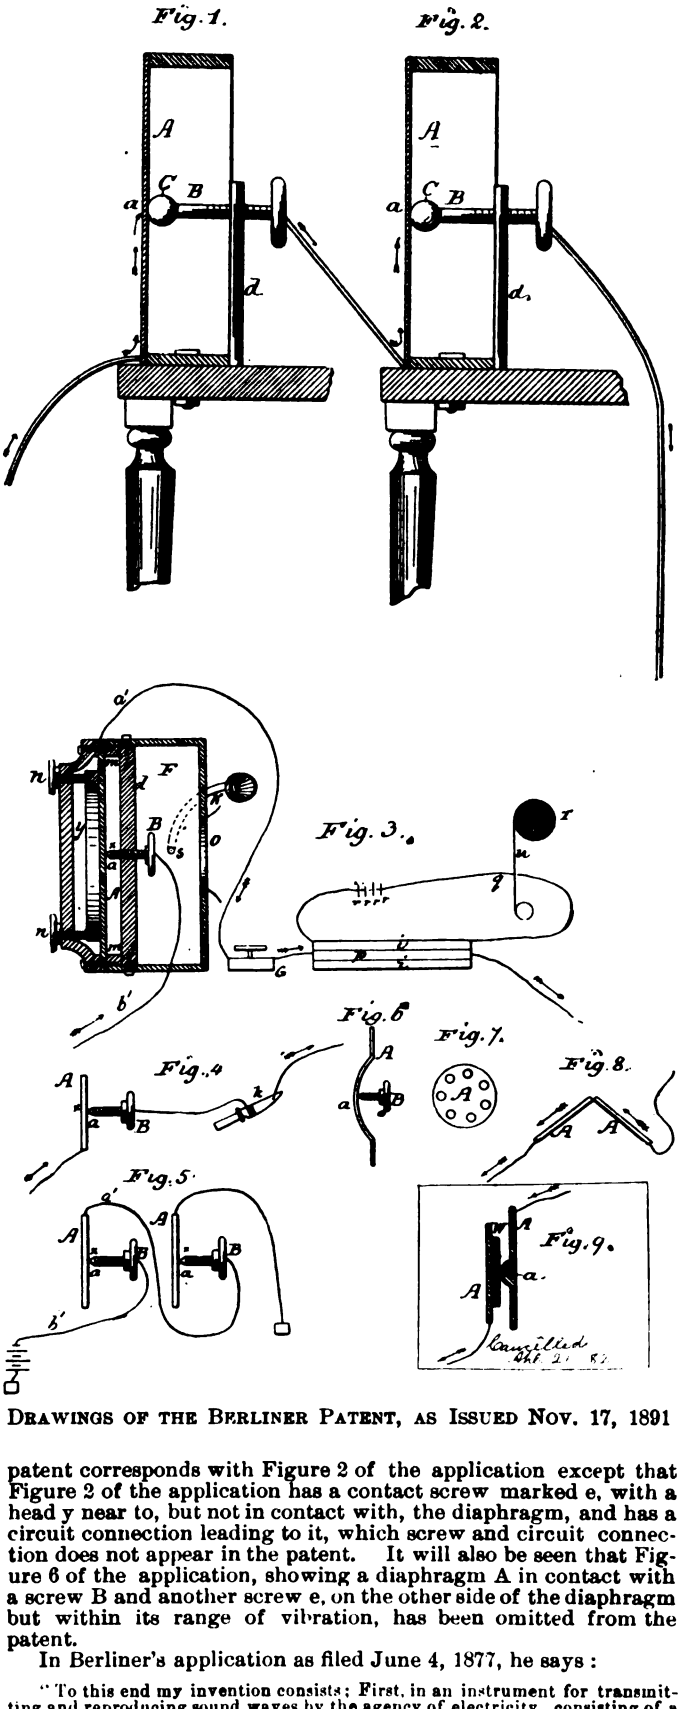
GOVERNMENT SUIT TO ANNUL THE BERLINER TELEPHONE PATENT.—II.

IN its issue of February 22 THE ELECTRICAL ENGINEER pointed out the allegation of the Attorney General's bill that Berliner's application of June 4, 1877, described a *make and break* transmitter, and that it did not describe any other kind of transmitter ; and that in the patent as issued (November 17, 1891) the *make and break* transmitter had been eliminated and a *constant contact* transmitter had been substituted.



DRAWING FILED WITH BERLINER'S APPLICATION, JUNE 4, 1877.

Below are reproductions of the drawings of the original application and those of the amended application and of the patent. It will be seen that Figures 1 and 2 of the patent are not found in the application. It will also be seen that Figure 3 of the patent corresponds with Figure 2 of the application except that Figure 2 of the application has a contact screw marked e, with a head y near to, but not in contact with, the diaphragm, and has a circuit connection leading to it, which screw and circuit connection does not appear in the patent. It will also be seen that Figure 6 of the application, showing a diaphragm A in contact with a screw B and another screw e, on the other side of the diaphragm but within its range of vibration, has been omitted from the patent.



DRAWINGS OF THE BERLINER PATENT, AS ISSUED NOV. 17, 1891

In Berliner's application as filed June 4, 1877, he says :

> "To this end my invention consists; First, in an instrument for transmitting and reproducing sound waves by the agency of electricity, consisting of a metallic diaphragm or other vibratory medium, connected to or forming part of one pole of an electric circuit, arranged in contact with the opposite pole thereof and capable of being put in vibration by the action of the electric current, as more fully herein set forth.
>
> * * * * * *
>
> Third, in the combination with said vibrating diaphragm of a pin arranged *out of contact* with the same but *within its field of vibration* and in the same

electrical circuit for producing and transmitting *special sound-waves*, as more fully hereinafter set forth.

* * * * * *

If now the plate of one instrument, as in Fig. 3, is vibrated by sound-waves, which happens whenever any kind of sound is uttered or produced by musical instruments in its neighborhood, every wave or vibration that strikes the plate will cause a weakening of the point of contact; or also if the sound is sufficiently strong, a break of the electric current at that point.

These simple instruments will produce any musical sound uttered in the neighborhood of one of them; but for the reproduction of special sounds, *such as speech, they are not adapted* for the following reasons:

* * * * * *

It is therefore evident that the apparatus described thus far can but transmit a pure musical sound because it transmits only the number of vibrations per second which is equal to the lengths of the waves, but nothing of the nature of each wave and the shape of their curves is recorded. *This I accomplish, however, by situating within the vibration field of the plate A a second screw e.* In Fig. 6 the dotted line indicates the vibrating field of the plate B, the screw in contact with the plate, and e the second screw. It will now happen in special sounds (meaning the nature of every sound besides its certain musical pitch) that the plate will not always strike the screw e in the middle of the duration of one wave or vibration, and taking for instance the duration of one wave to be one minute, the plate in special sounds will sometimes strike the screw e, sometimes after twenty or twenty-five seconds from its beginning. This now is exactly recorded on this secondary screw e, which also makes an electric connection whenever the plate A touches it, and at the receiving apparatus these special sounds will therefore be noticed. I have thus succeeded in producing a great many special sounds, such as the vowels and others. The principle of producing special sounds by *break and make of contact* rests mainly in the use of this secondary contact screw.

* * * * * *

What I claim and desire to secure by letters-patent is;

* * * * * *

4. In combination with the metallic diaphragm and its contact pin, a secondary pin out of contact with said diaphragm but within its vibratory field, and the same electric circuit, the whole adapted to operate as set forth for transmitting special sounds."

None of the matter quoted above appears in the patent. The following is quoted from the patent as issued (none of which appears in the application as filed):

"It is a fact that if at a point of contact between two conductors forming part of an electric circuit and carrying an electric current, the pressure between both sides of the contact becomes weakened, the current passing becomes less intense, as for instance if an operator on a Morse instrument does not press down the key with a certain firmness the sounder at the receiving instrument works much weaker than if the full pressure of the hand had been used. Based on this fact I have constructed a simple apparatus for transmitting sound along a line of an electric current in the following manner. In figures 1 and 2 of the drawings A is a metal plate well fastened to the wooden box or frame, but able to vibrate if sound is uttered against it or in the neighborhood of said plate. Against the plate and touching it is the metal ball C, terminating the screw-threaded rod B, which is supported by the bar or stand d The pressure of the ball C against the plate A can be regulated by turning the rod B. The said ball and plate are included in circuit with an electric battery so that they form electrodes, the current passing from one of them to the other. By making the plate vibrate the pressure at the point of contact a becomes weaker or stronger as often as vibrations occur, and the strength of the current is thereby varied accordingly, as already described. By placing now, as is shown in the drawings, one such instrument in the station Fig. 7 and another instrument capable of acting as a telephonic receiver in the station Fig. 2, both situated on the same electric circuit in which a current is passing (as shown by the wire connections following the arrows) sound uttered against the plate of the instrument Fig. 1 will be reproduced by the plate of the instrument Fig. 2, for as the vibrating of the transmitter Fig. 1 caused by the sound will alternately weaken and strengthen the current as many times as vibrations occur, the diaphragm of the receiver will be caused by these electrical variations to vibrate at the same rate and measure. * * * * *

The important claims of the patent (1, 2, 3, and 6) are as follows:

1. The method of producing in a circuit electrical undulations similar in form to sound-waves by causing the sound-waves to vary the pressure between electrodes in constant contact so as to strengthen and weaken the contact and thereby increase and diminish the resistance of the circuit, substantially as described.

2. An electric speaking-telephone transmitter operated by sound-waves and consisting of a plate sensitive to said sound-waves, electrodes in constant contact with each other and forming part of a circuit which includes a battery or other source of electric energy and adapted to increase and decrease the resistance of the electric circuit by the variation in pressure between them caused by the vibrational movement of said sensitive plate.

3. The combination, with the diaphragm and vibratory electrode, of a rigidly held opposing electrode, in constant contact with the vibratory electrode, substantially as described.

* * * * * *

6. A speaking-telephone transmitter comprising a diaphragm or disc sensitive to sound-waves, combined with a rigidly-held but adjustable electrode in contact with the same, whereby the electric current is transformed into a series of undulations corresponding with the vibrations of said diaphragm.

In its SUPPLEMENT of November 17, 1891, the day on which the patent was issued, THE ELECTRICAL ENGINEER said:

"The claims of the Berliner patent appear to be of a very broad character, and to cover an essential element in about all the transmitters employed in telephone service. * * *

"The famous interference case [Berliner-Edison] has been a theme of much curiosity and interest now these many years; little has been publicly known of its status beyond its apparent immobility. Commissioner Simonds decided against Drawbaugh, who was a party, a few weeks ago. That decision is said to have cleared the way for the allowance and issue of the Berliner patent of this day.

"It is too early to undertake any critical examination of the patent or to express an opinion as to its scope. Should it be found broad enough to control the use of all practicable microphones, it is considered doubtful, in view of the circumstances of the long delay in its issue, whether the United States Courts would sustain it to the extent of permitting its owners to enjoy its protection for the next seventeen years."

LETTERS TO THE EDITOR.

MARCH 7, 1893, HOW ABOUT TELEPHONES?

THE fundamental Bell Telephone, patent No. 174,465 of March 7, 1876, expires on March 7, 1893. What effect the expiration of this patent will have, involves a number of factors and situations which I have not thus far seen intelligently analyzed in any of the electrical journals, notwithstanding the near approach of the above-mentioned date. The popular impression seems to be that the patent of March 7, 1876, is for the telephone receiver, and that the latter will be free after the expiration of that patent. It seems more than likely that telephone receivers may be bought and sold with impunity, and be essentially free. It is not true, however, that the patent of March 7 is upon the telephone receiver as we know it to-day; the last claim of this patent involves broadly the art of the transmission of speech by the use of an undulatory current of electricity. The Bell patent, No. 186,787 of January 30, 1877, is the one which covers the telephone as an instrument, and apparently no commercial telephone can be constructed which does not infringe this patent.

It may then well be asked how is it that preparations are being made by so many individuals and companies to sell telephone receivers and in some cases to organize and operate exchanges after March 7. There are a number of reasons that may explain this. In the first place, the British patent, No. 4,765, of December 9, 1876, includes, almost verbatim, all the claims of the United States patent of January 30, 1877, and being a prior patent would seem to have invalidated the American patent after December 9, 1890, when it expired. As, however, the British patent, dated December 9, 1876, was not sealed until the following May, it may be claimed that it was not really a patent before that time, and, therefore, could not be construed as being a prior British patent. A number of decisions have been made by the courts which would seem to uphold this view of the case although the question never has been carried to the Supreme Court. Again, the only novelties covered by the second patent are the use of the permanent steel magnet and a diaphragm of iron or steel or other metal susceptible of inductive influences. The other claims of the patent seem either immaterial or to involve practically a repetition of the claim before mentioned in the patent of 1876. In fact, any possible telephone devised in accordance with the specifications and claims of the first patent would infringe the first claim of the second, which is drawn so broad as practically to patent the practical principles of the telephone all over again and thereby extend the monopoly in receivers.

Is it likely that the American Bell Telephone Company will be able to secure an immediate preliminary injunction against manufacturers of telephone receivers by virtue of existing decisions in its favor and legal precedents? If such an injunction can be procured, the telephone receiver is certainly tied up till January 30, 1894; if, however, such an injunction cannot be immediately obtained, if there be opportunities for argument and delay, as would seem likely, we may look for the purchase and sale outright of telephones in increasing quantities from day to day after March 7 as the public confidence is secured. The second patent, having only 10 months to run, it seems to be thought by those about to engage in the business, that a suit for infringement could not possibly be decided in so short a time and that the damages to be claimed, even in the event of an adverse decision, would not be commensurate with the advantage of establishing business in the meantime. Rumors are current that the American Bell Telephone Company will resurrect some of its best forms of magneto transmitters, of which it has several excellent ones, and sell them, with receivers, outright after March; if this can be done with justice to the licensee Bell companies, it would apparently be a shrewd move for the reason that the Bell Company could get better price for its instruments than the new strugglers in the field, owing to the desire of the public to purchase what it can use in peace and tranquility. A merchant would naturally, in view of the intricacies of the patent situation, rather pay the Bell Company $10 for a good set of instruments for private or speaking-tube service, than purchase similar instruments from others at, say $5 per set; especially as he would doubtless in this case receive the best magneto transmitter on the market. It is thought by some that little attention will be paid hereafter by the Bell people to the manufacturers of receivers for private line and speaking-tube purposes, but that operators of incipient exchanges will have the honor of drawing the heaviest legal fire from Boston.

It does seem problematical whether the manufacturers of receivers already starting up can be suppressed during the next 10 months, even by the promptest and most successful action of the Bell Company and the coöperation of the courts. As yet, no one has had the temerity to offer for sale, in the United States, a carbon or other battery transmitter, although telephones by the thousands are said to be ready for sale after March 7. However, the very moment the Bell Company shall fail to get its first injunction against a manufacturer or user of receivers, it seems more than likely that carbon transmitters, whose infringement of the Berliner and Edison patents is doubtful, will appear for sale, and thus will probably be the signal for a legal battle as important, far-reaching, and doubtless as long strung out, as the incandescent lamp litigation. If millions of incandescent lamps have been used during the years of the litigation establishing Edison's right to the invention, how many telephones and transmitters will be in operation before the Bell Company shall have won or lost its next great battle?

The construction and operation of telephone lines are apparently much less formidable undertakings in respect to cost and maintenance than in the case of electric lighting.

I learn from THE ELECTRICAL ENGINEER of February 22, that United States Attorney-General Miller has already taken steps on the part of the Government to annul the Berliner patent, which lay in the Patent Office some 13 or 14 years after application before it was issued.

Summing up the situation, it would appear to me that owing to the splendid and permanent establishment of the licensee Bell companies throughout the country, the superiority of their apparatus, the hundreds and perhaps thousands of patents on important details, owned by them and the Western Electric Company, together with their magnificent system of interurban communication, any new company contemplating the establishment and operation of exchanges will labor under serious disadvantages. On the other hand, the opening of private line service to the public will be a blessing to the various electrical supply and construction companies and to the electrical trade in general; for the reason that it will bring such companies into profitable contact with thousands of new customers who will be willing to pay for good work and who will pay surely and promptly. As I said before, it seems strange that no discussion of any value, of this question, has a yet even commenced in any of the electrical journals and as the foremost electrical journal published in this country, I have taken the liberty of addressing THE ELECTRICAL ENGINEER on this subject, with the hope of eliciting its opinion and drawing out the views and predictions of others.

CONSERVATIVE.

[OUR correspondent, whose letter arrives just before going to press, seems to have set forth the existing situation in respect to the telephone business and telephone patents with tolerable completeness and to have answered, in great part, the queries suggested by his letter. He probably does not expect us to assume to decide the patent questions involved in advance of their legal solution by the Courts, or to advise manufacturers to rush into the telephone field. There is no doubt, however, that the time is near at hand when competing telephones will be on the market.

EDS. E. E.]

STEADY SPEED FOR DYNAMOS.

WE are looking for a contrivance to give a dynamo steady speed from a variable one. Can you give us any information?

W. S. CHESLEY & CO.

24 Morris street,
JERSEY CITY, N. J.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEBRUARY 14, 1893.

Accumulators:—

Manufacture of Secondary Battery Electrodes, R. McA. Lloyd, New York, N. Y., 491,684. Filed Sept. 30, 1892.

Consists in subjecting a plate to the action of a solution at first acid and afterward becoming alkaline; thus first producing honeycombs in the surface of the plate and subsequently chemically depositing thereon active material.

Accumulator, W. A. Macleod, Boston, Mass., 491,726. Filed Dec. 17, 1890.

Consists of porous plates supporting the active material and having apertures passing inward from the edges.

Secondary Battery, N. H. Edgerton, Philadelphia, Pa., 491,878. Filed July 11, 1892.

Consists of a series of independent frames unsusceptible to the action of electricity, each provided with a metal plate; those in the end frames provided on one side with a layer of active material and the intermediate ones with active material on both sides.

Alarms and Signals:—

Electrical Signaling Apparatus, J. B. Currier, Lowell, Mass., 491,531. Filed Dec. 15, 1881.

A signaling system having a series of individual call bells and an automatically selfadjusting regulator interposing the air bridge in the circuit to prevent an excess of current.

Electric Governor for Signaling Circuits, J. B. Currier & D. H Rice, Lowell, Mass, 491,532. Filed Dec. 1, 1882.

Escaping Gas Alarm, O. J. Milligan, Chicago, Ill., 491,580. Filed July 23, 1892.

Time Circuit Closer, R. H. Twigg, London, England, 491,692. Filed Aug. 9, 1892.

Track Circuit, J. B. Stewart, Haverstraw, N. Y., 491,609. Filed Nov. 5, 1892.

An electric block system for steam railways.

Electric Signaling Apparatus, L. von Orth, Berlin, Germany, 491,758. Filed Apr. 14, 1892.

A system by means of which predetermined signals may be sent over telephone or other wires without impeding the traffic upon them.

Electric Alarm Money Drawer, W. J. Walker, St. Louis, Mo., 491,824. Filed Oct. 29, 1892.

Railway Train Order and Signaling Device, L. T. Crabtree, New London, Wis., 491,887. Filed Apr. 2, 1892.

Electric Signal, F. H. Clarke, Springfield, O., 491,874. Filed Oct. 24, 1892.

An electric block system for steam railways.

Conductors, Conduits and Insulators:—

Electric Motor and Dynamo Mica Insulator, C. W. Jefferson, Schenectady, N. Y., 491,708. Filed June 1, 1892.

A disc for insulating armature heads consisting of concentric rings of mica scales radiating from the centre, overlapping and cemented at their edges.

Insulator, Louis McCarthy, Boston, Mass., 491,729. Filed Aug. 8, 1892.

Consists of a case containing a connecting piece, insulating material separating the one from the other, and a cap secured in place by turning the case over its edges.

Insulator, A. L. Johnston, Richmond, Va., 491,890. Filed May 4, 1892.

An insulator provided with a well containing non-conducting liquid and having a wire hanger suspended therein.

Dynamos and Motors:—

Conductor for Armatures, E. Kolben, Schenectady, N. Y., 491,567. Filed Feb. 8, 1892.

A U-shaped bar conductor forming part of an armature coil and having one limb wider than the other with a radial saw-kerf dividing the wider limb for a part of its length.

Armature and Means for Supporting the Same, E. Kolben, Schenectady, N. Y., 491,568. Filed Feb. 8, 1892.

Consists of a ring supported upon spider arms, an armature conductor surrounding the arm, special conductors crossing the sides at the spider arms, and special conductors connected across the inner surface of the armature.

Alternating Current Dynamo Electric Machine, J. J. Wood, Brooklyn, N. Y., 491,695. Filed Oct. 30, 1890.

Employs an armature consisting of an annular core of magnetizable metal without polar projections and having two supporting rings fastened against its opposite sides and a succession of flat coils arranged against the inner surface of the core.

Alternating Current Generator, O. Patin, Paris, France, 491,811. Filed July 8, 1892.

A generator adapted to be placed directly upon the shaft of the engine in place of the fly-wheels.

Electric Motor Regulator, J. A. Williams, Canal Dover, O., 491,829. Filed Feb. 11, 1892.

A centrifugal governor having a spindle provided with a pair of friction discs and a brush-carrying arm with a toothed sector; in combination with a shaft parallel to the driving shaft and geared to the sector, and a sliding frame in which one end of the shaft is mounted and carrying a transverse shaft geared with a friction disc between the parallel discs before mentioned.

Electric Motor, A. W. Meston, St. Louis, Mo., 491,970. Filed June 15, 1891.

A motor designed to be actuated by constant or alternating current which shall be self-starting and have a positive directive tendency of rotation at all speeds, and with constant potential current self-regulating for speed.

Lamps and Appurtenances:—

Electric Arc Lamp, F. D. A. Goold, Schenectady, N. Y., 491,548. Filed Apr. 15, 1892.

Invention relates to mechanism for controlling the movement and regulation of the carbon rod.

Incandescent Lamp Socket, J. Hutchinson, New York, 491,561. Filed June 11, 1891.

Electric Lamp Fixture or Bracket, J. T. Robb, Mt. Vernon, N. Y. 491,596. Filed Aug. 31, 1891.

Duplex Electric Arc Lamp, C. E. Scribner, Chicago, Ill., 491,603. Filed Oct. 27, 1890.

Provides for burning lamps in groups of two upon the same circuit, the different members or pairs of a group being provided with the necessary circuits and mechanism to cause one lamp to burn before the other.

Electric Arc Lamp, C. E. Scribner, Chicago, Ill., 491,604. Filed Oct. 30, 1890.

Claim 1 follows:

A direct shunt around an electric lamp, said shunt containing a circuit closer, in combination with the carbon rod and a yielding guide for the carbon rod adapted to maintaining said cut-out opened or closed accordingly as the weight of the rod is placed upon or removed from the said yielding guide.

Cut-Out for Arc Lamps, C. E. Scribner, Chicago, Ill., 491,605. Filed Dec. 1, 1890.

Provides automatic means for closing a circuit around the lamp when the carbons cease to feed or are consumed.

Bushing for Incandescent Lamp Sockets, C. A. B. Halvorson, Saugus, 491,682. Filed Apr. 4, 1892.

Electric Head Lamp, W. Main, Brooklyn, N. Y., 491,718. Filed Oct. 29, 1892.

Electric Arc Lamp, W. H. Akester, London, Eng., 491,915. Filed Sept. 9, 1892.

Employs two carriers for the carbons connected by means of a flexible connection, a pulley loosely mounted from a shaft over which the flexible connection passes and a spring for normally holding the pulley shaft in a given position.

Electric Arc Lamp, W. H. Akester, London, England, 491,916. Filed Sept. 9, 1892.

Similar to 491,915.

Measurement:—

Coulomb Counter, G. Hummel, Nuremberg, Germany, 491,560. Filed Feb. 16, 1891.

A coulomb meter based upon the principle of mutual dynamic action between a fixed and movable electric conductor.

Miscellaneous:—

Ore Amalgamator, F. O. Norton, Clinton, O., 491,686. Filed Dec. 31, 1891.

Method of Electrolytically Producing Soda and Chlorine, E. B. Cutter, New York, N. Y., 491,700. Filed Dec. 30, 1891.

Method of Electrolytically Producing Potassium Chlorate, E. B. Cutter, New York, N. Y., 491,701. Filed Apr. 11, 1892.

Self Winding Electric Clock, E. Klahn, West Hoboken, N. J., 491,945. Filed Feb. 17, 1892.

Railways and Appliances:—

Electric Locomotive, S. H. Short, Cleveland, O., 491,666. Filed Jan. 16, 1891.

Employs a motor whose armature is axially placed with reference to a car axle and directly connected with it, and having cushioning material between the axles and the tires.

Directly Connected Motor for Cars, S. H. Short, Cleveland, O., 491,667. Filed Mar. 30, 1891.

Similar to 491,666.

Series System for Railways, G. L. Thomas, Brooklyn, N. Y., 491,691. Filed June 16, 1892.

Invention contemplates a single line wire posted along the path of the moving vehicle and adapted to be intercepted by the vehicle to make with an insulating circuit within the vehicle a part of the single line circuit.

Electric Locomotive, F. B. Rae, Detroit, Mich., 491,857. Filed Apr. 11, 1891.

Relates especially to the manner of mounting the motor and connecting it with the running gear.

Telegraphs :—

Telegraph Transmitter, R. S. Roberts, Philadelphia, Pa., 491,595. Filed 29, 1892.

An automatic transmitter employing two angle levers, an axle journaled in and supporting the levers and transmitter, and a wheel mounted on the transmitter; the axle and transmitter being insulated from the other parts of the instrument.

Telephones and Apparatus :—

Trunk Line Signaling Apparatus and Circuit for Telephone Exchanges, E. J. Hall, Morris, N. J., 491,558. Filed Oct. 13, 1892.

Employs a divided switchboard, a double conductor trunk circuit and office trunk conductors with inter-station trunk conductors, fitted with a reciprocal signaling system whereby connections and disconnections at either end are indicated at the other.

Switching System for Telephone Exchanges, C. E. Scribner, Chicago, Ill., 491,688. Filed May 19, 1892.

Memorandum Tablet for Telephones, W. M. Kleeman, Columbus, O., 491,777. Filed Apr. 11, 1892.

Telephone Call, J. H. Kinsman, Bridgeport, Conn., 491,898. Filed Jan. 20, 1892.

INCANDESCENT LITIGATION.—THE NEW WESTINGHOUSE LAMP.

THE Westinghouse company having been enjoined December 27, 1892, in the U. S. Circuit Court, at Pittsburgh, from making lamps infringing the second claim of the Edison patent—in accordance with the Appellate Court decisions in New York against the United States and Sawyer-Man companies, soon after put upon the market their new "stopper lamp" as a lamp not infringing the Edison patent, and on February 1, presented an affidavit to the same court, setting forth these facts, and obtained a rule upon the plaintiffs, Edison Electric Light Co. *et. al.* [General Electric Co.] to show cause why the injunction should not be so construed, or restated as to leave defendants free to make, use and sell their "stopper lamps." The plaintiff moved the court to reverse this rule, and the case was argued by counsel on both sides a week later. [See THE ELECTRICAL ENGINEER, February 15].

On February 23 the Court (Acheson, *Cir. J.* and Buffington, *J.*) handed down on opinion, by Judge Acheson, from which the following is quoted:

"While we are quite prepared to accept the defendants' course in taking this rule as evidence of their good faith to the Court, and as indicating a purpose to avoid even the appearence of any wilful disobedience to our writ of injunction, yet, under all of the circumstances we think it would be going too far at their instance and in this summary way, to enter upon the consideration of the question whether the lamp now submitted to us infringes the patent in suit. This lamp was not before the Courts of the Second Circuit, and the question of infringement involved in this rule is entirely new. Undoubtedly there is a marked difference in structure between this stopper-lamp and lamps such as Exhibits Nos. 1, 2, and 3 which we have specifically enjoined, but enough appears to satisfy us that the question of infringements cannot be determined safely upon a mere inspection of the lamp. No investigation would be complete without the aid of expert testimony and evidence touching the art of electric lighting in its earlier stage, But *ex parte* affidavits upon these subjects (and this rule contemplates nothing more) would be most unsatisfactory. Moreover, should the rule go to hearing on the merits, the action of the Court thereon would be inclusive.

But furthermore, if the question whether the defendant's stopper lamp infringes the second claim of the patent in suit can properly be considered at all upon a mere rule to show cause, the party invoking the rule, we think, should be the plaintiff, to whom it is, of course, open to apply for an attachment against the defendants for the alleged violation of our injunction. In the absence of such an application by the plaintiff, the consideration of this question must await the final hearing. Then we may be called on regularly and properly to decide the question, for clearly the relief obtainable under the present bill is not limited as respects either an injunction or an account to infringing lamps made before the institution of the suit, but equally embraces those made afterwards although structurally different from the former ones. *Story's Eq. Pl.* Sec. 352; *Knox* v. *The Great Western Q. M. Co.*, 5 Saw. 430; *Rubber Co.* v. *Goodyear*, 9 Wal. 788.

The rule to show cause granted February 1, 1893 will therefore be discharged, but without prejudice to the defendants' rights to set up in their answer the matters upon which said rule was founded.

And it is so ordered.

WESTINGHOUSE ELECTRIC RAILWAY WORK.

ORDERS for electrical railway equipment taken by the Westinghouse Electric and Manufacturing Co., since January 1, amount to nearly $2,000,000. It is reported that the company has orders for about 4,000 street railway motors.

THE BOUGHTON TELEPHOTOS.

ON the evening of Feb. 9th, the members of the Buffalo Electrical Society and their friends were entertained by Mr. C. V. Boughton, the inventor of the "telephotos" at his works on Seventh St., Buffalo.

The "telephotos" is designed for the purpose of communicating between ships at sea, armies in the field, and for other similar purposes now usually accomplished by means of rockets, flags and other visual devices. Among the advantages claimed for Mr. Boughton's invention is the facility with which such communications can be effected, the compactness of the apparatus, which permits of easy of transportation, and the unlimited scope of the communications. The Morse telegraphic code of dots and dashes is employed for signals which are produced by means of incandescent lamps, operated by dynamo currents and controlled by a key-board on which the characters are designated or marked by Roman letters, thus enabling any one, whether familar with the Morse code or not, to transmit despatches, which must, of course, be received and translated by an attendant, expert in reading those characters.

The lamps employed to produce the dots and dashes are arranged in a vertical, or horizontal line and are of the ordinary 32 c. p. make. The lamps are placed in individual pockets with suitably arranged reflectors for projecting the rays of light. There are 106 of these lamps, two of which are glowed to produce a dot, 20 to produce a dash, and 20 intervening lamps left unilluminated to effect the space between the dots and dashes. 60 lamps are glowed for a long dash representing the cipher, or naught, and two red lamps denote a period.

The lamps are controlled by a key-board not dissimilar to the key-board of the conventional typewriting machine. The case is made of aluminum, to secure lightness, and is contained within an area of two and one half feet square, with a depth of six inches. The keyboard, comprising 37 letters, numerals, etc., occupies one foot and six inches; the remaining portion is taken up by the electrical connections, of which there are necessarily a large number. The manner in which the multifold connections necessary to energize the required number of lamps to produce any required letter when the key is depressed are made, is easily understood by imagining a flat commutator, having a segment for each lamp, against which is pressed a metallic bar covering all of the segments, on the face of which are gaps over the segments connected with the lamps not to be energized in producing the letter represented by the key depressed.

The keys are marked by letters and figures on rollers running across the keyboard which are simultaneously revolved by a thumbscrew and ratchet at the side of the machine. As each side of the rollers has a sequence of letters, etc., starting from a different letter of the alpabet, secret signaling is effected by a transposition of the alphabet and the code. When the rollers are in their normal position the letters correspond with the Morse characters produced, but when the rollers are turned, depressing the key designated by the letter "A" may cause the Morse "B" to be shown by the lights, or any other predetermined Morse character. Attached to the keyboard is a very ingenious and simple device, the invention of Mr. Boughton, which locks all the keys except the one depressed and prevents more than one key being depressed at a time. Mr. Boughton has also applied this device to typewriting machines, where it will fill a long felt want.

The key and the lamp boards are connected by a cable containing the requisite number of conductors, and may be of any length desired. The weight of the keyboard is about 75 pounds and that of the lamp frame 120 pounds. It is stated that the weight of a wagon all the apparatus necessary for field operation, including boiler, engine and generator, will not exceed 1,500 lbs. Mr. Boughton has demonstrated that his signals can be read at a distance of three miles by daylight and ten miles at night. He feels confident that these distances can be increased. The apparatus can be worked at a speed of fifteen words a minute, and has the advantage of greater scope and precision than any other method of signaling in vogue.

PARTRICK & CARTER COMPANY.

THE PARTRICK & CARTER COMPANY of 125 South Second Street, Philadelphia, report that they are having increased sales of their automatic set back annunciator, which has been described and illustrated in THE ELECTRICAL ENGINEER. Each new call registered upon this instrument resets the pointer, so that no confusion is possible, and the annoyance of resetting by hand is avoided.

The automatic annunciators are handsomely made in a variety of woods, and present an ornamental appearance, while their freedom from all complicated mechanism insures their durability.

THE PERU ELECTRIC MANUFACTURING COMPANY, of Peru, Ind., announce that Mr. P. C. Burns has severed his connection with them and disposed of all his interest in the company.

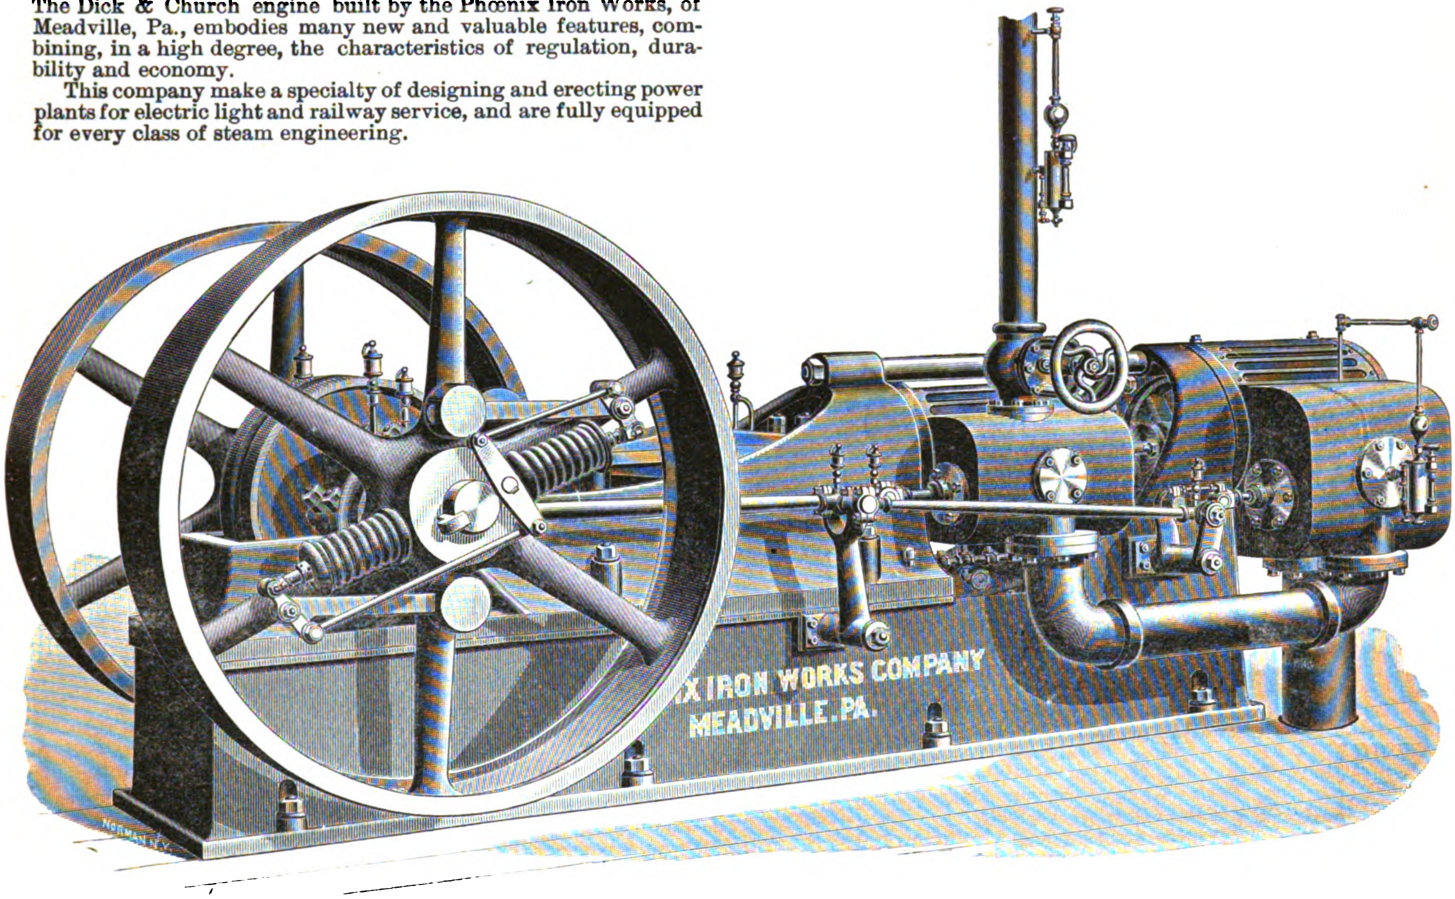
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE DICK & CHURCH ENGINE.

The introduction of the high speed automatic cut-off engine marks an important era in the development of the steam engine, particularly as it has so largely contributed to the successful development of the dynamo as a vehicle for the transmission of energy. No other type of engine has been able to fulfill the various and exacting conditions imposed, and the peculiar adaptability of the high speed engine to electrical work is now universally conceded. In spite of the arguments that have been advanced, in the past, against this type of engine, it has steadily increased in public favor, and the later developments have fully demonstrated that the high speed engine can show the very best results. The Dick & Church engine built by the Phœnix Iron Works, of Meadville, Pa., embodies many new and valuable features, combining, in a high degree, the characteristics of regulation, durability and economy.

This company make a specialty of designing and erecting power plants for electric light and railway service, and are fully equipped for every class of steam engineering.



The Dick & Church Tandem Compound Engine for Electric Lighting.

It is a well recognized principle in conducting all manufacturing and power producing plants that the measure of profit is more largely dependent upon the cost of the actual power production, than upon any other factor that enters into the economy of management, and it is therefore to the steam plant, as the prime motor, we must first look for results, as it is here the greatest loss generally occurs. The theoretical deduction that it is possible to expand the steam in a single cylinder, to a point so near the atmospheric pressure as to give the most economical results, has been shown to be fallacious by practical demonstration. This theoretical deduction does not take into account what practice has so clearly shown, viz., the wasteful condensation of steam in the cylinder, due to the excessive range of temperature between the boiler and exhaust pressure. It is for this reason that the limit of expansion in a single cylinder is soon reached, and experience has here demonstrated the advantage of the compound engine, an example of which is shown in the accompanying illustration, inasmuch as each cylinder is subject to a greatly reduced range of temperature variation, and also because of the diminished effect of clearance, retaining at the same time all the advantages of compression. The reduced initial thrust is also an important mechanical advantage in this type of engine, particularly in those of large powers. Not only in marine, but in stationary practice as well, is the compound engine rapidly taking the place of the single cylinder engine, as it has been found that the saving effected will amount to the entire extra cost in a short time. The actual first cost of a steam plant, with the compound engine, is little, if any, more than with the single cylinder engine, for much less boiler capacity is required and there is also a corresponding reduction in the other portions of the steam plant. These engines will be furnished adapted to run non-condensing when water for condensing purposes is not available, and while the saving in fuel is not as great, it is, nevertheless, so near that of the condensing engine, and so much in advance of the single cylinder engine, as to make its use imperative in all plants where fuel is a matter of any consideration.

THE ELECTRIC SELECTOR AND SIGNAL COMPANY.

With the assent of 99 % of the stock and bondholders of the Electric Secret Service Company, all of the property, patents, business and good will of that Company were sold by C. P. MacKie, Receiver, on February 11th, 1893, to the Electric Selector and Signal Company. This new corporation has likewise acquired other important inventions relating to the general subject of electrical selection, and proposes to develop this especial business as applied to telegraphs, block signals, electric light and power and telephones in this country and abroad, on a larger scale than the Company which it succeeds. The change has been effected without interruption of the business of the Electric Secret Service Company, and upon terms which provide for a settlement of all of that Company's obligations in full in cash. The Electric Selector and Signal Company will, we understand, have the same technical management as the Electric Secret Service Company, although its board of directors will contain several new and influential names.

CLARK ARC LAMP.

The Clark Electric Company, of 193 Broadway, manufacturers of arc lamps for both arc and incandescent circuits, have issued a new catalogue of their apparatus, including lamps, dynamos, regulators, etc. The lamps made by this company, especially designed for interior illumination, are got up in ornamental and graceful forms for the purpose, while those for out-of-door work are built for service and with an eye to simplicity of construction. The company have received a number of medals and many testimonials bearing witness to the excellence of their appliances.

NEW QUEEN MEASURING INSTRUMENTS OF PRECISION.

Queen & Co., Incorporated of Philadelphia have recently put upon the market some electrical measuring instruments, so original in design and efficient in use as to call for special mention. As it would be difficult at this time to mention all of this new apparatus, we shall confine ourselves to a description of two pieces which we consider most important in practical engineering.

Fig. 1 shows their new form of D'Arsonval galvanometer. The magnet is horizontal, circular in form, and built up of a number of discs stamped from sheet steel. The pole faces are shaped so as to give readings on a straight scale exactly proportional to the currents measured. The coil is long, narrow, and circular in cross section, and is fastened in an aluminum tube which forms part of the movable system. No iron core is used. The suspension tube is fitted with a movable bottom, which when raised lifts the coil so as to relieve the suspension, and clamps it tight. This prevents any injury during transportation. The whole suspension tube can be lifted out and replaced by another, automatic sliding contacts being made as the tube is put in position. To use the instrument, all that is necessary is to lower the bottom gently and relieve the coil. The mirror is so arranged that the axis of rotation lies in the centre of the reflecting plane and the mirrow window of the cage is tilted to prevent reflection from its surface.

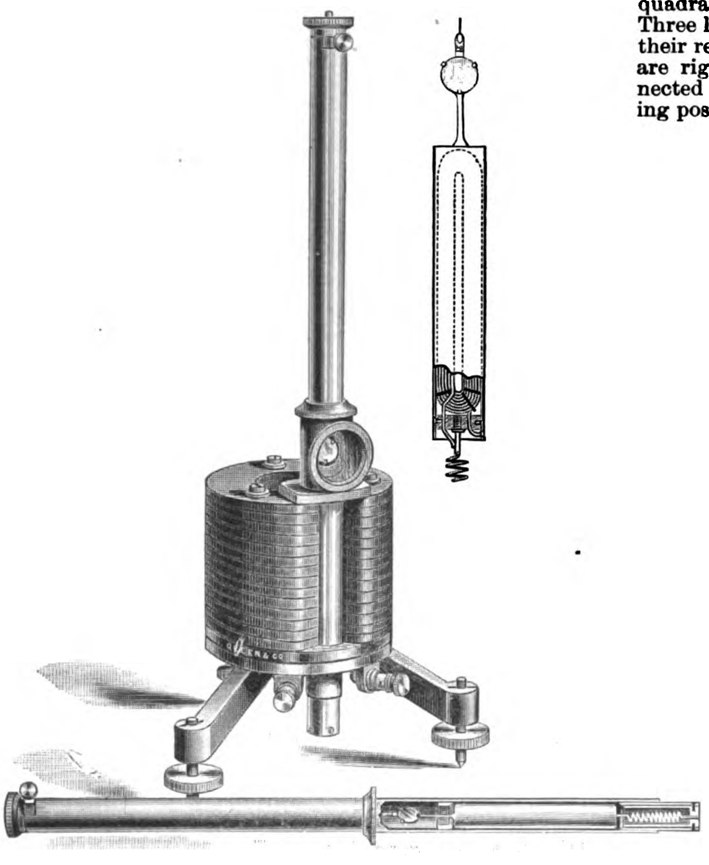


Fig. 1.—New Queen D'Arsonval Galvanometer.

The instrument is sensitive to a high degree, and being absolutely uninfluenced by strong and varying fields, or mechanical vibrations, gives accurate results when used in a dynamo-room as when used on a brick pier in a laboratory. It therefore extends the range of usefulness of a highly sensitive galvanometer far beyond anything yet reached. For general use the motion is made absolutely dead beat, so to obviate the necessity of using "tapper keys" and to save an enormous amount of time, which is very important when rapid and exact work is demanded. This should recommend it to central station men, as well as to professors. Tubes are also made for ballistic work in which the damping effect is lessened, and in this connection a bifilar suspension has been used.

With two suspensions of .0015 inch thick phosphor-bronze strip 20 inches long and $\frac{3}{32}$-inch apart and a coil of 703 turns of No. 40 copper wire whose resistance is 450 ohms, a throw of 25½ cms. with one microfarad and one Carhart cell and a period of 10 seconds was obtained. When used as a ballistic galvanometer, the coil on being thrown to the end of the scale may in every case be brought completely to rest in from 12 to 15 seconds by merely short-circuiting. The instrument can also be used for thermal work and with a suspension of phosphor-bronze strip rolled from .002-inch round wire, spring .00004 volts per degree C. change, a deflection of 1.9 cms. per degree change was obtained. It is certainly a very remarkable instrument, being second in sensibility only to a high grade Thomson galvanometer, and second to none in being uninfluenced by varying external fields or mechanical vibrations.

Fig. 2 represents the Ryan electrometer. This instrument was designed by Professor Harris J. Ryan, of Cornell University. for measuring potential difference, either direct or alternating. The quadrants, four in number, are mounted on two quartz discs, set on the inside of two metal cover plates that protect the system, and are faced with mica to prevent short-circuiting should the needle happen to touch them. The needle is cylindrical in shape and can be hung with either quartz or silk suspension. It is situated exactly in the centre of the cover case, and just above it is fastened the mirror whose silvered surface contains the axis of rotation. The cover case is made of two parts symmetrically disposed with respect to the system, and held in position by a spring clip. In this way both parts, each carrying a pair of quadrants, can be lifted from the frame so that it can be inspected. Three little pegs over which half of the cover plate fits, insure their returning to the same relative position. Opposite quadrants are rigidly connected by metal strips, the two pairs being connected to binding posts on the outside of the cover case. A binding post also on the outside of the cover case connects with a hook on the inside, from which a connection is made with the needle by a platinum wire .0002-inch in diameter.

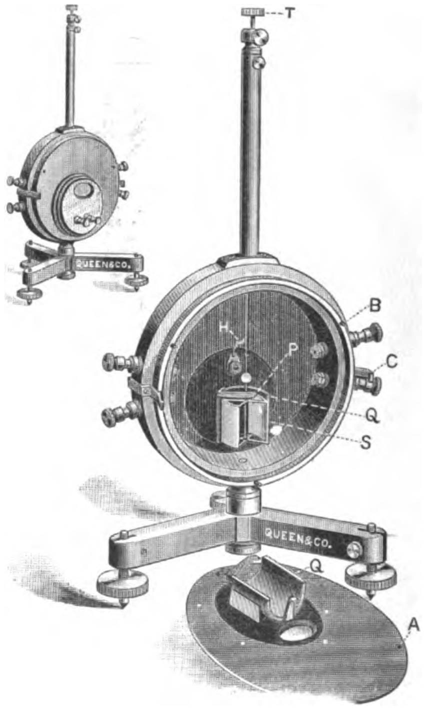

Fig. 2.—The Ryan Electrometer.

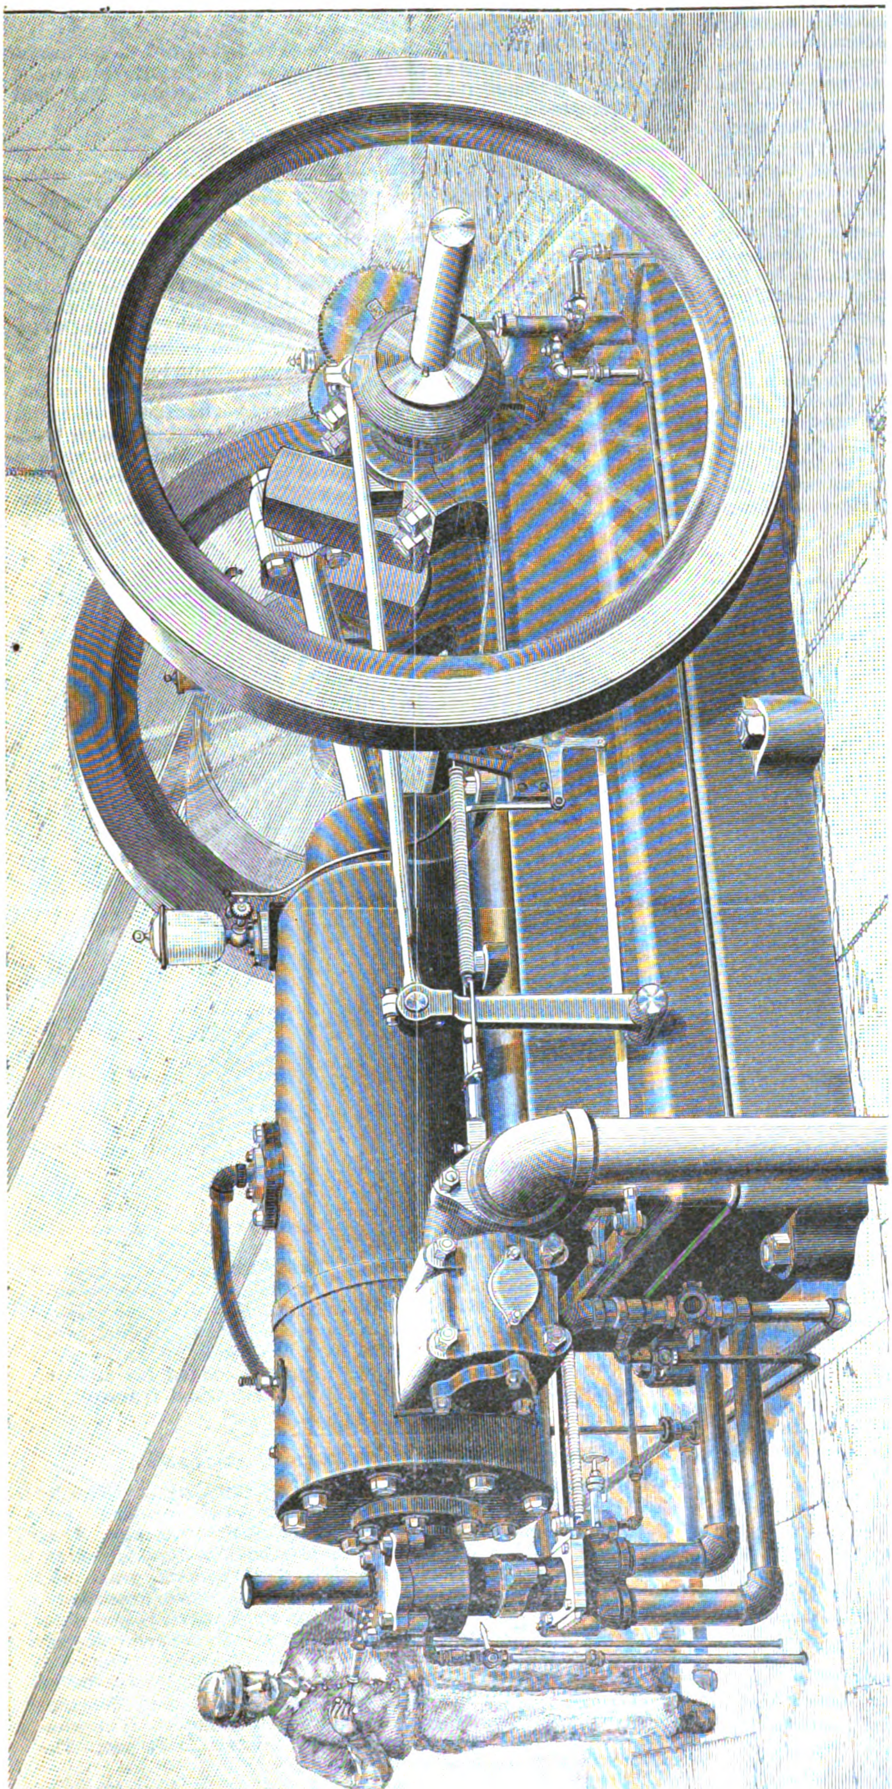
On the circumference of the cover case, and symmetrically disposed with respect to the system, are two wound coils, one of coarse and the other of fine wire. These enable the instrument to be used in both ways; either the E. M. F. may be calculated from the deflection it produces, this being measured by a scale and telescope, or else a zero method may be used, in which the needle is brought back to zero, after being deflected by the action of a current passed through the wound coils mentioned above, and the E. M. F. calculated from the magnitude of this current. This latter has the advantage of giving results unaffected by changes in the earth's field. The instrument can be used with equal success on direct and alternating circuits, as it takes no current and has no induction to be corrected for. It takes up very little room, is strong in construction and recommends itself as much for commercial as for laboratory work. It is especially advantageous in determining the efficiency of transformers by the "three electrometer reading" method.

The above instrument together with various other new forms of standard measuring apparatus, are described in a handsome supplement to catalogue I—66, recently issued by Queen & Co., Incorporated, who will be pleased to forward a copy to interested parties.



The Caldwell Gas Engine for Electric Lighting.

THE CALDWELL GAS ENGINE FOR ELECTRIC LIGHTING.

It has been completely demonstrated that by the employment of gas to drive a gas engine and dynamo more light in candle power can be obtained than if the same amount of gas is burned in the regular gas light burner. If to this we add the fact that a gas engine requires no fireman and leaves no ashes, is smokeless and cleanly in the highest degree, it is evident that it fills a place in electric lighting which, though even now appreciated, must in the future make it a prominent factor not only in isolated plants but in central stations as well. Indeed, not a few gas companies operating electric lights, both here and abroad, have recognized the advantages of the gas engine and employ it with marked economy.

Perhaps one of the reasons for the slow introduction of the gas engine for this class of work is due to the fact that until recently these engines were built in sizes reaching barely above 30 h. p. and hence necessitating a number of engines where any considerable number of lights was demanded. Happily this condition of affairs now no longer exists as we are able to illustrate in the accompanying engraving a gas engine of no less than 100 horse power.

One of these engines, which are built by Messrs. H. W. Caldwell & Son Company, of Chicago, Ill., is now in use at the the large grain elevator of Taylor Brothers, at Cooper's Point, Camden, N. J. The engine is operated by carbureted air, consisting of a mixture of common air and gasoline vapor. This provides a fuel which is not only invariable in quality, but is quite inexpensive. In large quantities the gasoline costs six cents per gallon in large cities, and as this engine is operated by one gallon of 74° gravity gasoline per horse power for ten hours, it will be seen that the cost of fuel is very light compared with the power yielded.

The cylinder has a bore of 16½ inches and the stroke is 24 inches. The crank shaft has a speed of 150 revolutions per minute. The gasoline is drawn directly from a tank considerably lower than the the engine, and its vapor is mingled with the air without any special carbureting device. The governor limits the number of charges admitted to the cylinder by controlling an air gate over one of a pair of air tubes shown at the rear of the engine. The air gate has two ports and allows air to be drawn through either tube according to the action of the governor. In one tube there is a nozzle leading upward from a reservoir containing less than a pint of gasoline, and when the port above this tube is opened the engine takes in an explosive charge. The charges are ignited by an incandescent tube incased in a larger tube lined with asbestos.

Heretofore, one objection to large gas engines has been the use of tube timers; in this engine they are entirely dispensed with. Another objection to large gas engines has been the difficulty in starting; in some cases, small auxiliary engines have been used for this purpose. All this is obviated in the Caldwell engine by the use of a novel self-starter, which consists of a hand pump used for forcing the charge into the cylinder and a detonator for exploding the charge after it has been introduced. This device gives the engine its first impulse, after which it continues to operate steadily with its automatic gear.

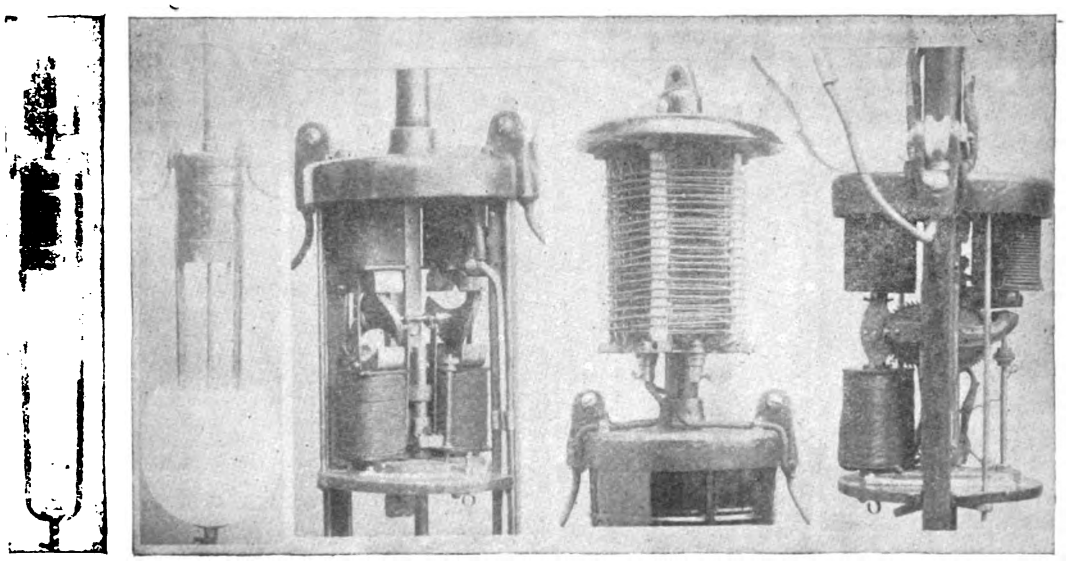
The engine, which is the invention of Mr. James A. Charter, well known in the gas engine business, has been thoroughly worked out mechanically and is built in the best possible manner.

THE NEW MOSHER ARC LAMPS FOR DIRECT AND ALTERNATING CIRCUITS.

THE new Mosher arc lamps for direct and alternating circuits, are the result of four years of experiment and practical tests, and as now constructed possess many novel and economical features. In their construction there is used both clutch and clock feed, the former for multiple arc, and the latter for series work, which feeding mechanism commends itself for its simplicity. The lamp is provided with switches, cut-outs, etc., so that when the carbon is burned out the lamp will be automatically cut out of the circuit.

The accompanying engraving Fig. 1 shows the lamp with the case on complete, with rheostat mounted on the frame, the latter feature being patented by the company. The lamp is furnished with either clutch or clock feed, to burn singly on from 50 to 125 volts for inside use. When it is used for external, or outdoor work, it is furnished with a wire-support. It requires no hood, but a hood is furnished when desired.

Fig. 5 shows the internal mechanism of the lamp, Style C 12. This lamp in its outward appearance, with the case on, is similar to the former, but is provided with a compound rheostat and cut-out. This compound rheostat, Fig. 4, is mounted on the lamp; one winding is a very low resistance, and is in circuit all the time, and the other is equal to the resistance of the arc of the lamp when burning, and is automatically cut-in circuit when for any reason the arc is broken. This insures the perfect working of the other lamps should one or more in the same series refuse to work from any cause.



FIGS. 1 TO 5.—MOSHER ALTERNATING AND DIRECT CURRENT ARC LAMP.

Fig. 2 represents the new Mosher alternating lamp, Style F 13, complete, ready for putting in circuit. No extra resistance is required with this lamp, which is wound for from 50 to 55 volts.

The engraving, Fig. 3, shows the internal mechanism. It will be noticed that the carbon is controled by rotary motion. All connections are made in such a way that it is impossible for them to get loose and rattle. In the construction of these lamps all wearing parts are so constructed, that the natural wear is taken up automatically; therefore, they can never rattle, or "sing," a feature so objectionable in all alternating arc lamps previously manufactured.

The railway circuit arc lamp, known as Style R 15, is constructed mainly for use on railway circuits, and can be made to run from 5 to 10 in the series on a 500 volt circuit. These lamps are constructed with a rack feed, and are wound to vary from 6 to 10 amperes, according to the light desired. The arc forming mechanism is operated by an armature which separates the arc the desired distance to start with, and after that does not vary. The feeding mechanism is controlled by separate magnets, one in shunt, and one in the main circuit, which releases the escapement and allows the lamp to feed only when the arc has passed beyond, or attempts to use more, than its proportionate share of the voltage of the system on which the lamp is run. The main circuit magnet is wound in such a relation to the derived circuit, that when the lamp is regulated for certain amperage, it will be impossible for the amperage to vary very much from the amount for which the lamp is regulated. That is, if the lamp is regulated for seven amperes, and the voltage of the system should decrease, the same amperes would be practically maintained, thus preventing the arc being broken by reason of insufficient pressure. If the voltage should increase, the lamp would not feed until the current had reached the normal, or seven amperes; so that it is almost impossible to burn a lamp out. This regulating magnet can be made as sensitive as it is possible to be made, as vibrating or pumping of the magnet will not interfere with the arc, and it is therefore unnecessary to use a dash-pot. This will be appreciated by lamp users.

TO STUDY INSULATION AND INSURANCE ABROAD.

MR. WILLIAM MCDEVITT, Chief of the Electrical Department of the Philadelphia Fire Underwriters Association, sailed for Europe on the North German-Lloyd Steamship *Lahn* on Feb. 21st, 1893. Many claims have been made by authorities in foreign countries of superior methods in the distribution and use of the electric light, especially as to "wiring" and its application to houses and for safety from fire. This subject Mr. McDevitt will particularly inquire into, and he will also examine the safeguards used for the protection of theatres. Philadelphia has the largest number of electric lighting stations of any city in the United States. This class of risk has almost been refused insurance throughout the country owing to the number which have been burned down—yet Philadelphia has never even had a serious fire in a single station. Mr. McDevitt will visit Berlin, London, Paris, Vienna and Marseilles, and goes at the request of nearly all the electrical contractors, central stations and electrical engineers in the city of Philadelphia who are interested in this work, and who believe that our methods are not very far behind.

The Philadelphia Fire Underwriters Association has granted Mr. McDevitt a two months leave of absence, and he carries with him letters from Hon. Edwin S. Stuart, Mayor of the city of Philadelphia, to the municipal authorities abroad, besides other letters which will give him the entree to all places he may wish to visit. A very full and interesting report is looked for and one which cannot fail to be of great use to the electrical fraternity in general.

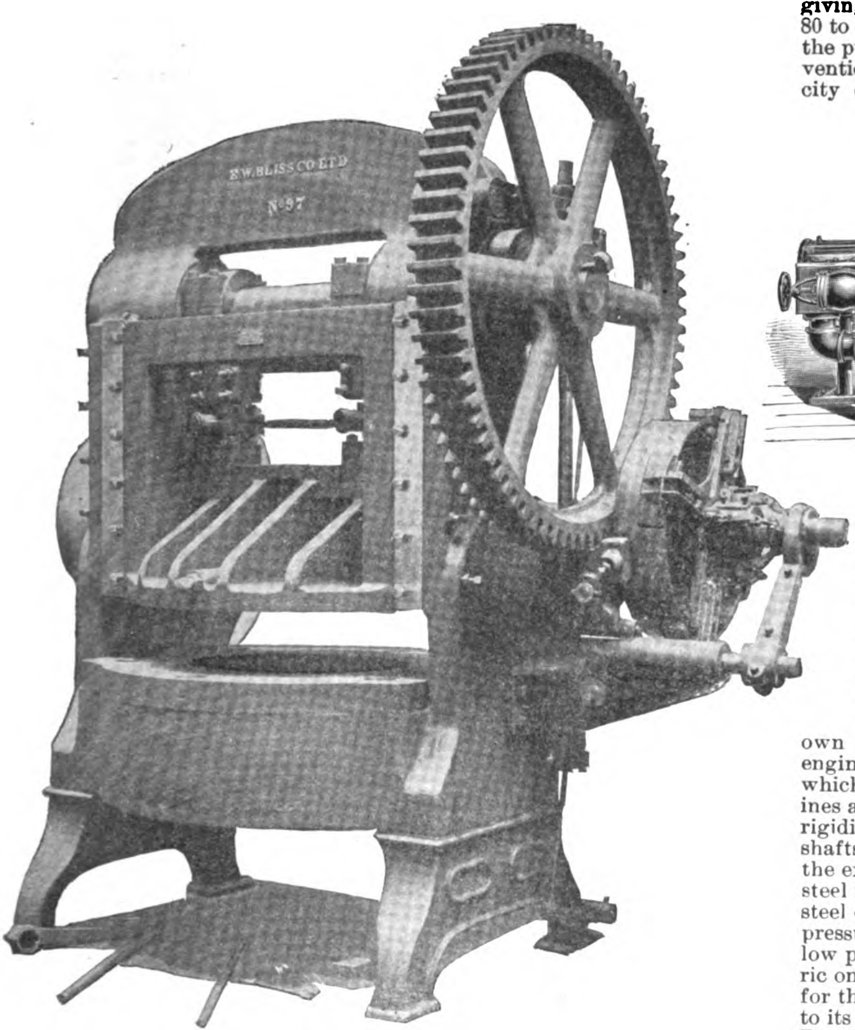
CROCKER-WHEELER ELECTRIC COMPANY.

AN important step has been taken by the Crocker-Wheeler Electric Company in the purchase of the entire property and plant of the Spiral Weld Tube Company, at East Orange, N. J., whither they will move about the middle of March, establishing offices down-town for the convenience of their city trade and out-of-town visitors. They are now purchasing heavy machinery, cranes, etc., for the shops, and putting in Western Union telegraph and Long-Distance telephone wires. A railroad station will be built for them at the factory. It will be called "Ampere," and all trains will stop there. In the factory there will be no lines of shafting, but the tools, etc., will be driven by Crocker-Wheeler motors, taking current from a central plant. The company now has a capital stock of $350,000, selling above par. The demand for its motors is enormous.

F. P. LITTLE of F. P. Little & Co., Buffalo, was a World's Fair visitor last week and was a caller at the ENGINEER'S Western office.

THE BLISS CUTTING PRESS.

The accompanying illustration shows a press for cutting out large armature discs recently built by the E. W. Bliss Company of Brooklyn, for the General Electric Company of Schenectady, N. Y. The construction of this press embodies a number of special features which have not heretofore been used in connection with presses of this class. In order to give a firm support and accurate guidance to the large and delicate dies, the ordinary centre gib has been abandoned and the ways of the slide are spread apart so as to be as wide as the frame itself. This has also made it possible to lengthen the ways considerably without increasing the height of the frame. The additional solidity and accuracy due to this mode of construction is plainly seen. Another special feature is the application of a new automatic friction clutch which obviates entirely many of the difficulties experienced with the regular automatic clutches on heavy back geared presses. Its application and construction will be readily understood. A pressure on the foot treadle shown, releases the weight which actuates a powerful friction clutch on the back shaft, thus starting the press almost instantaneously and obviating entirely the heavy metallic blow, which in the ordinary clutches tends to destroy the parts and frequently causes expensive delays and repairs. After the shaft has made one complete revolution a cam releases the friction clutch, bringing into action at the same time a brake and thus stopping the slide at the highest point of its stroke. The large gear wheel instead of revolving continually, is, with these new clutches, keyed on the shaft, and at a standstill until the clutch is thrown into action. This constitutes an additional advantage in the saving of considerable wear on the shaft and wheel hub.



The Bliss Cutting Press.

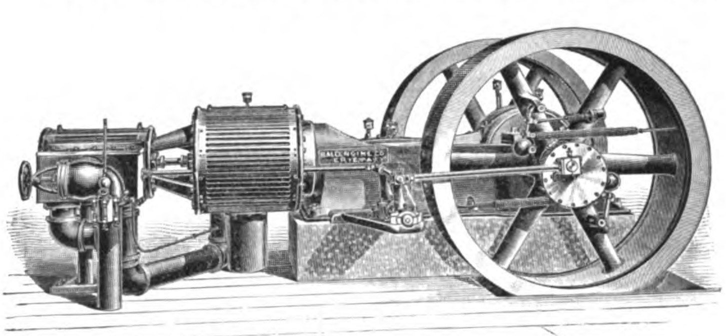
There is nothing about these clutches which is liable to get out of order, and for whatever wear may be occasioned by continuous use easy means of compensation are provided. This press will cut armature discs 30 inches or more in diameter. It has a distance between the housings of 51 inches and is generally made with a 30-inch round opening in the bed, which, however, can be varied to suit special requirements. It is geared 1:10 and has a fly wheel weighing 1800 pounds on the back shaft. The weight is 30,000 pounds.

The E. W. Bliss Co., also make a large variety of smaller presses of this class, many of which are now in use in nearly all the large electrical works.

---

400 H. P. TANDEM COMPOUND BALL ENGINE.

This engine is an outgrowth of the experience of The Ball Engine Co., of Erie, Pa., in the manufacture of engines of smaller capacity, adapted to the work of driving street railway generators; the demand from this service for economical motive power within small space and safety of operation being such that this type of engine is now found to be a winning competitor with single cylinder Corliss engines of 28 inches x 48 inches to 26 inches x 60 inches cylinder capacity and wheel diameter of 20 feet. In this engine the stroke is made short for the purpose of raising the number of revolutions and reducing the wheel diameters so as to more nearly approach the diameters of the generator pulleys, giving better belt contact. The range of wheel diameters is from 80 to 112 inches, which enables the engine to drive directly on to the pulleys of the different makes of generators without the intervention of line shafts or other divices for raising the lineal velocity of the belts, this being accomplished within economical ranges of piston speed, *i. e.*, 600 to 700 feet per minute, and perfectly reasonable as well as economical steam preasure, *i. e.*, 100 to 115 lbs.



400 H. P. Tandem Compound Ball Engine.

The engine herewith illustrated is one of several which have been put in operation within the past year. It is perfectly balanced and does not require the enormous foundation which its slow speed competitor is obliged to have, one of them giving the most satisfactory results at a speed of 210 revolutions on a pier of its own length, 17 feet high, piercing a comparatively light engine room floor, 14 feet pitch from the basement floor, on which is located all of the steam plant outfit other than the engines and dynamos. The engine is endowed with great strength, rigidity and long living powers, owing to the form of the frame, shafts, cylinders, heads, and reciprocating parts; the latter, with the exception of the pistons and wrist-pin boxes, being of forged steel from tip to tip. The shaft is of one solid piece of forged steel of a grade that is most excellent for the purpose. The high pressure valve motion is derived from the governor, while the low pressure valve is driven by direct connection from an eccentric on the other side of the engine, this eccentric being adjustable for the purpose of making a more perfect adaptation of the engine to its load when the actual running conditions are demonstrated. The valves of the "nearly" balanced type, are absolutely steam tight, and will remain so, indefinitely, as the wear is so trifling that a few hours of scraping, it is said, will renew the faces and make them as good as when first started, after two or three years run of 10 to 18 hours per day. The general features of the engine are suggestive of correct location and distribution of the parts and materials involved. If one will consider the facts existing in a compound engine, it will be found that in the underloaded state, the high pressure cylinder does the most work, the total of which does not represent a destructive strain on any of the parts, but as the load increases and gets beyond the medium line where the work is equal, the force bearing on the low pressure piston becomes greater and that on the high pressure piston less; hence, the position of the low pressure piston on the rod is of the greatest importance, and, in conscientious construction, demands that the low pressure cylinder shall be next to the frame for the purpose of better fastening and the superior opportunity carrying the large piston, which for security of fastening, must have the larger end of the rod.

The engine shown in the accompanying illustration has 28 inches high pressure and 30 inches low pressure, cylinders, with 18 inches stroke pistons, carries two wheels of 96 inches diameter by 25 inches face, weighing 10,000 lbs. each, giving a fly wheel capacity and efficiency equivalent to more than double their weight if made into a 20 foot wheel for a 60 inch stroke engine, making under ⅓ as many revolutions. It is being demonstrated in this plant that with a regulation giving an increase of speed of one per cent. from empty generators to full capacity, *i.e.*, 350 k.w., that the voltage taken at 480 when no current is being used, will follow the increase of engine speed almost exactly up to the maximum of 500 for full load.

ANGIER AND KENNARD.

THE above names have become in the last few months almost a household word in Chicago electrical circles, representing as they do several of the best rubber factories of the east. They have enjoyed a most flattering reception by the trade in the west. Mr. Angier and his partner Mr. Kennard are both young men who are well and favorably known to the trade and are nearly always "in it" when anything in rubber goods is wanted. The firm is established under most flattering circumstances, with ample capital, wide acquaintance and a thorough knowledge of the business engaged in. They are very desirably located on the fifth floor of the Monadnock office building.

NEW KESTER ATWOOD ARC LAMP.

THE A. H. ATWOOD ELECTRIC & MANUFACTURING COMPANY are just putting on the market a most desirable arc lamp, made for use in connection with every known system of electric lighting. The mechanism of the lamp is simplicity itself. It is not exactly an ornamental lamp in a general sense, but is very handsomely made and suggests many features which make it desirable for lighting stores, etc. These lamps may be operated on any incandescent circuit in connection with lamps of from 50 to 100 volts. The lamp will be shown at the convention by Mr. J. F. Kester, and should be seen by all interested.

WESTERN NOTES.

THE ELECTRIC APPLIANCE COMPANY report that business is already beginning to open up on the Meston alternating current fan motor, and that they have already closed a number of agency arrangements and entered some very large orders for fan motors. The Meston motor is so well known that applications come in from every part of the country, and the Electric Appliance Company plan to have a good live agency thoroughly established in every large town having an alternating plant before the fan season opens up. This agency is a valuable one and the applications are numerous.

INTERIOR CONDUIT has been very active during the past week, several of the larger buildings in Chicago being equipped with this well-known system. Mr. Romaine Mace, the representative of the company is in the city and makes his headquarters with the General Western agents, the Central Electric Company, giving them the benefit of his experience and untiring energy, in taking care of the present heavy business and laying plans for more enlarged development.

CAPTAIN JOHN A. GRIER, whose face has long been known in western electrical circles, has recently become associated with The Ansonia Electric Company, (formerly the Electrical Supply Company) and is at present at the Helios factory in Philadelphia, where he is familiarizing himself in every detail with the Helios Arc Lamp for alternating circuits, with a view of introducing it to the western trade.

OKONITE WIRE has been specified for the Congress Hotel, the new annex to the Auditorium. Okonite wire was selected purely upon its merits as an insulator over all other competitors, the Auditorium having had a varied experience with other wires, and a practical demonstration of the superior merits of the lasting qualities of Okonite.

THE RIEHLE BROS. TESTING MACHINE COMPANY announce that, beginning April 1, Mr. J. R. Matlack, Jr., will act as its representative at the World's Columbian Exposition, Chicago, and can be found, previous to the opening of the Exposition, at the office of R. W. Hunt & Co., The Rookery, Chicago.

MR. J. E. ZEUBLIN, acting general superintendent, has been appointed general superintendent of the Chicago Telephone Co. His office will be at Room 21, Telephone Building, 203 Washington street, Chicago.

MR. C. E. BROWN of the Central Electric Company has just returned from a very successful trip, both in the way of orders and expressions of good will from the Central's customers, whom he visited.

A. M. MORSE, better known as the "Buckeye Engine" man, called at this office on Saturday last. Mr. Morse is located in the Commercial Building, St. Louis. He reports the engine business good.

NEW YORK NOTES.

THE AUBURN ELECTRIC MOTOR COMPANY has been incorporated with a capital stock of $50,000, and the following officers chosen: Chas. H. Lucas, president; J. P. Hutchinson, secretary and treasurer. Directors: Chas. H. Lucas, Walter F. Brown, Henry J. Davis and J. P. Hutchinson. Chas. H. Lucas is also superintendent of the mechanical department and Walter F. Brown is electrician and superintendent of the electrical department. A general electric business will be done. The company has already bought a large building for a factory, with sufficient land for future enlargement, if required.

DIEHL & COMPANY, at No. 385 Broadway, are entering the field for the coming season fully equipped with an extensive stock of their electric floor column, propeller, and their specialty, the "Diehl" ceiling fans. Each fan contains its own motor, thereby obviating the necessity of shafting and belting. This, in connection with its thorough reliability and the fact that it is highly ornamental and is installed without disfigurement of the finest apartment, accounts for the enviable position it holds in the trade to-day.

CARPENTER RHEOSTATS. The new catalogue of the Carpenter Enamel Rheostat Co., of Bridgeport, Conn., is an exceedingly well printed pamphlet, setting forth in clear and concise manner the merits of this ingenious apparatus. Mr. Chas. D. Shain, of 136 Liberty Street, the general selling agent of the company, is to be congratulated on the way in which the rheostats have taken hold of the electrical public.

THE NATIONAL INDIA RUBBER COMPANY, of Bristol, R. I., makers of "N. I. R." insulated wires and cables have opened a branch-office at 487 Broadway, New York City, with Mr. H. L. Burdick as manager. Their wires have been approved by the Fire Underwriters Association, of New York, Boston and Chicago, and orders for large quantities are constantly reported from all parts of the country.

MESSRS. J. JONES & SON, of 39 Vesey Street, this city, have issued a very compact catalogue of forty pages descriptive of their annunciators, call bells, batteries, burglar alarms and other electric appliances. This firm also make a specialty of gas lighting apparatus, which they manufacture in great variety.

THE E. G. BERNARD COMPANY, Troy, N. Y., will remove May 1 to larger and more convenient quarters, at No. 43 Fourth Street, where they will have a much larger store and office. The growth of their business renders these increased facilities highly necessary.

W. S. CHESLEY & CO., of 24 Morris street, Jersey City, N. J., desire to hear from brass and copper companies in regard to lamp parts, commutators, segments and everything used in repairing apparatus.

MR. A. E. SCOULLAR, general superintendent of the New York Brush Illuminating Company, for many years, has resigned his position to engage in business outside electricity. His old associates have presented him with a very handsome testimonial.

ST. LOUIS NOTES.

THE ELECTRIC SELECTOR AND SIGNAL COMPANY will have an exhibit at the St. Louis Convention that should be peculiarly interesting to all electric light men. This exhibit will consist of the Company's system of selective arc light and motor cut-outs. Some new devices have lately been added to the system which materially simplify the operation of the cut-outs; these will be shown for the first time to the electrical profession at the Convention.

The Company will be represented at St. Louis by Messrs. C. P. MacKie, Robb MacKie, S. S. Bogart and Herbert Laws Webb.

THE SOUTHERN ELECTRICAL SUPPLY COMPANY of St. Louis report very brisk sales of Interior Conduit and Okonite wire in their territory. The following buildings are the latest to be equipped with the Interior Conduit system throughout: Rialto Building, Mercantile Club, St. Nicholas Hotel, Security Building, Planters Hotel, Union Trust Building, Polytechnical School Building.

THE ELECTRIC APPLIANCE COMPANY takes pleasure in informing their friends and announcing to the trade generally, that they have taken the Western Agency for the celebrated "O. K." weatherproof house, line and feeder wires, and will carry a large and complete stock in Chicago. The quality of the "O. K." products are too well known to call for any extended comment.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XV. MARCH 8, 1893. No. 253.

CARBORUNDUM:—ITS MANUFACTURE AND USE.

BY

E. G. Acheson.

SHOULD the reader ever have paused to give the subject a thought, he must have been struck by the wonderfully simple process employed by nature in the construction of her waterways, the leveling of the high and the filling of the low places, the cutting down of the great rocks, and the polishing and beautifying of the small pebbles of the beach. Has it ever occurred to him that man has appropriated this same agency for the building up of what we call civilization? If so, he must, now realize the immense value of this process, and if not, he must, at a simple suggestion, admit the all-important part in the work of nature and man, of *abrasion*. Not a tool, nor an article made by means of a tool, would we possess did we not employ abrasion during some part of its manufacture. It is the most universally employed of all processes. The act of abraiding being so all-important, of what immense value to man, then, must the best abrasive material be!

A complete list of natural abrasives would, probably, include all of the known rocks and earths. Many of them are, however, of little value, and for industrial uses, not more than ten or twelve are made used of. These are selected on account of their efficiency or their liberal supply and consequent cheapness. Those we find most ordinarily used are, diamond or crystalline carbon, sapphire, ruby, corundum, emery, rotton stone, and rouge. Since the beginning of time man has known of nothing superior, or equal, to the diamond as an agent of abrasion, and it is now used in a crushed or powdered form for the abrasion of hard substances, when the value of the completed articles justifies the use of an agent so costly.

The above abrasives are used in the order named, as the work is more or less hard to perform, or as its degree of perfection requires, restricted by the cost of the abraident and labor. Thus, the costly diamond and sapphire are, in the machine-shops, factories and mills, replaced by the cheap corundum and emery, as the cost of the former would more than balance the increased labor and time required with the latter. It is therefore easy to realize how great a boon to the manufacturing industries would be a material having the extreme hardness of the diamond and the cost of corundum; such a substitute we find in "carborundum," its very name encompassing those two important abrasives.

Carborundum (from carbon and corundum) is a new material, both to chemistry and the mechanical industries. It is a purely manufactured article and marks another triumph for electricity in the domain of chemical industries—another illustration of this invisible agent, guided by man's hand, tearing apart the closely united elements joined by nature, and re-arranging them for his industrial uses. It is composed of carbon and silicon in the proportion of one atom of each to a molecule, the chemical formula being SiC.

The process by which carborundum is produced, is one of more than ordinary simplicity. It consists of the introduction of an intimate mixture of carbon and sand into an oblong box of bricks or clay, into each end of which project one or more rods, or electrodes, of carbon, and through these rods of carbon and the mixture of carbon and sand, passing a current of electricity of a sufficient quantity, and for the proper length of time, to fuse the mass and cause the reduction of the contained silicon and its subsequent combination with a portion of the carbon.

The accompaning illustration, Fig. 1, shows one of the earlier forms of carborundum furnace, with the attendant furnaceman and instruments for regulating the electric current.

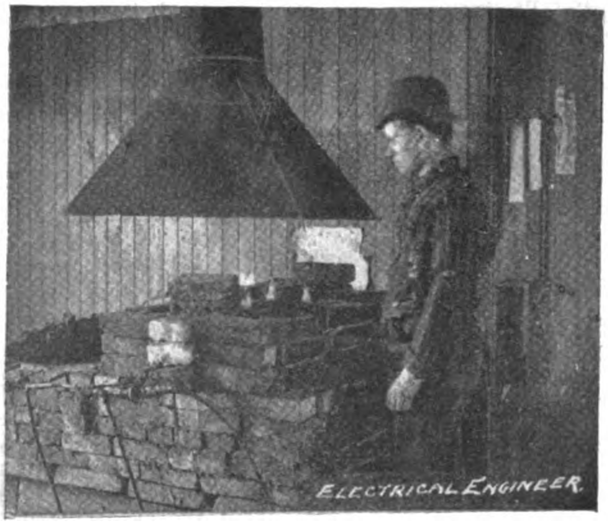


FIG. 1.—EARLY FORM OF CARBORUNDUM FURNACE.

The crude simplicity of the furance is probably its most striking feature. The company have now under construction, three furnaces having a united daily capacity of five hundred pounds.

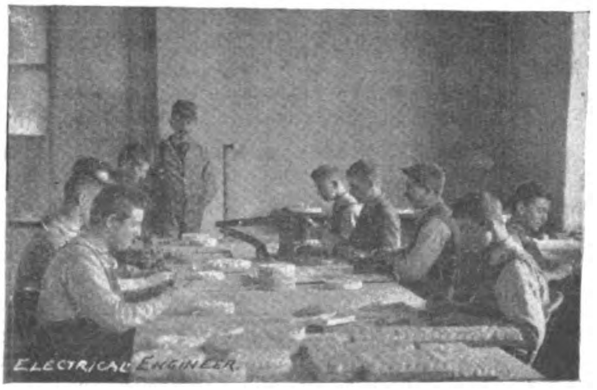
Upon removal from the furnace the carborundum is in the form of a porous cinder-like mass, consisting of crystals of various sizes. This mass is first washed in water, then treated with acid to remove soluble impurities, again washed, then dried and crushed. The crushing breaks apart the individual crystals and these are then separated into the commercial sizes or degrees of fineness. This separation is now done by the ordinary sifting process; that method will, however, soon be replaced by a more perfect arrangement, consisting of a series of tanks through which flows a continuous stream of water, the sizes of the tanks increasing in the direction in which the water flows, and the sizes of the crystals deposited being in the reverse order, that is, the larger in the first or smaller tank and the smaller crystals in the last or larger tank.

The first commercial use to which carborundum was put was the cutting and polishing of diamonds, a class of work never before accomplished by any abrasive other than the natural crystalline carbon or diamond. Tradition, supported by the state of the art, required a diamond to cut a diamond, and "Diamond cut diamond" arose as a mighty Sphinx in the pathway of carborundum in the diamond-cutting industry. The diamond cutters, with the exception of a very few, would not admit the possibility of manufacturing a material that would cut diamond, and asserted that carborundum was not sufficiently hard to perform the work required. The writer, however, has stood for hours, and at various times, by a diamond cutter's lap and watched the cutting and polishing of diamonds by means of carborundum.

Notwithstanding these difficulties, some small quantity was sold for diamond and lapidary work both in this country and Europe, an agent having gone over to Holland for the purpose of introducing it into the Amsterdam diamond-cutting works. In the meantime improvements were made in the process of manufacture, and a greatly increased output was obtained. In June, 1891, a stock company, under the title of the Carborundum Company, was organized for its manufacture, the price greatly reduced and the attention of brass manufacturers and metal workers called to its superiority over emery in grinding valves, etc. The amount of business developed in the diamond industries was so small that the company ceased to push it and devoted its attention to the other industries. In June, 1892, still further improvements were made, resulting in increasing the production to 25 pounds per day, and the company again lowered the price to $2.00 and $4.00 per pound, depending on the quantity purchased.

During these months many experiments were made in the manufacture of wheels, hones, and other articles or forms in which abrasives were used. These experiments terminated in, or led to, the construction of a kiln as used in the more improved processes of pottery manufacture. The kiln was first fired on Sept. 20, 1892, and it is with much personal pleasure the writer states that from the date of that firing the business of the company has been phenomenal. The company are now adding an extensive addition to their plant and expect in thirty days to be manufacturing five hundred pounds of carborundum per day.

The Carborundum Company at present occupies a portion of the premises of the Monongahela (Pa.) Electric Light Company and from them it obtains the electric current used in the formation of carborundum. The present plant of the light company is 75 h. p., and with the additions now under construction they will have a total capacity of 300 h. p. It is probable that the Carborundum Company will, during this year, start the construction of an extensive plant for their own use.



ELECTRICAL ENGINEER.

FIG. 2.—MOLDING SMALL CARBORUNDUM WHEELS.

The completion of the kiln produced a decided change in the business of the company. It was quickly found that a wheel of carborundum properly constructed was a very superior tool for the cutting of glass, porcelain, steel, and similar hard substances. Extensive and prolonged experiments were made for determining the best material for binding together the carborundum, and as a result a series of bonds have been adopted, each having peculiar advantages for some specific kind of work. It was also found that the percentage of bonding material used in the wheels should be varied for the different kinds of work to be done.

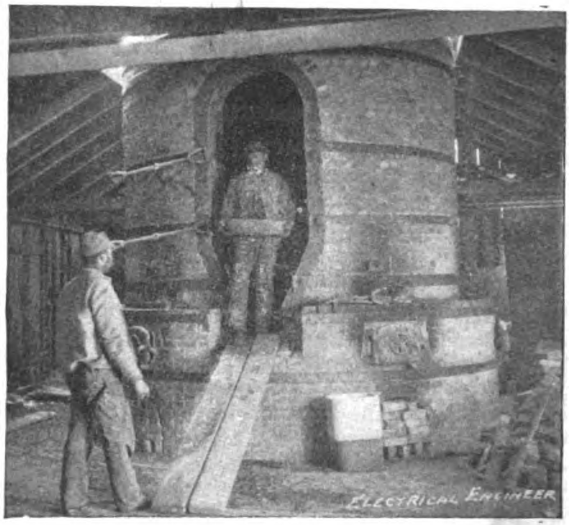


FIG. 3.—REMOVING "SAGGERS" FROM THE KILN.

The Westinghouse Electric and Manufacturing Company, of Pittsburgh, Pa., are using carborundum in wheels and grains for the grinding-in of the stoppers of their new lamp, their present consumption amounting to several thousand wheels per month.

In the early part of January of this year, carborundum in small wheels, discs and points, was introduced into dentistry, as a substitute for the emery heretofore used. It was received in a very flattering manner, amounting to almost enthusiasm, on the part of dentists, many of them stating that the wheels were equal, in rapidity of cutting, to the diamond discs used by them.

For wheels, hones and other manufactured articles requiring a hard binding material, the carborundum, in the appropriate degree of fineness for the desired article, is placed in the hands of a workman who mixes it with a predetermined percentage of binding materials, after which it is ready for molding or pressing into the required forms. Our engraving, Fig. 2, illustrates the molding of the dental wheels, discs and points and the small wheels used for the Westinghouse lamps. As these wheels are made, they are placed on little blocks of burnt clay, called "bats," the upper surface of the "bat" being a counterpart of the wheel it supports. The little "bats," with the wheels they support, are themselves placed upon larger "bats" and the whole set in clay boxes called "saggers," and these are carried into the kiln and there piled in columns. When a sufficient number of these are placed in the kiln, the door of the latter is built up with bricks and the fires lighted. The heat is increased slowly, through a period of about 30 hours, careful watch being kept for the fusing point of the bonding material. This fusing point is determined by means of little test pieces, which are withdrawn from the kiln, at frequent intervals, through small holes or windows, made in the sides of the kiln for that purpose. When the bond starts to melt, the temperature is held constant for some hours, and then permitted to fall, the whole operation requiring from 60 to 80 hours. The kiln having cooled sufficiently, the door is opened and the "saggers" containing the finished product are removed. The removal of the saggers is shown in the illustration, Fig. 3.

In the manufacture of wheels for machine work, the materials are taken from the mixer to a workman who weighs out the required amount for the wheel desired; this is placed in a steel mold and together they are introduced into a hydraulic press, where the desired pressure is applied —this pressure varying from one to 100 tons, depending upon the size of the wheel being made. This operation of filling a mold and introducing it into a 100-ton press is shown in Fig. 4. When the mold is removed from the press, it is opened and the formed wheel placed upon a "bat" and then in a "sagger" and treated as in the case of the small wheels.

It was probably to be expected that a material composed of the elements entering into carborundum, would have many interesting and useful applications. That this is the case, has even now been demonstrated. It would be difficult to think of a more novel use for it than its introduction into the electric lamp, as the light-giving body. [Carborundum formed into buttons and mounted in lamp bulbs was exhibited by Mr. Nikola Tesla before the Institution of Electrical Engineers in London in February, 1892. While the future use of carborundum for this purpose is, as yet, problematical, Mr. Tesla has already accomplished very much towards the perfecting of his system of lighting, embodying within its details the use of lamps, depending upon this remarkable material for the transmutation of electric waves into light waves. The chemist also will find in carborundum a new reagent, which the future may prove to be of unusual value.

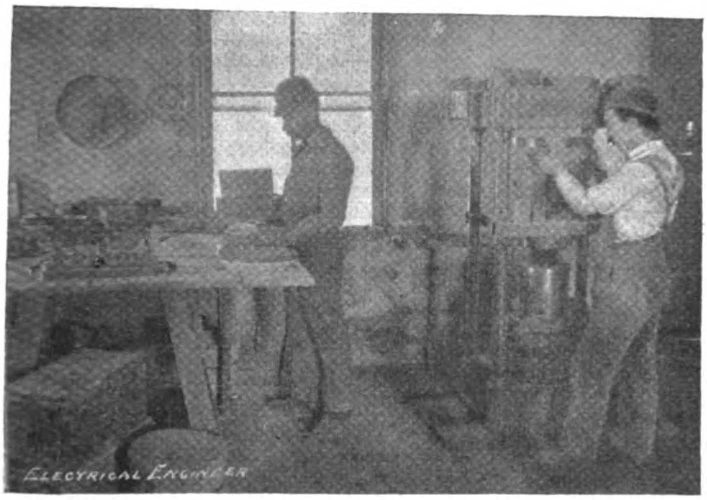

FIG. 4.—FILLING AND PRESSING THE MOLDS.

The Carborundum Company are now arranging an attractive exhibit of their crude and manufactured materials, for the World's Columbian Exhibition, having been allotted 250 square feet of space in the Mines and Mining Building.

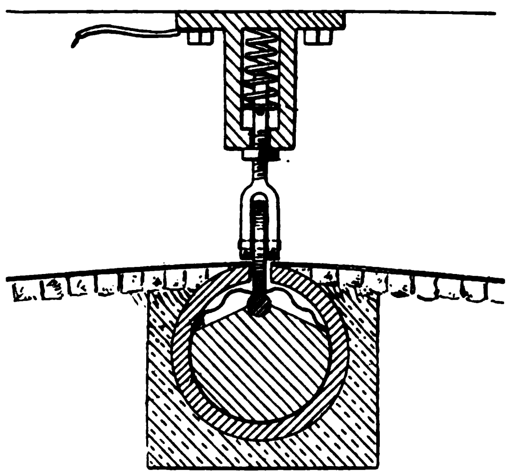
WORLD'S FAIR BRIEFS.

MR. Frederick Sargent, mechanical and electrical engineer of the Columbian Exposition, has been promoted to a position in which he will have several assistants to perform under him the work of the department. The work has been divided into two sections. The mechanical engineering section will be in charge of Mr. Richard Pierce. Mr. Sargent will remain at the head of the two divisions and direct the work of both.

The World's Fair grounds and buildings have a combined water capacity of 54,000,000 gallons a day, and will soon have 100,000,000. There are 25 miles of water mains and 291 hydrants, and a hundred more will be provided. There are three steam fire engines, four chemical engines, a ladder truck, water tower, 40 hose carts, 26,750 feet of hose, 1,050 hand fire extinguishers, 2,500 fire pails, a steam fire boat, 65 firemen, 150 alarm boxes, 150 patrol telephones, 500 guards and complete electric light and sewerage systems.

THE PERKINS ELASTIC RAILWAY CONDUIT.

AMONG the many and various conduits for electric street railways, that recently designed by Mr. F. C. Perkins, of Buffalo, N. Y., possesses the merit of simplicity and cheapness of construction. The accompanying illustration clearly shows the principle involved. The bare conductor is mounted on a stringer of wood impregnated with oil, or some other insulating substance, and entirely surrounded by a flexible metallic tube. The current collector carried by the car presses this tube downward, making contact with the conductor and completing the circuit. The conductor is thus absolutely protected from water, mud, etc., and perfect insulation maintained.



THE PERKINS ELASTIC RAILWAY CONDUIT.

THE ARMOUR INSTITUTE, CHICAGO.

WITH the University and Mr. P. D. Armour's latest gift, the Armour Institute, Chicago, seems destined to become noted for scientific as well as commercial enterprise. The building has been under construction for four years, and no one, except a few directly interested, knew of its purpose. The Institute is on the corner of 33d street and Armour avenue, being pleasantly situated in the residence portion of the city.

The building has four floors with a basement, and a power-house attached. It is built of brown stone and pressed brick, and the interior finished in white marble, The power plant is nearly completed, and consists of two Stirling water tube boilers and a 200 h. p. Hamilton-Corliss engine, which can be run either condensing or non-condencing. Rope transmission will be used to connect the engine with the line of counter-shafting. Four dynamos will be attached to this line by friction clutches. The dynamos will be both alternating and direct. Two will be used for lighting, one for power, and the fourth for experimental purposes. All the machinery in the laboratories will be operated by motors.

In the basement there are rooms for wood working, founding, forging and drafting, and several store and tool rooms. On the first floor, there will be a mechanical laboratory and machine shop, the office of the President and the general library. The second floor is devoted to the departments of electricity, chemistry and physics, each with ample laboratories and lecture rooms.

There will be fourteen more or less distinct departments, but the aim of the Institute is to become a technical school of the highest grade. The technical courses will be in mechanical and electrical engineering, physics and chemistry. A department of fine arts and architecture is contemplated. In addition, there is a school for librarians and a department of domestic science.

The faculty, as now organized, includes four professors, four directors of departments, four instructors, two assistants and an engineer. It is intended to equip each department with the best apparatus obtainable, so that unsurpassed facilities for instruction and investigation will be offered.

The appointments for the scientific faculty are, Victor C. Alderson, of Chicago, professor of mathematics; James C. Foye, of Lawrence University, professor of chemistry; Wilbur M. Stine, of the Ohio University, professor of Electrical Engineering; W. H. Runyon, of Chicago University, instructor in physics; E. W. Cooke, of Chicago, director of School of Mechanical Engineering.

The library system of the Institute is expected to be of especial value. Each laboratory will be provided with a complete technical library, and in addition, there will be a general library, of literary, historical and scientific works.

SOME EXPERIENCES WITH THE ALTERNATING SYSTEM.[1]

BY R. H. STERLING.

OUR company was among the first to install a large alternating plant—the largest, I believe, at the time in the United States. How wise we were in doing so I will answer by pointing to the enormous growth and success from the start of alternating current lighting, and its finally being fostered by those who were at first its bitterest enemies. We did experiment some, I will admit. A few minor details in apparatus did not just meet the requirements for practical use; but our parent company has always been willing to adopt the suggestions of its users and remedy defects discovered by them—a plan, by the way, which should be followed by all who manufacture apparatus—for the central station men are those who are best able to judge its merits and criticise it from all sides.

I will now take the principal features of an alternating station in detail, describing what have been our results and the best practice in my experience. I will begin with the switchboard. A circuit board is eminently better made of marble, as a matter of both safety, durability and appearence, and should have plenty of space between it and the wall. The dynamo bus wires should run in horizontal rows on the back, with plug holes extending through to the front, to connect to either side of each changing switch. There is a changing switch, of course, for each feeder or circuit, and all bus wires can be connected to any particular feeder. The front of the board should be divided into perpendicular panels, each panel representing a feeder.

On the back there will be the converter for voltmeter, compensating devices, etc., and the fuse blocks. These are preferably placed on the back, as it is an unpleasant thing to have a fuse blow in a man's face, and they should not be so high on the board that they cannot be reached standing on the floor. Many of you, undoubtedly, have had trouble with a fuse arcing, and finally melting the fuse block into a conglomerate mass, or setting fire to the switchboard. There are two simple remedies for overcoming this; one is to have all fuses covered with a piece of asbestos paper rolled around the fuse wire or link in the form of a tube, a little larger on the inside diameter than the wire, to allow for radiation of heat, so that the fuse will not melt under its rated capacity. These asbestos tubes are very easily made, and can be pasted either with shellac or silicate of soda, which is preferable, the idea being that when a fuse is blown, the pent-up gases in the tube are forced out at either end so violently that the resulting arc is dissipated immediately. I believe I am not the originator of this idea, but believe we can claim the use of asbestos as our own, and which is the only substance that is practicable.

Another simple plan to prevent arcing is to have all fuse blocks placed on a narrow shelf, with their faces up, as there is always a tendency in an arc to take an upward direction, owing to the current of heated air resulting from it, and in taking this direction there is a natural pulling away of the arc from the two metallic portions of the fuse block. Fuse wire as now made is quite reliable as to its carrying capacity, but, like many other good things, is not trustworthy, if abused. A lead fuse, either wire or flat link, should never be screwed down under a screw head and washer, no matter how small the carrying capacity it is intended for. This may do for a short time, but the soft metal soon loosens up, a poor contact is formed, and the fuse melts from the heat thus generated, causing no end of annoyance. This applies to the fuses, no matter where they are used, all over the circuit. The one way out of this is a small flat copper terminal, slotted to slide under the screw head, and soldered to each end of the fuse wire. The carrying capacity of the wire can be stamped on one terminal. These are cheaply made. A boy with a punch and die can stamp out many hundreds of them in a day, and the soldering, with a little experience, is rapidly accomplished. Had we adopted these fuses when we first began to furnish light, five years ago, and insisted on all inside wiring being fused in this manner, we should have been many dollars ahead to-day, and there would have been fewer lights out during that time.

Nine-tenths of the calls on our complaint book show a record of fuses blown in branch or main blocks of inside wiring, which we have to send men out to replace, and from repeated inquiries from these men, I find that this same proportion of nine-tenths would hold good for fuses that had blown or rather melted from poor contact, due to lead becoming loose under screw heads, and from no cause of short-circuits, overloading or trouble in the wiring. We now compel all wiring contractors to use a copper terminal fuse, and we ourselves replace all blown-out ones with this style; but with seventy-five thousand lights connected up, we do not see our way clear to weeding out the old fuses just at present; so let this be a warning to those young in the business.

On the front of the switch-board we have for one section or panel a volt and ampere meter for every feeder, one over the other, and surmounting these a pilot lamp run from the converter supplying the voltmeter, whose primary should be tapped on the feeder wires above the fuse block so that should a fuse go out quietly, as is generally the case when fuses are arranged in the manner I have mentioned, the attendant's attention will be called to the fact by the extinguishing of the pilot lamp. The changing switch, generally placed on the front of the board for each feeder, should be about breast high, so as to be easily reached to make a quick throw. I say usually placed on the front of the board, as it is only recently that a new switch has come out that has its jaws and contacts so arranged that it can be placed on the rear of the panel, with the lever extending through a slot to the front of the board. This is a matter of great safety to the switch tender, for, as stations increase in size and load, a new element of danger sometimes manifests itself in the act of throwing these changing switches. A violent arc is formed which follows across from one set of contacts to the other, throwing two dynamos in multiple through the medium of this arc, burning the attendant's face and hands and sometimes wrecking an armature, as, of course the two dynamos are not apt to be in synchronism when thus thrown together. Placing the switches horizontally will lessen greatly the continuance of this arc, on the same principle that I have mentioned the placing of fuse blocks on the switchboard with their faces up, and a fibre or slate partition between the jaws will prevent the arc short-circuiting the dynamo. This annoyance is only met with on feeders of considerable length and those having a large number of converters on them. It is due to the inductive discharge from converters and line, and is similar to the extra current or field discharge of a dynamo. Its occurrence depends largely upon the period in the wave phase at which the circuit is opened, and is proportional to the length of the circuit and the number of converters connected on the line. I have found this discharge to occur more frequently on circuits whose converters were partially loaded. This would naturally seem to be the result when the secondary coils of the converters were exerting no action on the primary, but I have had the most severe arcing on circuits with heavy loads. The damaging result of these arcs, however, has been entirely overcome since placing the switches horizontally, as I have described.

I have spoken only of the feeder ammeters. There should, of course, be an amperemeter for each dynamo. These are preferably placed together in a group at one end of the board, so that at a glance the attendant can see what load he is carrying, or on what dynamo there remains room for more feeders as the load comes on or goes off. The regulators and rheostats can be placed at the base of the switchboard, or, much better, if there is room, in a compact row out in front of the board about four feet, on a strong framing of wood or iron, so that all the voltmeters can be watched at the same time that the adjusting of the pressure is taking place. This saves the annoyance of the attendant jumping from the rheostat out to the front to catch a glimpse of the voltmeters to see how near he has come to guessing at the right amount of resistance he should have thrown in or out. The result will be far better service if the rheosats are thus arranged.

This now brings us up to the remaining feature of the switchboard—the lightning arrester—though I cannot say that, necessary as this last-named appliance is, the switchboard is the all important place for it. There may, however, be a lightning arrester on each side of every feeder, placed in a row on the top of the board, or on the wall back of it, and a heavy copper wire running along past this row and connected to each arrester with a tap wire, and the main wire leading to a good ground in as straight a path and with as few crooks and turns as possible, as every bend offers a source of self-induction detrimental to the flow of the lightning discharge. The source of ground cannot be too perfect; have several of them radiating off to different points, to a mass of metal in a well, or soldered to a water main, so, should one fail, the other may be relied upon. The lightning arrester itself should be an instrument devoid of fuses, capable of rupturing instantly the arc is formed, and still remain set for a second discharge; should be free from all moving parts; not absorb energy, and should be so reliable and substantial that it could be set up anywhere on the line and forgotten, and still perform its duty. This may seem to you like an ideal instrument, but, so far as alternating currents are concerned, I am positive that this state of perfection has been attained in a certain arrester now on the market. There is no question about the efficacy of lightning arresters placed out on the line, if we wish to keep the lightning out of the station and protect our converters, especially in districts remote from other wires and tall buildings, as in the residence portion of a town. It is a good plan to place one at the end of each feeder and branch main, and scattered at intervals midway on the circuit; they also are a wise protection over a large bank of transformers, notwithstanding the fact that we are taught to believe that lightning abhors an inductive resistance as nature does a vacuum, and that a collection of such resistance would be self-protection, yet it does not prevent the discharge entering the case of the converter; then it does not have to jump much more than the space of one-eighth of an inch over to the plates to ignore these inductive coils, reach the secondary outlets, and thence to the house wiring, when it generally finds an easy path to earth with the close proximity of inside wires to gas and water pipes, and especially on combination fixtures with poor insulating joints. This does not always completely burn out the converter, as oftentimes this discharge has only ruptured the primary coils on the first turn of the wire at the point where it has jumped to the frame holding the plates, and is easily repaired. I imagine this is the case when a discharge takes place when there is no dynamo current on the lines; at other times there is a complete destruction of both coils. In a great many instances we have traced converters burned out by lightning to defective insulation in the house wiring. Whether the ground actually existed before the disruptive discharge, or was caused by it, we could not always tell. I did find one place where the wire was fused to a gas pipe up in the attic, the discharge evidently having jumped through the insulation, as the wire had been carelessly left resting on the pipe. Of course, the primary fuse, having blown in the burning out of the converter, did not leave the circuit permanently grounded. We do not want the house wiring a safety valve to relieve the circuits of their static charges, therefore, having lightning arresters, plenty of them, that will offer an easier path to earth across small arcing gaps, smaller than can be found in the converters; but no matter how perfect the arrester is, it is valueless unless it has a good ground connection and a straight copper wire, not smaller than No. 6, without bends or turns, connecting the two. A very convenient method I have found to make a reliable earth connection for arresters out on the lines, is to dig a hole at the foot of the pole about two feet in diameter, three feet deep, and driving down through it a twelve-foot length of 1¼ inch galvanized iron pipe, having on the lower end a driven-well point to allow it to be driven easily, and a cap screwed on the upper end to prevent the sledge hammer splitting the pipe. The No. 6 wire can be more thoroughly soldered to the pipe before it is sunk.

---

[1] Abstract of a Paper read before the National Electric Light Association, St. Louis, Mo., February 28 to March 2, 1893.

The upper end should be driven to about one foot below the surface, and the hole filled in with finely broken coke, which increases the conducting surface at that part of the earth that is the dryest, and the lower end of a twelve-foot pipe will usually be in moist earth, and can be relied on to furnish a good connection at all times. I once had an electric light man tell me that he considered a small coil of wire buried just under the surface of the earth sufficient grounding, as the rain would immediately soak the earth and make all the ground he wanted. I have observed severe lightning discharges that took place before a drop of rain had fallen.

While on the subject of the burning out of converters, I will mention an annoyance we sometimes meet with in a primary fuse blowing, arcing and welding the leading-in wires to the case, or so carbonizing the fuse box that a short-circuit is formed on the line. This will always be the case where the fuse carrying a high potential current blows in a pent-up space, with no chance for the gases to escape. The arc is being fed, and increases until a fuse is blown at the station and shuts off the supply of current. Generally, on throwing in this feeder again, after replacing the station fuse, it will be found to work all right if the wires are not fused to the converter case, or everything is not carbonized inside. We have in some instances, on its again blowing the station fuse, fused up a little heavier and finally removed the trouble, not fusing to that extent that it would wreck the armature. We are learning now that it is far preferable to have no primary fuses in the converter case, but a large primary fuse and switch box combined, removed from the converter to protect it. We have long since discarded secondary fuses in converters, replacing them with copper wire; and let me remark here that this is what a member of this Association meant when he made the statement before one of its conventions that we had been substituting copper wire for all our primary fuses, he evidently mistaking the primary for the secondary end of a converter. This would also be a sad mistake to make when fooling with hornets.

This short-circuiting of the line by the burning out of converter fuses and other causes led me to adopt a combined switch and fuse box on all branch lines leading from the main feeders, and we have found them of immense benefit. The switch cuts off all connection from the line wires in fusing up, and also makes a convenient means of disconnecting that part of the circuit to locate grounds and other trouble. Then the greatest advantage is their blowing when there is a short-circuit on the branch they protect, thus preventing every light on the rest of the circuit going out by the station fuse blowing. Then, again, it locates at once where the trouble lies by sifting it down to one of, say, twenty branch mains, by telephone calls pouring in that lights are out at such a place.

As alternating stations increase in size and larger units of dynamos are adopted—which is certainly a very wise step towards economy—another class of appliances is required at the switchboard, namely, devices for independently regulating the state of pressure on any particular feeder, the dynamo pressure remaining the same. The necessity of this can readily be seen, for we will have, say, on the same dynamo, when it is of large capacity, several feeders of different loads; those carrying the greatest number of amperes requiring a higher electromotive force to overcome the drop on line, so that if this required pressure all came from one source, these feeders of lighter load would be receiving to much potential, and a large lamp breakage would be the result. Therefore, the potential of the dynamo is regulated for the lighter feeders, and pressure raisers or "boosters" used to bring up the potential still higher for the remaining feeders. The principle of these regulators is this: If we take a converter whose capacity equals the maximum load of the circuit and connect the secondary in series with one side of the feeder, and the primary across the two sides, we are then adding the fifty volts of the secondary of the converter to the 1,000 volts of the line, raising its initial pressure five per cent. Adding a number of these in series in like manner, and having a suitable switch to throw them in or out in succession, makes a very convenient means of raising the voltage, but resembles somewhat, as I once heard it remarked, a man raising himself up by his boot straps. I have sometimes found it very useful connecting in ordinary converters at the switchboard, for temporary heavy loads, in this manner, where feeders were not provided with the regular "boosters."

Reactive or choking coils may be employed instead of "boosters," with the same end in view—*i. e.*, the proper adjustment of pressure on feeders of unequal drop supplied from one source—only in their use they will be placed on the lighter feeders and the dynamo be made to raise the E. M. F. for those having the heavier load. The first cost, I think, would be in favor of the reactive coils, but the relative economy in energy consumed would be slightly in favor of the pressure raisers.

A serious annoyance is often met with on the line from the inductive effects of two parallel circuits upon each other, causing the lights to waver, or "pump," which better expresses it. When this trouble first manifests itself in a station, the engine is generally the first thing to be blamed, and the engineer is caused many sleepless nights or days in trying to remedy it. We seldom find this effect in small stations, unless the feeders are parallel to each other for a considerable distance. It is most marked in circuits that are parallel and one of them carrying a heavy load, which exerts this inductive influence on neighboring lines on the same principle as the primary coils of a converter inducing currents in the secondary parallel to it; only in the case of this action on the lines, where each line is fed from a separate dynamo their phases, of course, not corresponding, we have in this cross-induction a very unsteady action in the current. Annoying as this trouble is, it is one of the easiest to remedy. First, see if some combination on the switchboard will not bring about a change in affairs. Ascertain if the several lines on which this trouble is noticed cannot be all run on the same dynamo; but if this should cause this induction to appear on other circuits formerly free from it, then the remaining way is to transpose the circuits midway between the starting point and where they cease to run parallel, by inserting a break arm in each side of the line, and joining in the shape of a cross the four ends thus formed. This will neutralize and break up the trouble completely.

These topics I have touched in my paper have been chosen as those most interesting and worthy of discussion, and with the hope that they will be of benefit to some of you, and call to mind other experiences I have not mentioned, which, if given freely before a body of this nature, will help bring about the results we are all striving for—good service and dividends.

MORALS OF CORPORATIONS.[1]

BY E. A. ARMSTRONG.

A CORPORATION is best defined by saying it is an artificial person, possessing certain limited rights, powers and privileges with a life, varying in each case from a few years to perpetual existence.

That there is a popular distrust, if not actual hatred, of corporations as such is undoubtedly true. I suppose a myriad of causes may be found and properly credited as the source of this.

A corporation of to-day, however, is vastly different from those not half a century old. In most of the States I apprehend their creation is very similar to that of my own State, New Jersey. With us corporations are formed under general laws passed for particular classes. A corporation may be formed for the desired purpose by making and filing articles of association setting forth the prescribed requisites. When this is done, by operation of the law, a corporation is formed. For many purposes only three persons are required. There is no charter, no grant, no executive, legislative or judicial act required. To be sure I speak of the present. Before 1875 it was possible to obtain a special legislative act of incorporation. Now, a corporation being created this way, is it just or reasonable that it be condemned *per se*? I cannot think that it is, because the inherited antipathy is both unjust and unreasonable. It is not, nor can it properly be, a class condemnation even should individual cases merit it.

If in this age and this presence I should say that this country owes more to corporations than anything else, I don't know how I should be regarded. In some places I know that if I desired to retain as much popularity as any man ought to court, that is, enough to live peaceably beside his neighbor, I would not dare say it. But would it not be true? These same people who in one breath condemn corporations in the other deify co-operation. Crucify the doer and crown the deed. Co-operation has been, and in all probability will be, in all ages the panacea offered for most of the social ills of the time. We are wont to deprecate, and rightfully, too, I think, disjointed individual effort. Guerrilla warfare, while exasperating and annoying to the enemy, accomplishes very little. Less than a hundred organized, drilled and experienced men may readily put a thousand in a mob to flight. The same will hold good in economic and business relations.

---

[1] Abstract of a Paper read before the National Electric Light Association, St. Louis, February 28 to March 2, 1893.

If, then, so far I am right, the conclusion follows that a corporation is a desirable and a necessary thing to accomplish the greatest good with the least expenditure of energy and wealth. If what I have said does not prove that to your satisfaction, I shall want you, for the sake of my argument, to assume with me it to be proved, for I propose to so consider it. Now, then, comes my application, and I propose to consider it in two aspects. The first are the moral obligations *from* a corporation to the public, first, and then to the individuals composing the public. The second are the moral obligations *to* a corporation from the public, first, and then from individuals, as they can best be considered together. I shall not formally group or place these two headings, but run them right together. Nor do I propose to deal with corporations generally; but, as this is the National Electric Light Association, I propose to consider electric light companies particularly.

The quasi-public character of much of the business of almost every electric light company in its dealings with municipal authority must be emphasized. Every company doing such service occupies such a position of trust as to require it to give a maximum of service at a minimum of cost. Don't misunderstand me. It is not only the privilege of an electric light company to receive, it is its duty to demand fair compensation for what it provides and furnishes. It is just as dishonest for it to take advantage of its position and crowd the municipality as it is for the municipality to reverse the tables. We have often taken occasion to complain of the unfair treatment given companies by municipalities, but too often the treatment has been invited. When a corporation such as ours makes a large investment for public lighting, and while it continues to regard what I have indicated as its duty regarding service and charges, it has the right to expect a continuance of the municipal—patronage, I was about to say—service, I will substitute. Any deviation from this, while not a violation of an express, is the violation of an implied contract; something in law just as binding when defined, and, therefore surely ought to be in morals.

Such, briefly, is the way in which our corporations and our governments should regard each other, as I take it. Be mutually regardful of the duties and responsibilities of each other and properly regarding their reciprocal obligations. Each one can further carry out the argument to his satisfaction.

That there is, to a wonderful extent, this appreciation of obligation on the part of the companies is a thing very pleasant to contemplate. If accident or disaster happens to a company, just see what heroic effort is put forth to remedy it. Men and money are never spared. The inquiry is made, Can it be done? And if it be answered affirmatively, immediately comes the decree: Then do it. A notable instance of this, the latest of many coming under my observation, be it said, is that of the Buffalo plant. Our friend and former president, Mr. Huntley, worked with more than his accustomed vim and vigor to make his plant a Phœnix, and did it because his first desire was to serve his city. Say what you will, gentlemen, this is patriotism

It is the duty of our corporation to use the best methods it knows or can learn, adopt all the improvements, and render the best possible service, and that at as reasonable a figure as it can afford to do it, having a just appreciation of the risk the capital invested sustains, which is entitled to an adequate return, If you can furnish light or power at a less figure than you are now receiving, and still pay your stockholders a fair return, it is your bounden duty to voluntarily reduce your prices, so that those who make your business possible may have their share in your prosperity.

So far as I have been able to learn from observation, central station companies of themselves have been very considerate and mindful of each other. The poaching has been at a minimum. To be sure, I exclude from this entirely the *assisted* and *inspired* organizations that masquerade under the name of local companies. This amicable and creditable feeling is, as I take it, largely due to this association and to our electrical papers. The more people know and learn the more tolerant and less bigoted are they.

There is one branch of this subject I have not named, and that is the attitude of the parent and supply companies toward the companies of our association. They, of all people, ought to have regard for us. Indeed, they have in times past had the greatest regard for us, in fact, quite an *absorbing* regard.

I do not think that I ought to prolong this further. I only want to emphasize the fact that because men are associated in a corporation, and, therefore, lose some financial responsibility, they do not thereby lose also all moral responsibility.

As corporations we can do what as individuals would be impossible. The aggregation of the littles will accomplish wonders, just as brick after brick makes the tallest and grandest structure. But the beauty and the strength and, indeed, the utility of the world is absolutely dependent upon the perfection of the single one, the individual. Therefore, fellow stockholders and officers of corporations, in all these things "Be ye perfect."

WROUGHT VERSUS CAST IRON FOR FIELD MAGNET FRAMES.[1]

BY A. D. ADAMS.

THE aim in this paper is to point out some of the advantages of wrought iron over cast iron for the field magnet frames of bi-polar dynamos. The researches of Prof. Ewing and Dr. Hopkinson show that the same magnetizing force per unit of length, as measured in ampere turns, which produces in good hammered scrap iron a magnetization of 100,000 lines per square inch, produces in good gray cast iron only about 42,000 lines per square inch, and these values are about as high as we can go in either of these metals and get anything like a proportionate increase in magnetism for increase in magnetizing force. If, then, the same number of ampere turns are to be used for a given length of magnetic circuit, cast iron must be about two and a half times the section of wrought iron. Since the field magnet, to have the same magnetic carrying capacity at the same permeability, must have about two and a half times the section when made of cast as when made of wrought iron, the weight of cast iron for the same type and capacity of machine will be about two and a half times that of wrought.

In order to compare the relative amounts of copper required in field magnet windings for machines of the same capacity, but with different metals in the field magnet, the same wattage or exciting current must be assumed for all types. Take two machines of the same type and capacity, with the same length and section of air gap between the armature core and pole pieces and let one field magnet be made of wrought and the other of cast iron, throughout, each having the field magnet core circular in section and the area of the cast iron core two and one-half times that of wrought. Since the ampere turns required on each magnet are equal, also the watts expended in winding, there will be the same number of turns of wire on the cast iron as on the wrought iron field.

As the two field cores are circular in section and one two and a half times the area of the other, the length of wire required around the cast iron will be to that around the wrought iron core as $\sqrt{2\frac{1}{2}} : 1.$

Since the weight of copper required to transmit a given amount of electric energy at a given pressure and loss varies as the square of the distance, the weight of copper on the cast iron will be to the weight of copper on the wrought iron core as

$$(\sqrt{2\tfrac{1}{2}})^2 : 1^2 - 2\tfrac{1}{2} : 1.$$

The general practice among American manufacturers of bi-polar dynamos and motors is to use either cast iron entirely or cast iron yokes and pole pieces and wrought iron cores. In the latter case the sections of the cast iron parts are usually made only about one and a half times that of the wrought iron.

With these proportions between the wrought and cast iron either an excessive amount of magnetizing force must be expended to drive the magnetism through the pole pieces and yokes, or else the wrought iron core must be only saturated to a very low degree. The amount of copper or field current must be, in either case, considerably increased above that required when the cast and wrought iron parts have their correct relative proportions. Magnetic leakage is considerably increased by the use of cast iron, as compared with wrought iron, by reason of the greater surface of cast iron, also the much higher relative degree of saturation at which it is frequently used.

It is evident from the above that the weight of iron and copper for the field magnet and winding in a machine of given capacity are both more than twice as great when cast as when wrought iron is used entirely. When the field magnet is made partly of cast and partly of wrought iron, the increase of iron and copper is not so great and varies with the relative section of the cast and wrought iron parts. The advantage of wrought iron over cast for the field magnets of bi-polar dynamos seem to be more generally appreciated in England than with us, as nearly all the leading makers of such machines there use forged wrought iron entirely for field magnet frames. As the relative magnetic value of wrought and cast iron become more generally appreciated by dynamo builders in this country, the former will, no doubt, be much more generally adopted.

---

[1] Abstract of a Paper read before the National Electric Light Association, St. Louis, Mo., February 28 to March 2, 1893.

The following data of a two horse-power, 110 volt motor, designed by the writer, and having a forged, wrought iron field magnet throughout, may be of interest as illustrating some of the above points:

Type of motar, bi-polar. Type of armature, smooth core Gramme. Weight of motor, 250 pounds. Speed of armature without load, 1,700 revolutions per minute. Turns of wire on the armature, 360. Size of wire on the armature, No. 15 B. & S. gauge, Weight of armature wire, $3\frac{7}{10}$ pounds. Resistance of armature, cold, $\frac{38}{100}$ ohm. Resistance of field coil, cold, 140 ohms. Current in field coil, $\frac{78}{100}$ ampere. Wire in field coil, 26 pounds No. 21 B. & S. gauge.

Particular attention is called to the number of turns on the armature of this machine, namely, 360, which is very small when its weight and the moderate speed at which it runs are taken into consideration. It is very evident that these results could not have been obtained had cast iron been used, either wholly or in part, for the field magnet.

It may be pointed out that the weight of wire and the energy required for field excitation might have been considerably reduced had it been thought best to reduce the length of the air gap, but it was desired that the field exciting force should practically overcome the tendency of the armature to distort the magnetic field in the air gap, which result has been obtained by the above construction, so that no change of lead, with the brushes, is necessary when the load of the motor is varied from nothing to its full capacity.

THE VULCANIZING PROCESS FOR PRESERVING AND STRENGTHENING POLES, CROSS ARMS, TIES, ETC.[1]

BY HARRY C. MYERS, PH. D., F. C. S., ETC.

WHEN we consider that the annual consumption of timber in this country equals twice the amount of material supplied by the annual growth of our forests, it is apparent that the subject of wood preservation, wood strengthening and the utilizing of certain woods now considered as worthless, is a most important and vital one.

Wood as it occurs in nature consists of cellulose impregnated with resin, volatile oils, sugar, gum, tannin, protein bodies and the usual mineral constituents of plants. The percentage of these various constituents, of course, depends not only upon the kind of wood, but upon the season of year, locality, nature of the soil, and part of the tree from which any given sample is taken, hence any results or tests would be only approximate ones.

When wood is heated, as in ordinary wood distillation, the cellulose decomposes and a chemical change takes place between it and the natural constituents of the sap, resulting in a most powerful antiseptic mixture containing acetic acid, methyl alcohol, acetone, methyl acetate, tarry matter containing phenol, creosote, carbolic acid and about 30 other chemicals of lesser practical importance.

The following percentages by weight were distilled from various woods:

Yellow pine	57.8 per cent.
Norway pine	56.8 per cent.
Virginia pine	60.2 per cent. to 72.1 per cent.
Red oak	55.3 per cent.
Spruce	58.7 per cent.
White pine	61.2 per cent.
Poplar	59.0 per cent.
Cypress	59.0 per cent.

It must be borne in mind that these chemicals and antiseptics result from the action of *heat* on the natural sap of the wood, and are *entirely different* from the original sap which allows of the attack of microscopic fungi and decay. Why has it occurred to no one to heat timber at a temperature which would produce the above change, and then to *keep the changed antiseptic mixture there under pressure*, instead of destilling it *out* of the wood? Such is the entirely new and original process known as "wood vulcanizing," viz., the heating of wood and timber under great pressure.

Hundreds of processes for preserving wood have been patented, and all of them may be divided into two classes: I. Those in which wood is impregnated with a preservative material by immersion. II. Those in which a preservative agent is forced into the pores of the wood. Such chemicals as copper sulphate, zinc chloride, mercuric chloride, dead oil, etc., have been applied, but experience and results have failed to prove them all that is to be desired in an economic and effective means of wood preserving. The poisonous nature of such chemicals makes the application and use of them very objectionable.

In the process of "vulcanizing," wood is heated in closed cylinders from eight to twelve hours at a temperature ranging from 300 degrees to 500 degrees Fahrenheit and under a pressure of from 150 to 200 pounds to the square inch. A circulation of superheated and dried compressed air removes the surface moisture and any water that does not take part in the reaction and combine with the woody constituents. Hence, wood or timber, in any condition, may be immediately treated. These cylinders for the treatment are 105 feet long, $6\frac{1}{2}$ feet in diameter and are made of steel. As the treatment penetrates to the heart of the timber, considerable time is required for cooling, which is, of course, done in the cylinder and under pressure. Timber is introduced and treated upon cars which run into the cylinder upon small tracks. The percentage of dark antiseptic matter contained in *vulcanized* woods I find to be as follows:

Vulcanized yellow pine	55.3 per cent.
Vulcanized Norway pine	56.7 per cent.
Vulcanized Virginia pine	58.9 per cent.
Vulcanized red oak	54.0 per cent.
Vulcanized spruce	57.9 per cent.
Vulcanized white pine	55.5 per cent.
Vulcanized poplar	59.0 per cent.
Vulcanized cypress	56.8 per cent.

The samples from which these results were obtained were companion pieces to those from which the previous were obtained; a comparison shows the percentage of moisture removed by the vulcanizing process.

This process apparently makes decay impossible by sealing up the pores of the wood with antiseptic matter which becomes solid and firm on cooling and standing, and which is produced *within* the wood by the action of heat and pressure upon its original sap.

The original sap is colorless or pale yellow, and the changed sap very dark or black, hence a most desirable dark antique color may be imparted to oak and other woods.

The following tests were made at the School of Mines, Columbia College by request of the Western Union Telegraph Company, upon cross arms to be used on telegraph poles.

In each case two cross arms were made from the same piece of timber; one was vulcanized and the other left untreated. Results below give, in pounds, the weight required to break each cross arm:

Vulcanized Norway pine	3,000 pounds.
Natural Norway pine	2,680 pounds.
Vulcanized cypress	2,600 pounds.
Natural cypress	1,860 pounds.
Vulcanized spruce	2,780 pounds.
Natural spruce	2,460 pounds.
Vulcanized poplar	2,840 pounds.
Natural poplar	2,560 pounds.

These startling results show an average *increase* in strength of 18.9 per cent. Similar tests made by Prof. R. H. Thurston and Mr. Alfred Trautwein, of Stevens Institute, verify the above results.

The Hon. B. F. Tracy, Secretary of the United States Navy, with a view of adopting vulcanized wood in naval construction, appointed a committee who visited the vulcanizing works in New York City, made tests of their own on yellow pine, showing an average increase in strength of 18 per cent. and a decrease in deflection of over 13 per cent.; hence, they reported that vulcanizing increases the durability and strength of timber, and recommended such timber for use as backing in one of the monitors.

Untreated cross arms which had been painted and used by the Bell Telephone Company for from two to three years showed, by actual test, an average *decrease* in strength by exposure of 18.78 per cent., as compared to new untreated cross arms. Other pine cross arms which had been in service on Western Union telegraph poles for three years and over showed an average loss in strength by exposure of 38.12 per cent. The process of vulcanizing seasons all timber, thoroughly preventing any further warping, checking or cracking. Such timber is not influenced by atmospheric agencies, bacteria or spores, and requires no paint for protection, as it is saturated with antiseptic preserving material of its own; the albuminous constituents of the natural wood have been coagulated by the high heating and rendered insoluble.

Loblolly pine, as it is used in the South, decays in about three years, and is unfit for any railroad construction where it is exposed to the elements. Other woods are seasoned and rendered beautiful by vulcanizing, which produces very desirable colors for interior decoration.

The life of vulcanized timber is not known; none of the timber or ties used in railway construction during the past 10 years have been known to decay. I personally examined some 12 x 12 pine timber which had been placed in a machine shop in 1882, part being vulcanized and part untreated. The treated timber is perfectly sound and still in use, while the untreated had completely rotted and crumbled away after five years' use. I also find by personal investigation that timber placed on the Manhattan Elevated Roads of New York City, as far back as 1883, shows no signs of decay, and is as sound and sweet as if fresh from the tree, while untreated timber laid at the same time has rotted away and been replaced.

As vulcanizing changes the sap from the liquid to the solid or semi-solid state, does not char or make the wood brittle, saturates and seals up the pores of timber with solid matter instead of liquid soluble matter which nature provides, considerable strength and durability are added by vulcanizing, the wood being rendered more cohesive, harder and denser. The spike holding quality is naturally much increased, and even after 10 years' service, railroad spikes seem to be as firmly imbedded as when just driven.

---

[1] A Paper read before the National Electric Light Association, St. Louis, Feb. 28 to March 2, 1893.

It is also a curious fact that the electrical resistance of most woods is very greatly increased by vulcanizing.

RELATION OF INSURANCE TO ELECTRIC LIGHTING AND POWER [1]

BY WM. BROPHY.

THOSE engaged in the insurance business and those engaged in the manufacture and sale of electric lighting apparatus, as well as those who furnish electric light and power, have one common end in view, viz., to secure at least a fair return on the capital invested in their business and for their own time and labor. Each of these interests needs the help of the other, and there is no good reason why one should antagonize the other. That this has been done in the past I will not deny, but to say that the insurance companies were wholly to blame for their hostility to the introduction of the electric light would be manifestly unfair, to say the least.

Insurance companies have paid dearly in the past for the mistakes of those engaged in the introduction of all modern forms of artificial illumination and many forms of heating, a few of which I will here enumerate. Since the days of the tallow candle and whale oil lamp, we have had gas, camphene, burning fluid (rightly named), kerosene, refined petroleum and its products—naphtha and gasoline—some of which have caused enormous losses by fire to the owners of property and insurance companies, and the loss of thousands of human lives.

After these costly experiments, was it to be wondered at that the insurance interests should view with mistrust this new and mysterious force, electricity, when the attempt was first made to work it in harness to furnish light?

How to deal with this new and to most people's minds dangerous element was a most serious question with the underwriters of this country. To many it seemed best to increase rates all along the line where it was introduced, and thus prevent or discourage its use. Had such action been taken there is no doubt but it would have had the effect of retarding the growth of the electric lighting business very greatly indeed. Fortunately, this last expedient was resorted to in only a small portion of this country.

In that little corner of our great and glorious country known as New England, the insurance organization known as the New England Insurance Exchange was most fortunate in its selection of a chairman for its then new committee on electric lighting. He found time while performing his regular duties as a special agent to post himself up in the mysteries of dynamic electricity, and as his knowledge increased his friendship for this form of illumination and those engaged in producing it increased in like proportion.

To those inspectors who are engaged in an attempt to throw discredit on those engaged in the electric business, by practically saying, "You are not to be trusted," I will say, Beware, the electric industry is not the puny infant it was some ten years ago. Millions are now invested in it, while the phenomenal growth of the electric railway challenges the admiration of all, and it is fast attaining the vast proportions of the electric lighting industry. These joint industries will submit good-naturedly to all reasonable requirements exacted by your employers, but they cannot be expected to submit to continual annoyance or admit that they are unable to conduct their own business much longer by those who seek to do so by might and without a shadow of right. The electric light business can exist without the fostering care of these self-appointed guardians, who seek to magnify their own importance by throwing discredit on this association. Because they are tolerated they must not seek to dictate, as there is a point beyond which forbearance ceases to be a virtue with all classes, and the electric lighting companies do not differ materially from the rest of the human family in this respect.

Having given you a little of the early history of the combined efforts of those who sought to make the electric light safe in its early days, and pictured some of the obstacles that had to be met and overcome, I will try to point out the best methods to pursue to stop the silly twaddle about the dangers of electric lighting by professional agitators, sensational newspapers and timid old ladies of the male persuasion, and deprive the smart (?) insurance man, who insist that there are hidden dangers contained in every portion of the plant, that compels him to charge an increased rate of premium for its production and use of his stock in trade.

In the city of Boston, the Board of Underwriters have for a number of years maintained a system of electric light inspection, paid for by assessments levied on electric lighting companies, also on firms and individuals engaged in electric construction. The city is compelled by State law to maintain a similar system of inspection. In addition to this, one of the electric lighting companies, whose officers are not possessed of an abiding faith in either of the above-named systems of inspections, makes it a point to inspect all wiring before they will connect thereto. Yet with all these safeguards and checks on those engaged in electric ligting and construction, some men "claim to see a connection between the growth of the fire loss and the growth of the use of electricity."

The real fact in the case is that millions of insurance has been placed by the agents and brokers on property that is far more hazardous than the very poorest electric light plant in the business portion of the city in question; ordinary prudence having been thrown to the winds in writing such insurance, the inevitable consequences of such folly ensue, viz., disastrous fires. The agent who sees a possible loss of commissions hastens to give a plausible excuse to his companies, by charging the origin of the fires to electricity and demands an investigation of the fire department for not extinguishing them before they were kindled, concealing the fact that his own methods of placing insurance encourage incendiarism and promote carelessness.

In view of the fact that it is now proposed to add a small charge to the rate of insurance where electric lights "are installed in compliance with board rules and specifications," and a charge of 25 cents where they do not meet with the approval of the insurance inspector, I would advise you to pursue the following course:

Where a company does its own wiring for its customers, proceed with as much care as though the building in which you are installing wires and fixtures was your own, and you had no insurance on it. Where the work is done by others, inspect every foot of wire, every joint, cut-out, switch and insulator, and on no account turn on current until you are satisfied that it is as safe as it is possible to make it. Do not rely on the uncertain movements of the insurance inspector or any other system of inspection that too often fails to inspect. You are the one whose business will suffer from the bad effects of fires caused by defective wires.

We now come to the electric light station. Do not rent one end or the basement of a flour, saw or planing mill and place your machinery in it and expect to get any better than the rates charged on the buildings named above. While they are considered extra hazardous risks, insurance boards in their wisdom (?) will tell you that the introduction of electric light machinery increases the hazard and also the rate. This statement may cause you to smile, but there are those whose early experience have found it no laughing matter. Do not place it in some old abandoned building, for, as in the above case, an increase of rates will follow. Do not set your machinery down on the ground and build a tinder box around it, for besides assuring high rates of insurance it does not speak well for the business sagacity of the owner.

Proceed as though you proposed to do a legitimate business and for all time. Build your station on solid foundation, the walls of brick or stone, not over two stories high—better only one—solid brick or stone foundation for engines, boilers, dynamos and pumps; a solid brick wall extending three feet above roof between boiler and engine-room; the floor of boiler-room of brick, stone or cement; if the building is two stories high, have the boiler-room the same, having clear, open space between floor and roof; floors of engine-room, if dynamos are not placed therein, can be of iron or stone; if dynamos or other apparatus are in the same room, floor should be of three inch plank, tongued and grooved, with hard wood floor of one inch boards, matched and laid at right angles to, or diagonally on, the plank, the whole laid on heavy square timbers or iron I beams; the roof should be of three inch plank, splined and grooved, resting on square, hard wood timbers or trusses of iron or I beams; cover this with slate, tin or gravel, according to pitch; leave the walls bare; do not attempt to improve their looks by covering them with wood and creating concealed spaces; roof and ceiling, ditto; enclose stairways with plank, and provide self-closing doors therefor; cover the doors in brick partition walls with tin; also the frames; do not build a wooden hen-cup or Turkish pagoda on top of roof, and call it a wire tower; build from floor of dynamo room, of brick or tile, a good substantial tower, of ample size for all wires; put them in systematically and not by guess; make switchboard of good, hard, well seasoned wood, skeleton in form, or use the sides of brick or tile tower; if slate switchboard is used, bush all holes through which wires, plugs or other connections carrying high potential currents pass, with glass, porcelain or hard rubber; do the same if sides of brick wire tower are used; use this same material where wires pass through floors or other woodwork; secure a supply of water for protection against fire from town or city mains, if available and pressure is sufficient. In doing this have pipe leading into station of ample size. It costs no more to excavate for a six-inch pipe than it does for a one-inch, and the difference in cost of pipe is not enough to outweigh the value of an abundant water supply in case of fire, for, like the Texan's revolver, then is the time when you want it and want it bad. If water cannot be secured in this way, make your boiler pumps sufficiently large to throw, when connected together, or working singly, from three to five hundred gallons per minute, according to circumstances. Remember that all electric apparatus, including dynamos, is very susceptible to damage by fire or water, and by reducing the amount of combustible material in your plant you reduce the possibilities of a large fire and the necessity for a large amount of water.

---

[1] Abstract of a paper read before the National Electric Light Association, St. Louis, Mo., February 28 to March 2, 1893.

Do not, if possible, build your station adjoining or too close to such risks as oil refineries, planing, saw, and flour mills, grain elevators, etc. If obliged to do so, have no, or as few, openings as possible in the exposed side or end, and provide metal covered shutters for these few. Run all your wires in plain sight, leaving ample space between them. In planning your station, allow for future growth and enlargement, without disturbing the present arrangement of machinery, etc. Store your oil, and, if possible, your other supplies, outside the station, and if you have a repair shop, do not have it in the second story, attic or basement. It is much better outside the building. If you must have it in the building, do not box it up out of sight, but separate it, if you must, by an open partition or fence from the rest of the building. Divest your own mind of the idea that dirt, grease and slush must be the wedded partner of an electric light station, and impress on that of your employés that an absolute divorce must be granted if the marriage ceremony has been performed. "Cleanliness is next to Godliness," but nowhere does this maxim apply with such force as in an electric light station.

Having finished your plant in accordance with the foregoing requirements, you need have no fears of acts of unneighborly conduct or apparent neglect of your property by the ever active insurance agents. Instead of waiting for you to see them out and beseech them to insure it, they will be as attentive to you as the most ardent young suitor ever was to his lady-love. Remember that so-called tariff rates and agreements, that hold insurance associations together for the purpose of maintaining high rates are but ropes of sand, and that keen weapon, active and oftentimes bitter competition, is continually cutting it up in little pieces and letting this craft, that should be rightly named "Trust," drift on the hostile shore of independent action.

REMARKS CONCERNING POWER TRANSMISSION FROM THE ECONOMIC STANDPOINT.[1]

BY L. B. STILLWELL.

AT the Buffalo Convention of the National Electric Light Association, in February, 1892, in the general discussion of the subject of electric transmission of power, a great deal was said about different systems of electric apparatus which might be employed for this purpose and various opinions were expressed concerning volts, amperes, cycles, alternating versus direct current systems, and one-phase, two-phase or three-phase machinery. The subject appeared to be one of great interest to the Convention, and the discussion was more or less instructive. But the writer carried away from that Convention the impression that after all the manager or owner of a central station, or the business man desirous of securing information as to the practicability of profitable investment, must have failed to derive any great amount of information of the kind which he desired to obtain. The first question of such a man is, Does it pay? and it is a question which an engineer who has become so involved in the consideration of technical points as to lose sight of the question of practicability from a business standpoint has great difficulty in answering. But the business man is right. "Does it pay?" strikes direct at the root of the whole matter. The practicability of all systems, and of all projects of this description must be measured in monetary units, and electric transmission of power, as well as every other form of engineering undertaking, must find its ultimate reason for existence in considerations of economy. Any engineering project which cannot live when measured by this standard should never be undertaken.

In discussing the subject briefly from an economic as distinguished from a technical standpoint, I wish to say at the outstart that I am aiming to obtain information rather than to impart it. The question which the practical man asks as to the economy of a project is the most difficult to answer. No answer that is perfectly general, and, at the same time, definite, accurate, and infallible, can be made. The problem, broadly considered, is one of extreme complexity, comprising a large number of factors and these are nearly all variable, whose actual values for any given case depend upon a variety of local conditions, the precise effect of which is not easily determined. Very few men, even among those who are actually operating central stations, are able to say exactly what power costs them, and it is not surprising that the engineer who is called upon to lay out, let us say, an elaborate plan for the utilization of water power finds it difficult to give explicit answers to questions relating to the cost of operating such a plant, probable revenue to be derived from the sale of power, and, in general, economic feasibility. It is safe to say that no perfectly general solution of the economics of central station operation can be worked out. Time, and the sure working of evolutionary law will some day clear away much that in the early days of a new business is inevitably more or less uncertain and speculative, but it is not to be expected that we shall even then be able to reduce these matters to fixed formulas. Of ten thousand plants the fittest will survive and pay dividends, and central station engineering will then consist of close study and careful analysis of the conditions and methods which have led to the survival of these fittest installations. In other words, central station engineering will then be largely imitation.

At the present time we find in actual operation a large number of central stations utilizing the energy of coal by means of steam plants, and distributing power and light through the medium of various types of electrical apparatus. The number of central station plants operated by water power is, on the other hand, extremely limited. There is to-day perhaps no question of greater interest to owners and operators of central stations than that of the relative economy of transmission plants utilizing water-power, and it will, therefore, be interesting to narrow the general problem of economics of central station operation in such a manner as to indicate how experience in the operation of the former class of plants may be made useful in predicting what will happen if water-power be substituted for steam. The best way to arrive at results of some tangible value is obviously to compare an hydraulic and electric transmission plant with a central station using steam engines to drive dyamos.

In the former we have the steam plant, consisting of boilers, engines, pumps, heaters, etc.; the electric generating plant comprising dynamos, exciters and all electrical apparatus located in the central station; and the distributing plant comprising motors, lamps, transformers, and the conductors connecting these with the central station. In the latter case it is usually convenient to locate a sub-station at a point adjacent to the market; for example, on the spot where the central station would be located were we to obtain power from coal. In such a plant we have the hydraulic apparatus, comprising dam, flumes, draft tubes, turbines, regulators, etc.; the electric generating plant, consisting of generators, exciters, and all electrical apparatus located in the generating station; the transmission circuits between generating station and sub-station; electrical apparatus in the sub-station, which usually consists of transformers employed to reduce potential, together with switching and regulating apparatus; the motors, lamps and other translating devices, and the local distributing circuits connecting these with the sub-station. We may assume that the two installations from the point where the local distributing circuits leave the generating station on the one hand, and the sub-station on the other to the premises of the consumer, are precisely similar. There is no reason why they may not be so, and since the whole installation, no matter which of the two alternative plans is adopted, must be designed to supply such service as the customer wants and will pay for, the assumption is perfectly fair. It follows that if the two contrasted plants are capable of delivering the same amount of power to the local distributing circuits they are alike as regards revenue. We may, therefore, at this point make our comparison still more direct by further narrowing the problem, disregarding the revenue side of the question, and comparing simply annual charges. It is obvious, also that it is unnecessary to compare annual charges upon that part of each of the contrasted plants which lies between the customer and the central station in the case of the steam plant, and between the customer and the sub-station in the case of the hydraulic and electric transmission plant. In other words, that phase of the general problem which I have selected as perhaps the most interesting may be stated as follows:

"What are the total annual charges against an hydraulic and electric installation utilizing cheap power at "A" and transmitting it to "B" as compared with the annual charges against a steam and electric plant located at "B," and capable of supplying the same amount of energy in equivalent form to the local distributing circuits?"

We may conveniently construct an algebraic skeleton or framework of the annual charges against each of these typical installations. When we come to translate algebra into arithmetic by substituting numerical figures for the algebraic symbols, opinions will differ widely as to the actual values of the different factors, but I think that the skeleton will be useful, as by discussing, and, if possible, fixing one factor at a time, we shall be better able to arrive at some approximation to a definite and tangible result. The method outlined in the skeleton-framework is, of course, the method which a competent engineer who may be called upon to make estimates of the operating expenses of such plants will adopt; that is to say, he will naturally consider each item of expense separately, and make his calculations step by step. But the proper factors largely depend upon results of experience in the operation of plants sufficiently similar to make inference from one case to the other fairly safe, and accurate data relating to such experience is at the present time very difficult to obtain. My object, therefore, in this paper is to invite your attention to each of the various items of expense in such installations, to obtain information from your experience and to suggest that it is in the power of the members of the National Electric Light Association to collect such a mass of data concerning the economics of central station operation, and the distribution of energy for light and power purposes, as will be of the utmost value in judging of the practicability of the thousands of projects of this description which will be under consideration within the next 10 years. It is also in the power of this Association to compare, analyze and arrange this information in such a way as to make its application to a new project direct and reasonably conclusive. If there be any means by which failure in ventures of the kind, in which you are and will be interested, may be avoided we should certainly put ourselves in possessison of these means as early as possible, and I would, therefore, respectfully urge the advisability of concerted action, looking to the collection and proper analysis of information concerning each of the various items of expense, and the various sources of revenue of your central stations. The problem is somewhat complex, and unless we have some definite and progressive method of analysis it is practically impossible for an association which may be considering the subject, or even for a select committee of engineers who may be called upon to advise with reference to a specific case, to arrive at an agreement in which all will concur. I believe, therefore, that we may make good use of the skeleton statement of annual charges.

---

[1] A Paper read before the National Electric Light Association, St. Louis, Mo., Feb. 28 March 2, 1893.

In calculating the annual charges against the steam and electric plant we must consider the following :—

F_b = First cost of real estate and buildings.
F_b = Percentage covering interest upon and maintenance of real estate and and buildings.
C_b = Constant expenses, taxes, insurance, etc., on real estate and buildings.
F_s = First cost of complete steam plant, including engines, boilers, steam pipes, pumps, heaters, etc., installed.
P_s = Percentage covering interest upon and maintenance of steam plant.
A = Cost of fuel to produce one pound of steam.
S = Pounds of steam used per indicated h. p. per hour.
N = Number of indicated horse-power hours used per year.
W_s = Cost of water (if any) per annum.
O_s = Cost of oil and waste per annum for steam plant.
F_e = Cost of electric generating plant, including exciters, regulators and complete station equipment.
P_e = Percentage covering interest upon and maintenance of electric generating plant.
O_e = Cost of oil and waste per annum for electric plant.
C_{se} = Constant expenses including superintendence, wages, taxes, insurance, etc., steam and electric plant.

Then = $P_b F_b + P_s F_s + A S N + W_s + P_e F_e + O_s + C_{se} + O_e$ = annual charges.

For the hydraulic and electric plant we have the following :

F_b = First cost of real estate and buildings.
P_b = Percentage covering interest upon and maintenance of real estate and buildings.
C_b = Constant expenses, taxes, insurance, etc., on real estate and buildings.
F_h = First cost of hydraulic plant including turbines, dams, flumes, etc.
P_h = Percentage covering interest upon and maintenance of hydraulic plant.
O_h = Cost of oil and waste per annum for hydraulic plant.
C_h = Constant expenses including superintendence, wages, taxes, and insurance on hydraulic plant.
A = Cost of water per horse-power hour (where water rate is paid).
N = Number of horse-power hours at turbine used per year.
F_e = First cost of electric apparatus between turbine and local distributing circuits exclusive of line.
P_e = Percentage covering interest upon, and maintenance of, electric plant exclusive of line.
O_e = Cost of oil and waste per electric horse-power from generators for electric plant.
C_e = Constant expenses, including superintendence, wages, taxes, insurance, etc., on electric plant.
F_l = First cost of pole line, insulators and conductors.
P_l = Percentage covering interest upon and maintenance of pole line, insulators and conductors.
C_l = Constant line expenses (supervision and repairs).

Then $P_b F_b + C_b + P_h F_h + O_h + C_h + A N + P_e F_e + O_e + C_e + P_l F_l + C_l$ = annual charges.

And now, what have we accomplished? We certainly have not arrived at a definite solution of the problem of comparative annual charges, and the more carefully one looks at the statements, the more evident does it become that there are many factors the value of which can only be fixed by actual experience. It appears, however, that were we in possession of accurate and detailed data as to the cost, operating expenses and income of a steam and electric plant, we might form a pretty accurate idea of the practicability of an alternative project involving electric transmission of power. We should also need some information as to the cost of installing and operating hydraulic plants under various conditions, but this can be obtained with sufficient accuracy and with no great difficulty. The evolution of apparatus adapted to the efficient and reliable transmission of energy, and hence to the utilization of vast amounts of power in the form of falling water now wasted has reached such a stage as makes this question a most vital one, and the importance of information relating to the cost of steam and electric plants now in operation is manifest.

This paper is offered simply in the way of suggestion and for the purpose of inviting criticism and comparison of opinions. The skeleton statements of annual charges have been hastily prepared and may doubtless be revised and amended with good results. It is intended simply for classifying purposes, to facilitate the accumulation of much needed data and to avoid confusion of ideas in discussion of the problem which I have attempted to analyze. I sincerely trust that the suggestion will be taken up by this association and effective steps taken to increase our fund of observed facts based upon experience, so rendering a most valuable service to engineering science and promoting the general welfare of all who are interested in the practical use of electricity.

LONG DISTANCE TRANSMISSION OF POWER. [1]

BY CHARLES S. BRADLEY.

FOR the electrical transmission of power we have two general systems—the alternating and direct. The multiphase alternating was advertised extensively by the Lauffen-Frankfort plant in 1891. This pioneer plant was built by much sacrifice of time and money, and we owe gratitude and honor to these men whose indefatigable efforts accomplished the beginning of an art which is destined to revolutionize the social status of mankind. This plant proved conclusively that very high voltages could be successfully used and the insulation maintained. This is the whole thing in a nut-shell; the choice of this or that particular way of generating and using the energy is of secondary importance, and will vary with each situation; surprising as it may seem, the maintenance of the insulation was the least trouble in the operation of this plant. One of the greatest is the interference with the telegraph which belongs to the German Government, and when the German Government says "stop," it means stop (in Germany). The difficulty next in importance is the static induction, each wire, being so long and exposing so much surface, becomes a reservoir to hold electricity, and the generator must fill this reservoir on each impulse before it can deliver energy at the distant end. When the generator reverses the direction of current, as it does some 100 times per second in the alternating, this reservoir must be discharged and filled with electricity of opposite sign: that is, if the first impulse to a given wire is positive and fills its capacity with the positive electricity, the reverse impulse must discharge the positive and then fill the reservoir with negative electricity. This operation consumes but little power; it is an ebb and flow, as it were. The trouble, however, is that this idle current swinging back and forth occupies the carrying capacity of the generating apparatus; so much so, that I saw the fuses blown at Lauffen with no load of consequence at the Frankfort end. In damp weather the insulators become wet on the external surfaces, and this largely increases the capacity, which is more serious than the increased leakage. These difficulties vary with the length of the line and the amount of power transmitted, the surfaces being proportional to the length of line. The carrying capacity is proportional to the square of the diameter of the wire, while the static capacity is proportional to the surface, which is equivalent to being proportional to the diameter, so that the larger the amount of current transmitted the less proportional influence the static capacity has. These things must be determined by the engineer in each case. The Lauffen-Frankfort was an extreme case. First, the line was much longer than we shall expect for some time to come in practical work; second, the plant was intended for 300 h. p. and a rate of 40 periods per second. Owing to the static effects at 40, the rate had to be lowered to about 23 per second; this obliged them to run the dynamo at very much reduced speed, so that it was capable of only about 100 h. p., and this reduction increased the proportion effect of the static charge. In long distance transmission the lines should be carried on poles whenever it is possible, for the farther apart the conductors are, the less will be the inductive capacity; if placed under ground they will of necessity be near together. The placing in separate conduits to gain distance will not help, for the nearness of the earth is the equivalent of the nearness of the conductor of opposite sign. These things are only warnings, however, and slip out of sight with proper precaution. The multiphase alternating is the most pliable, adjustable system that has ever been conceived. Where the power is to be delivered in compact form the direct current offers some important advantages. We can get very high voltages by a battery of machines placed in series for the generator and motor stations. The placing of machines in series for power transmission was proposed by Mr. Edison in 1880 and Prof. Thomson in 1883. Each contributed some essential improvement, but it is evident that the enormously high voltages now contemplated were not then thought of. For the generator station I prefer compound wound machines; first, that the system may be self-regulating; second, that the series coil when a machine is thrown into action shall magnetize the field in the right direction; this also requires that the switch shall close the series coil first. The shunt coil would tend to reverse until the machine has attained E. M. F. enough to overcome the resistance of its own armature. In order that each machine shall be as far as possible independent of its neighbors, I prefer that it shall be short shunt, or in other words, the shunt coil be charged direct from the brushes of each machine. I would use the 500-volt machines, and of such ampere capacity as the size of the plant demanded, and belt them all from one shaft. The 500-volts have been found safe to life and the commutator works well. Now, we must protect the insulation of the windings; the end machines where the terminal voltage, say, reaches 20,000 volts may, in case of grounds, be subjected to the piercing strain of the entire electrical pressure. It is impracticable to insulate the windings of each machine to stand any such potential; therefore, we connect the windings of the machine at some point with the frame so that it may never be subjected to a strain greater than its own voltage; next each machine foundation is thoroughly insulated from earth, and, in case this insulation fails for any reason, the fuses of the line will be blown, thus protecting the whole structure. It is easy, however, to make this foundation insulation so perfect that no derangement will take place. For this, I have struck upon a cheap plan, which was not apparent at first. Having now provided for the insulation, we must next consider the safe handling of the machines. A moment's consideration of the electrical potential of each successive machine in the series will make it evident that the whole of each machine will attain the potential of its individual position; or, beginning at one end, each successive machine will be 500-volts above the preceding one. Now, like standing on a stool with glass legs, a man may be placed upon any one of these machines, and if he cannot touch any conductor to earth he is perfectly safe. We can use a wooden platform around and attached to the base of the machine, so that the man must cross it before he lays his hand on the metal part. Here, again, I want to point out how essential it is that the windings be in metallic connection with the frame for the safety of the man. It secures that no part of a machine shall exceed its own voltage, and, in case of a leakage in the foundation insulation, immediate detection. If this metallic connection were not provided and a leakage occurred in the foundation, you will readily see that it might be undetected, and a man touching the brushes and the frame would take a current through him of uncertain high voltage. At the motor station we use simple 500-volt shunt machines with the same precautions as at the generator station. Our power having been transmitted can now be converted into whatever may be demanded. If it is an electric system of distribution, we shall have the advantage of its being impossible for the high tension current to get into the system of distribution. If it is a large plant, the motor station may be subdivided into two or three parts, preferably in multiple arc, with the same potential on each. On very long lines I think the transmission must be done by direct current. To prophesy, although a temptation, is futile, for the lines of progress are not as one man would think, but as the multitude of surrounding circumstances determine.

---

[1] Abstract of a Paper read before the National Electric Light Association, St. Louis, Mo., February 28 and March 1, 2, 1893.

THE INCANDESCENT LAMP FROM A COMMERCIAL STANDPOINT.[1]

BY CALVERT TOWNLEY.

In discussing the relation between the life and efficiency of different lamps, we may consider simply the characteristics of their burners. For convenience in discussion, we may divide the commercial lamp burners into three classes, viz:

1st. The untreated or natural burners used in the Edison lamps.

2d. The treated or flashed burners used in the Sawyer-Man, Thomson-Houston, Beacon, and a number of other lamps.

3d. What we may call the super-treated burners used in the new Westinghouse stopper lamps.

In all published tests of the life of burners there is shown to be a definite relation existing between the life of a carbon and the temperature at which it is burned, this relation remaining fixed for carbons of the same kind and varying only for carbons of different kinds. If we formulate this relation, it will assist us to determine what temperature of any kind of carbon may be expected to yield the best commercial results; that is to say, how much money it is desirable to spend on the maintenance of the carbon, and how much on the energy to heat it. The temperature of a burner is difficult of measurement. It will, therefore, be simpler, and quite as satisfactory, if we consider the relation between life and energy consumed, expressing the latter in watts.

By a series of experiments, extending over several years and covering tests of many thousand lamps, Mr. Frank Stuart Smith has found the relation between the life and efficiency of the Sawyer-Man carbons, and through his courtesy I am permitted to give you the results. The relation is expressed by a curve, where the axis of Y represents hours life, and the axis of X, watts per each candle of light produced.

The exact mathematical expression corresponding to this curve is somewhat complicated, but, as we are considering the question from a purely commercial standpoint, we may consider the curve between commercial limits, in which case we can express the relation within one-half of one per cent. by the formula,

$$L_{,} = 3.742\ E_{,}^{5.78} \qquad (1)$$

where L represents hours life and $E_{,}$ watts per candle.

During the past year a great many tests have been made by Mr. Smith with the super-treated carbons of the Westinghouse stopper lamps, and the relation between life and efficiency thereby found to exist is given by the equation,

$$L_{,,} = 5.44\ E_{,,}^{5.684} \qquad (2)$$

We note that this curve corresponds very closely in its general form to the curve of the treated burners, except that for a given efficiency the life of the super-treated burner is always longer. This is as it should be, inasmuch as the super-heated burner is, in fact, a treated burner which has been subjected to an additional process to render it more stable.

In 1888, Mr. John W. Howell presented a paper before this Association, in which he exhibited a curve stated to have been constructed from the results of a large number of tests made with the Edison or untreated burners. This curve is very similar to the curve of the treated and super-treated burners, and, considered between the same commercial limits, we can express it with equal accuracy by the formula.

$$L_{,,,} = 1.052\ E_{,,,}^{6.453} \qquad (3)$$

$L_{,,}$ and $E_{,,}$ having the same significance as before. For a given efficiency, we find the corresponding life of any class of carbon by tracing a perpendicular line until it intersects the proper curve, the corresponding life being found directly opposite the point of intersection horizontally. Thus, for an efficiency of 2.5 watts, we find the life of the untreated burner to be 400 hours, of the treated burner, 713 hours, and of the super-treated burner, 962 hours.

It is important to remember that these curves represent the results of laboratory tests, in which the E. M. F. is kept more nearly constant than is ordinarily possible under the conditions of central station lighting. Therefore, in order to obtain an expression which will represent commercial conditions, we must introduce the element of a variable E. M. F. Mr. Frank Stuart Smith has shown the relation between total energy consumed and the light emitted. This relation is represented by the equation.

$$I = \frac{W^2}{\sqrt{R^2 - W^2}} \qquad (4)$$

where I equals the total illuminating power expressed in candles and W equals watts, R being a constant, which depends for its value on the size and efficiency of the lamp; R is, in fact, the radius of the circle to which our tangent is referred. While the position of this curve varies with different lamps, the relation between the watts consumed and the light emitted remains unchanged through all tests.

By a comparison of laboratory and central station records a fair average assumption seems to be that, with proper attention to regulation, the commercial variation is equivalent to a constant excess voltage of 3 per cent. I have taken this a basis, and constructed commercial curves for the treated, the super-treated and untreated filaments. It is important to note the great effect that a comparatively small rise in E. M. F. has on the life of a lamp. Any neglect to maintain the best possible regulation, therefore, will result in an increased bill for lamp renewals entirely out of proportion to the variation in voltage itself.

We will not be far wrong, if we assume that the central station company has a market for all the lamp hours it can furnish during a certain portion of the day's run. With this assumption, let us formulate an expression for the profit in incandescent lighting; then we may determine what conditions will give this profit a maximum value. In the consideration of this matter I have taken as the unit of value one 16 candle lamp hour, assuming that what the public want is light, and that, other things being equal, they do not care whether much or little energy be expended to produce it.

With our unit of value illuminating power, therefore, our profit will obviously be the difference between the cost and selling price of a lamp hour multiplied by the number of lamp hours sold. We may, therefore, write the expression—

$$P = (v - c)\,\frac{S}{W}$$

where P equals profit, v selling price, c cost of lamp hour, S output of station in watt hours for the time for which our profit is estimated, and W watts required per lamp. Again, the cost of producing one lamp hour is clearly the proportionate cost of the lamp itself plus the cost of the energy consumed by it. We may, therefore, write—

$$c = \frac{l}{L} + \frac{l}{1000}W$$

where l equals cost of a lamp in cents, L its life in hours, and g cost of producing one kilowatt hour of energy. Substituting in this expression, from the formula of our commercial curves, the value of lamp life in terms of efficiency (bearing in mind that for a 16 candle power lamp $E = \frac{W}{16}$), and putting our expression for the value of c in place of c in the formula representing our profit, we have the equation—

---

[1] Abstract of a Paper read before the National Electric Light Association, at St. Louis, Mo., February 28 to March 2, 1893.

$$P=\frac{VS}{W}-\frac{Sl\,(l+p)^{2b}}{Wa\left[\frac{W^2+256-256\,(l+p)^4}{256}\right]^{\frac{b}{2}}}-\frac{Sg}{1000}$$

where *a* and *b* stand, respectively, for the coefficients and exponents of the second terms of formulæ (1), (2) and (3).

I have taken the original cost of the lamps at, respectively, 35, 50 and 20 cents, the selling price of a lamp hour at, respectively, .5, .75 and 1 cent, and the cost of producing current at, respectively, 2, 3, 5 and 8 cents per kilowatt hour. By the courtesy of a considerable number of central station managers, who have furnished data concerning their respective plants, the average cost of this energy appears to vary between 3 and 7 cents. The only cases where 7 cents is exceeded are those in which fuel is a very expensive commodity and the station output is small. Where 3 cents is too high a very cheap fuel is used and a very large station operated. In assuming these values, I believe that we have covered as nearly as possible the conditions which actually exist, but it is quite easy to adapt our expression to any set of local conditions.

With the price of a lamp hour at one cent and the cost of generating current six cents per kilowatt hour, the best result we may expect from the treated filament lamp at 50 cents each is, with a 38 watt lamp, *i. e.*, 2.37 watts per candle, when our profit should be 16.6 cents per kilowatt hour. With the super-treated lamp at 20 cents, other conditions remaining the same, the best results are obtained with a 30 watt lamp and our profit should be 22 cents per kilowatt hour.

Two facts are especially prominent, namely: first, that although we have assumed strictly commercial conditions, the profits obtained are in excess of those actually made in practice, and, second, that the most economical lamp efficiencies are considerably higher than those of any commercial lamps now in use. It is interesting and very remarkable to note that in every case the profits fall off very rapidly for lamps of either too low or too high efficiency, the variation being more marked where current is dear and running expenses high. By putting these facts together, it is apparently clear that the long lived inefficient lamp is a very expensive article, and that too much weight has been given to the cost of lamp renewals, which shows prominently on the expense side of our ledger, while we have not paid enough attention to the great waste of energy due to low lamp efficiency. We note also that the most economical conditions call for, in the case of the untreated filaments, a life of between 250 and 525 hours; in the case of the treated filaments, a life of between 286 and 620 hours, and in the case of the super-treated filaments, a life of between 138 and 260 hours; the shorter life being in each case where both the cost and selling price of the lamp hour is high.

With a charge of three-quarters of a cent per lamp hour and five cents for the expense of generating one kilowatt hour, the use of a 50 watt lamp loses the operating company 1.05 cents for every kilowatt hour sold when using the 35 cent lamp with the untreated burner; 1.4 cents when using the 50 cent lamp with the treated burner, and 5.2 cents when using the 20 cent lamp with the super-treated burner, as compared with the profits which might be made if these various lamps were used at their respective best efficiencies. It is gratifying to find that the possibility of increased profits carries with it the implied possibility of reduced prices to the public and, therefore, a great demand for light, and greater success to the companies furnishing same, in competition with other illuminants.

I have said nothing in this paper in regard to fall in candle power, for the reason that, in both the treated and super-treated filaments, this fall is roughly proportional to the time the lamp has been burning, as compared to its total life; that is to say, if a filament has a life of 1,000 hours at a given efficiency, and during that time its fall in candle power is *A* per cent., if this filament is burned at an efficiency which will make its life 500 hours, its fall in candle power will still be approximately *A* per cent., so that our commercial results are not appreciably affected. For the untreated filament the fall in candle power is proportionately larger than in the other two filaments. Therefore, if we are making a comparison of total illuminating power per energy consumed, we must put the untreated filament on a somewhat lower scale than shown in the comparisons I have drawn.

POWER TRANSMISSION FOR CENTRAL STATIONS.[1]

By Dr. Louis Bell.

So far as distribution is concerned, we may divide electrical power transmission into three classes: First, the transmission of single units; second, the transmission of power to a centre of supply from which point it is to be distributed in various ways; third, supplying the power for lights and motors throughout the length of the transmission line. Each of these classes of work imposes conditions on the possible methods of transmission, and requires special consideration. In new plants hampered in no wise by existing stations, any one of these three cases may exist, perhaps the last two more frequently than the first. Where a single motor is to be employed, the problem is exceedingly straightforward. Where a new centre of distribution is to be organized, some complications are encountered, but not serious ones. Where power is to be scattered along the line, however, conditions arise which are not altogether easy of fulfillment and require a good deal of special care and skillful engineering.

To the working central station man, occupied with the details of a growing business, power transmission from a distant water fall, possesses a direct pecuniary interest. Sometimes a considerable saving may be effected by using part of the apparatus already on hand, for example, moving his arc machines and alternating lighting machines to the water power, if it is not too far away and transmitting power only for his power circuits or direct current lighting circuits. In a general investigation of the methods which may be employed, the case stands somewhat as follows, so far as the central station man is concerned:

First, if the distance over which he is to transmit power is moderate, he may use the ordinary direct current generator and motor, displace his engine with the motor and go ahead. But unfortunately, direct current machines of any considerable capacity are practically limited in voltage by the existence of a commutator, an article on which central station men in general waste no love. Dynamos and motors of large size cannot, individually, in the present state of the art be satisfactorily built for more than about 1,200 volts. Machines for greater voltage have very generally broken down in the experimental stage. For very small power units, arc machines might be employed, but for the purpose of the central station man, it is better to move his arc machines directly to the distant point. For voltages much in excess of that mentioned, we are then driven to the use of either direct current machines in series or alternating machines.

Where generators and motors are to be used as a single unit, direct current machines in series may be and are employed quite successfully, but as the voltage desirable on the line rises, the system contains a greater number of units and becomes more complicated and difficult to apply to central station practice. For instance, it is highly desirable for the successful operation of motors in series that they should be, practically, coupled to the same shaft, and should run under similar and uniform conditions, so while there are cases in which the method of coupling in series may be both convenient and cheap, it is in my opinion better general practice to employ alternating currents, after passing the ordinary limitations of direct currents.

Multi-phase currents, and by this I mean currents having more than one phase, are subject to the same general laws as any other alternating currents. Their most valuable peculiarity lies in the fact that for alternating currents of more than one phase, excellent motors can be built which will run at a steady speed, start under heavy load, and in general possess very much the same qualities as a well organized shunt motor of the ordinary kind. Incidentally, certain of the multi-phase systems, more especially the three-phase, enjoy the advantage of effecting something of a saving in copper, under favorable circumstances up to 25 per cent. from what would be required by a plain alternating current of the same nominal voltage. This saving is merely from the fact that in the three-phase line, the currents do not have their highest value at the same time, so that at any particular instant, two of the wires may serve as a sort of multiple return for the third. This advantage would be immediately thrown away, if for the three currents of different phase, three separate pairs of wires were employed, as it is thrown away where for two currents of different phase, two independent circuits are used.

The fundamental difference between single and multi-phase systems then, is mainly the adaptability of the latter for driving motors, and multi-phase are better than single phase motors principally in their ability to start under load, and somewhat larger output for the same weight.

Wherever, then, single motors are to be driven for operating, we will say, an electric light station, it is largely a matter of convenience whether we employ single or multi-phase motors. If the former can be conveniently started, they are fully competent to take care of the work, except in one special case which I will mention presently.

A single case in which multi-phase transmission becomes of great importance when the object is to work an existing central station, is in that case where railway circuits are to be supplied. A railway machine is subject to so great and violent variations of load, that if it were driven by an ordinary synchronous alternating motor, the latter would run great risk of being pulled out of phase by a sudden short circuit, when it would stop and stay stopped until deliberately started up again. The multi-phase motor can also be pulled out of phase, but not quite so easily, and it can be more readily started. We can, however, where railway currents are necessary, do much better than to drive the dynamos directly by motors of any kind. We can for this use start with the multi-phase current, and through the medium of a single machine, scarcely more complicated than an ordinary railway dynamo, transmute this multi-phase current into a direct 500-volt current of the ordinary sort. This very valuable result has been brought about through the ingenuity of my friend, Mr. C. S. Bradley, who invented the device a half dozen years ago. It has lain dormant, principally because there has been no special call for power transmission of any kind until recently, but to its thorough practicability, I can personally testify as a 100 kilowatt tri-phase direct current transformer which I recently tested, operated in the manner described, showed an efficiency of over 95 per cent at full load, stood sudden variations from no output up to 100 kilowatts and back again without even a wink at the brushes, and bore up under heavy overload without difficulty. Whenever, it is desirable to operate railway circuits by power derived from a distant source, these machines fulfill all practical requirements, and I believe are destined to come into very extensive use, and play an important part in the development of very long electric railroads.

---

[1] Abstract of a Paper read before the National Electric Light Association, St. Louis, Mo., Feb. 28 to March 2, 1893.

Now, take up the case where a centre of distribution is to be fed, consisting, it may be, in part of an existing station and in part either of extensions and new circuits from this plant, or subsidiary centres of distribution having other districts of the same town. Here the problem becomes more complicated and it is almost impossible to lay down any general procedure. Each case is best handled by itself. We can, however, enunciate certain principles which will aid in the discussion of any definite case.

First, we can feed all existing railway circuits and extensions thereof very effectively and economically by use of the tri-phase direct current transformer just described.

Second, we can handle all direct current incandescent systems, whether two or three wire, by means of the same type of apparatus, the tri-phase direct current transformer.

Third, we can successfully operate any existing alternating incandescent circuits or any extensions thereof by feeding alternating current from the distant point directly into them through banks of transformers.

Fourth, if any new centres of distribution are to be made with circuits independent of those already in existence, we can operate these circuits very effectively for both lighting and motor service if both be necessary by employing multi-phase apparatus, and right here let me say that there is one widely-spread error which I desire most emphatically to contradict.

It has been asserted that incandescent lighting cannot be successfully done on multi-phase systems, especially tri-phase, since this system happens to have been most talked about. This statement is absolutely false, to my own personal experimental knowledge. Lamps can be successfully operated on systems of two, three or more phases as on an ordinary single phase circuit, provided equal pains be taken with the distribution of copper in the lines and the regulation of the voltage at the dynamos. If these conditions are observed, a two phase circuit with separate wires acts substantially as if it were fed from ordinary alternating dynamos. A tri-phase circuit gives a similar result, and if more phases were concerned, the same would be true. If the condition of constant voltage at the centre of distribution be fulfilled as it can be and must be for successful operation on any system whatever, two and three-phase incandescent lighting systems can and do work admirably. Furthermore, if we combine circuits, for example, if we use but three wires instead of six for three-phase systems, there is no exact equality of balance required between the lamps placed in different connections across these circuits. On the three-phase system, we would place lamps between each possible pair of the three wires, this arrangement gaining, as I before mentioned, in copper wire enough to compensate for the slight inconvenience in connecting three sets of lamps instead of one or two.

In taking up the condition I have just mentioned that of a new centre of distribution, I may briefly refer to the properties of multi-phase motors, which have been the subject of all sorts of curious misstatements, A multi-phase motor, I do not care whether it has two or more phases, should if properly built have very nearly the properties of a good shunt motor, and not far from the same efficiency. Incidentally, it has the advantage of having no commutator, and no necessity for any moving contacts. It starts under two, three or more times the running torque, just as a shunt motor does, and by virtue, if the torque is extreme, of a heavy starting current just as a shunt motor would. It comes rapidly up to a nearly fixed speed, and remains nearly at that speed under variations of load. If overloaded it stops, like any other motor, In addition, it has one great merit that shunt motors do not have, that of running at nearly constant speed independent both of load and moderate variations in voltage. It is on the whole less thin-skinned than a shunt motor. I have experimented with a considerable number of multi-phase motors of the induction type, to which I here especially refer, and although I have seen some terribly severe tests in the way of overload, I never yet saw any symptons of a burn-out. The efficiency of these machines should be and is at least within a per cent. or two of ordinary shunt motors. There are two important points in which multi-phase motors have been misrepresented, which I should like to mention. First, it has been stated of them that they take an enormous current when running light, and second, that they introduce a very large and most objectionable lag in the circuit, so that the apparent current on the line is much greater then the energy current. Such facts have doubtless been observed. Broadly speaking, they have been due to faulty design. A multi-phase motor will always take a somewhat larger current when running idle than the corresponding direct current motor, but it takes very little more energy running light as the phenomenon of lag then becomes noticeable, so that of the apparent current, only a portion represents energy. It is a perfectly simple matter to cut down the current required by a multiphase motor running idle to twenty or twenty-five per cent. of the full load current, still retaining a motor excellent in its other properties. As motors where power is sold by meter are usually cut-off when not needed, the whole question of this idle current sinks into insignificance. The same is true of the alleged lagging current, If a multi-phase motor (I speak with certainty at least regarding the three-phase) of 10 or 15 h. p. should show at full load more then 10 or 12 per cent. of lagging current, I should consider it to be badly designed.

Whatever the methods which may be employed, several serious questions must be confronted when one attempts to transmit power for supplying central station or any other apparatus. One of these which presents itself immediately, is whether or not in an alternating transmission it is advisable to use step-up and step-down transformers. The principal determining factor in this is cost. The higher voltage we can supply direct from the machine without increasing its cost considerably, the cheaper we can make the installations. Assuming 2,000 or 3,000 volts as the available potential obtained from the machine direct and then estimating the cost of a given installation, first using these machines, and second, using low voltage machines with step-up transformers, we find that at prices ordinarily charged for apparatus and copper, the two methods become of equal cost, at a distance of somewhere about seven or eight miles. Above these distances, the step-up transformers cheapen the plant, below it, they increase the expense. We can draw the line at no specified given distance for the general case but can very easily for any specific case. The amount of drop advisable in these long distance lines will depend, of course, principally upon the relative prices for copper and the apparatus necessary.

But for the central station man who desires to decrease his operating expenses by the employment of electrical transmission, the court of last resort is the balance sheet, and the fundamental question is, "Agreed that it is practicable, will it pay?" I can give no general answer to this question, for each problem necessarily must be considered by itself. I have, however, looked into the profit and loss probabilities of a large number of plants of all descriptions, and in a general way one can say that power transmission to a central station will, unless the cost of developing the water-power be very great, almost universally pay at distances of 10 to 12 miles or less. It will frequently pay up to 20 or 25 miles. Now and then, under extraordinary conditions (very expensive coal and very cheap water-power) up to 40 or possibly even 50 miles. In using alternating currents at these long distances, one naturally fears the effects of inductance in the lines and of static capacity. In very long lines, operated at high frequency, these difficulties may rise to formidable magnitudes. Knowing the dimensions of the line, the frequency and the currents, it is, however, possible to calculate the effects of these disturbing elements with great accuracy. From these calculations I feel safe in saying that within the distance mentioned, inductance and static capacity constitute no serious obstacle to success, if the frequency employed be moderate.

Throughout this discussion I have taken the position that no one method of procedure is applicable to all cases. Personally, I am decidedly eclectic in my taste, believing that it is better to put in for each individual case such apparatus, as on the whole proves to be cheapest and best rather than to advocate, on any fine drawn theories, methods which might be applied to the perfectly general case of transmission of power. It is the concrete rather than the abstract that we have to consider when proposing apparatus on which the success of large commercial affairs depends, and although some methods are better than others, it is well to remember that while the electrical pharmacopæa may have its calomel and paregoric, it contains no elixir of life.

TRANSFER OF A NEWARK ELECTRIC LINE.

President Barr of the New Jersey Traction Company, John D. Crimmins, Bernard Shanley, and others interested in the big railroad deal in New Jersey, had a conference in Newark recently and signed the agreement necessary for the transfer of the Newark road. It is said that the new managers assume all existing obligations and respect all existing contracts, and are to pay to stockholders a fixed dividend of 5 per cent. per annum, with a pro rata share of the profits on a capital basis. There are 1,800 shares held in Newark. It was stated openly that the Pennsylvania Railroad was interested in the deal.

Vol. XV. NEW YORK, MARCH 8, 1893. No. 253.

THE ST. LOUIS CONVENTION AND ITS OUTLOOK.

THE St. Louis Convention has come and gone, and the National Electric Light Association has added another to its long list of successes. The attendance was good, the papers were excellent, the discussions were not too rambling, and the hospitality was as warm as the Southern heart could make it. As usual, a careful selection of officers was made. We had expected to see Mr. C. H. Wilmerding the choice for President, but all his admirable qualities were obscured by the unsupported belief that he might promote a policy favorable to the General Electric Co.; and the intense feeling on this subject led to the choice of Judge Armstong, who is understood not to be the wearer of anybody's collar. Since the honor has fallen to the East, we think that Mr. A. J. De Camp was well worthy of it. He is an old officer of the Association, represents large investments with credit, has always taken an active interest in the welfare of the Association, and has entertained it royally. We say all this without prejudice to Judge Armstrong, who is certainly one of the most brilliant and progressive of the younger men in the body, and who sees the deeper questions involved in the industry with which he is connected. His administration should prove highly prosperous and should lead the Association to a higher plane of influence and usefulness than it has ever occupied before.

It was the general hope that an earnest discussion might be had of the lamp situation. Town meetings cannot break Supreme Court decisions, but public opinion has been known to govern the enforcement of legal decrees and to shape not merely the policy of corporations but the acts of governments. Said President Cleveland in his inaugural address on Saturday last :—

> "The existence of immense aggregations of kindred enterprises and combinations of business interests, formed for the purpose of limiting production and fixing prices, is inconsistent with the fair field which ought to be opened to every independent activity. Legitimate strife in business should not be superseded by an enforced concession to the demands of combinations that have the power to destroy, nor should the people to be served lose the benefit of cheapness which usually results from wholesome competition. These aggregations and combinations frequently constitute conspiracies against the interests of the people, and in all their phases they are unnatural and opposed to our American sense of fairness. To the extent that they can be reached and restrained by Federal power, the general government should relieve our citizens from their interference and exactions."

That is exactly the feeling which a great many people in the electrical field and outside of it have about the General Electric Co., and it was uttered by not a few censorious tongues, in less measured phrase, at St. Louis. When the topic came up incidentally in the Convention, it provoked personalities, and the discussion, leading nowhither, was soon checked. It is absurd to suppose that such debate can do any good, but it had at least the merit of showing how strong and fierce is the undercurrent of opposition to the restrictive and monopolistic designs with which the General Electric Co. has been credited. That Company has valuable rights, and should enjoy them to the full; but there are other rights, and these will be stoutly protected against any assault it may make. To say that the antagonistic sentiment towards the Company, due to dislike and distrust, is so intense as to keep it on its good behavior should it intend to go wrong, is simply to state the truth. In the long run it may be shown that the Company has been unfairly prejudged. We sincerely hope so, for its own sake. The cares and perplexities resting on its able management are of no mean order, but they can be greatly reduced in the adoption and enunciation of liberal plans, to the approval and support of which all honest and true men will rally.

ELECTRICAL DEVELOPMENT IN ST. LOUIS.

Probably every visitor to St. Louis last week was impressed with the electrical activity of the city, and the great popularity of the trolley system of traction. The city has probably something under 600,000 inhabitants, yet the street railways, nearly all electric, collected 100,000,000 fares last year, showing an average of not less than 165 trips per person per year—a very high figure. There are about 300 miles of car line, and 50 more are building, and one of the trolley lines runs 20 miles out from the power house. Such progress does the city infinite credit, and we can say from practical experience that we wish New York had as good travel facilities as St. Louis has, thanks to electricity. The line construction and central station work inspected was also very good, reflecting most favorably on the administrative ability of Mr. Ayer and other managers operating plants in the city. It is this opportunity to see what others are doing that makes the conventions so valuable to the members who attend. Membership without participation in the proceedings is worth little compared with membership which wants something more than the reading of reports in electrical journals and the volumes of transactions. In this light, St. Louis is one of the finest object lessons that could be had.

UNDERGROUND CONDUITS AND CONDUCTORS AND THE EXPERIENCES OF ELECTRIC LIGHTING COMPANIES OF NEW YORK CITY.[1]

BY WM. H. BROWN

THOSE who are intimately acquainted with the histories of the electric lighting companies of New York City may be pardoned if they believe that the experiences undergone by these companies have been unique, and that they afford to companies elsewhere opportunities for beneficial consideration.

At the risk of presenting some incidents having the aroma of antiquity, or being tedious by the recital of what may perhaps now be considered well-worn tales, attention is invited to a statement as brief as possible of the story of electric lighting in New York City from the beginning to the present time.

In the years 1880 and 1881, but twelve or thirteen years ago, two companies began in New York City the business of distributing electric current from central stations for public and private illumination, the one using the Brush, the other the United States system of arc lighting.

In addition to the imperfect apparatus at their disposal other difficulties, the best medium then obtainable for the transmission of current of high potential was bare wire. With the progress that took place, however in the improvement of the conductor, improvements in the apparatus and appliances also appeared.

The extension of the use of electric illumination was not so rapid or so widespread as to call for many wires or very large poles. The operators of the company had not had such strong pecuniary inducements as to justify them in being very enthusiastic in looking to the possibilities of the future. They felt justified in restricting their efforts to satisfy such demands as were made upon them, and whenever a customer was obtained beyond the limits of the wires already erected the lines were extended with the least possible expense. The poles used were ordinarily 6 to 8 inches in diameter at the base, and 20 to 25 feet high, provided usually with a four-pin cross arm. A few of these poles have remained and are in existence at the present day.

In the year 1884 manufacturers of other apparatus saw in New York City a field of profit and advancement for their machinery. New York was the largest and richest city of the United States; the companies then doing business in that city were actually on the verge of paying dividends; and it could not be considered proper in the interests of the public that they should continue to have a monopoly. The result was that in the year 1884 franchises were granted to no less than six other companies, all of them primarily intended for arc lighting. Some of these companies, taking note of the numerous poles that were in existence for the telegraph, telephone, police and fire department service, deemed it uneconomical to erect poles for their own wires, but arrranged with those having charge of such poles for the attachment of the electric light conductors on these existing poles. Some of the companies erected in that year did not make rapid progress, and the increase of poles and wires for electric lighting was not materially appreciable until 1888.

In 1884 a bill was passed in the Legislature directing that the wires be removed from the streets before the first day of November, 1885, but it provided no means to insure their removal, nor penalties for non-removal. The Legislature of 1885 having found that the previous enactment had accomplished nothing passed another act which provided "that if no suitable plan should be proposed for placing the said wires underground, it should be the duty of the said Board of Commissioners to be caused to be devised and made ready for use such a general plan as would meet the requirements of the said Acts of 1884-5, and that the said Board should have full authority to compel all companies to use the subways prepared." Under this act the Subway Commissioners who had not been provided by the act with funds wherewith to carry out the object named in the act, deemed it wise, in order to carry out the purpose of the enactment, to make a contract with some company to build the subways, and did make such contract in 1886. Persons interested in the telephone company realized that the purpose of this act would inevitably be carried out; and as the interest of that company in the fulfillment of such purpose would be affected to a greater extent than any other, except possibly the telegraph company, they deemed it prudent to become interested in the company with whom the Subway Commissioners had made the contract for the construction of subways.

In 1888 began the introduction of the alternating system of incandescent lighting and four companies began a spirited effort for the introduction of incandescent lighting with the result of contracting for upwards of 60,000 lights within less than a year. This caused a considerable increase of wires. The wires were strung principally upon the poles previously in use. Comparatively few new poles were erected until in the latter part of 1888. The Board of Electrical Control, recognizing the increase of electric lighting, formulated rules for the extension of that business by means of overhead construction, and in order to provide the best possible overhead construction, prescribed certain requirements on which, with the immediate supervision of the Board of Electrical Control, what has probably been the finest line in the world was erected. It was considered an ideal line. It consisted of poles 85 feet high, 16 to 20 inches in diameter at the base, and not less than eight inches at the top.

During 1888 the companies having aerial lines in upper Broadway were directed to place cables in the conduits which had been prepared in that street and to remove their overhead construction, but they declared vigorously that it would be impossible to operate currents of high tension underground. The courts declared that the law gave to the Board of Electrical Control the power and the right to decide whether the subways were fit and proper for the purpose, and ruled that the companies must comply with the law and occupy their subways with their cables and remove their overhead construction.

In August, 1888, the first effort was made to use the electric light subways on Broadway from 14th to 135th streets. The Subway Company had invited the companies to make the experiment of operating high tension current underground and offered the use of the subways without rental for the experiment. The first cable was placed for arc service and consisted of eight conductors, insulated from each other and enclosed in lead armor. The experiment with this was not successful. The cable did not meet the requirement of the Board of Electrical Control of an insulation resistance of fifteen megohms per mile for each 100 volts for each conductor. This result seemed to verify the claims of the companies that arc lights could not be served from underground conductors under the conditions imposed and existing. The opposite view was maintained, however, by the Board of Electrical Control and its contractor company, and the courts having held that the law accepted no other decision than the opinion of the Board, the companies were threatened with the removal of their aerial wires in the localities provided with subways, whether they placed cables in the conduits or not.

The year of 1890 brought a new Mayor and President of the Board of Electrical Control. He immediately promulgated the order that within ninety days the wires must be removed by the companies from streets provided with subways or he would exercise the right given by the law to have them removed by the city, and as the order was not complied with, on the 5th day of April, 1889, the authorities began the cutting down of the electric light aerial lines on Broadway and Sixth avenue, where the subways had been provided.

Concert of action between the authorities and the companies; careful deliberation of the probable requirements and the energy which makes haste slowly but correctly would not have produced, it is true, the removal of the overhead line to the extent that was accomplished within practically two years; but also it would not have produced the extraordinary expenditure of money both by the Subway Company and the electric lighting companies, nor the loss of business and disturbance that occurred to the companies; but it is fair to presume that a somewhat different condition of the subway situations and of the electric light companies would have been effected with material benefits to all financially interested.

Mr. Browne then gave a number of statistics of underground work. These have already been covered in the recent articles by Mr. William Maver, Jr., in THE ELECTRICAL ENGINEER.

Nearly all the current for the high tension arc and incandescent service transmitted in the city of New York below the Harlem river is conveyed by underground cables. Above the Harlem river the Board of Electrical Control allows the construction of aerial lines, no subways having been built in that section of the city. Below the Harlem River no over-head wires are permitted to be erected and few of those that were in existence remain. It is probable that before the end of this year scarcely any will be in existence. The penalties endured by the companies for their opposition to the subways have been severe and drastic. The expense imposed upon them in their effort to take care of their business and meet the requirements of transferring their systems from overhead to underground has been enormous and burdensome. The expense for rentals, due in a large measure to the amount of subways constructed and not occupied, continues and seems likely to continue to be an enormous tax. Those expenses and burdens have tended and are likely to tend further in the future to confine the operations of the companies to territory contiguous to their generating stations, and may also tend to avoid the fierce competition which existed during the days of aerial transmission, and which lowered price to a point below remunerative rates.

If the subway situation in New York City was not such as it is, and it is such from the causes above suggested, there seems no no reason to doubt, in the light of the experience possessed by all conversant with the situation, that fully as satisfactory accommodations and results, could be accomplished at not exceeding 25 per cent. of what it has cost, and with corresponding beneficial conditions, which would prove, at least, not unremunerative to all interests affected.

May it not be concluded, in view of the experiences in New York City, that all aerial conductors are necessarily transitory, particularly in our large cities? Is it not advisable for controllers and managers of companies in such places to recognize that condition and endeavor to avoid the experiences of New York Companies by planning deliberately the procurement of the right to themselves to build and operate their own subways and further to utilize the experiences of New York to avoid the expensive mistakes there made and to place their business on a stable footing and in a position where they may have immunity from injurious and cheap competition and secure service to their customers free from the interruption belonging to aerial transmission? If the above recital of causes and effects, experiences and results, in New York City, will tend to prepare the way to avoid, to other companies, the experiences of those in New York City, the relator will feel as rewarded for his effort, as he is appreciative of the compliment implied by the invitation of our worthy President which has afforded the opportunity to offer it for your consideration.

---

[1] Abstract of a Paper read before the National Electric Light Association, St. Louis, Mo., Feb. 28-March 2, 1893.

THERMAL STORAGE FOR CENTRAL STATIONS.[1]

BY PROF. GEO. FORBES, F. R. S.

When asked to give you a paper on some electric lighting subject, it seemed to me that that I could not choose a better one than "Thermal Storage for Central Stations," which has had so much attention directed to it lately in England. It has long been evident that storage of some kind might lead to great economy in central station work. The reason of this is that the demand for light has in most cities a maximum for only two or three hours of the day. Not only do we require to have plant lying idle all the rest of the day, but the expense of working for these few hours is increased by its temporary character. This loss of economy has occurred both in engines and boilers. Underloaded engines are very inefficient and use up a lot of coal. This effect is, however, gotten over in all important central stations by having at least a few engines of small power to carry the day load. We are thus able to have engines in use always working at their most economical load that is, near full load.

The other loss in economy comes from the boilers which have to be fired up and heated only for a few hours' work and then banked or else allowed to cool down. This loss cannot be overcome by working the ordinary plant in any special manner. At the Kensington Station in London, where the engines are always working at an economical load, five pounds of coal are used per electrical horse power per hour, whereas in tests of 26 hours duration, made on the same plant with all the boilers doing full work, only three and a half pounds of coal were required for the same duty. If then we could have storage of any kind by which power is absorbed at times of light load and given off at times of heavy load, we should save one and a half pounds of coal per horse-power per hour. Many people have thought that storage batteries would overcome this trouble. It does so, but at an enormous capital expenditure on storage batteries, with a loss of twenty per cent. in the energy given to the batteries, and with a depreciation account which no one would put at a less figure than twelve per cent. per annum.

I have previously proposed that in a hilly country the boilers and engines should be working all the twenty-four hours, at the rate of the average demand, and they should be used to pump water through a pipe to a high reservoir at least five hundred feet above the pumping station. At the lower end of the pipe turbines are placed driving dynamos. During the day-time the reservoir is being filled and in the evening it is being emptied. This produces a saving in boilers and the substitution of cheap turbines and a small number of efficient pumping engines for a large number of less efficient engines to drive dynamos. It also reduces the coal consumption from five pounds to three pounds per horse-power per hour. In a paper read last year before the British Association for the Advancement of Science, I showed that this plan could easily be adopted in Edinburgh, in Scotland, the saving in capital and annual expenses being both very large. But it is not every city that has these advantages, and I wish now to introduce to your notice the excellent scheme which has been invented by Mr. Druitt Halpin of England.

He proposes to put up boilers only of the average capacity and to work them day and night. At times of light load the steam is carried through pipes into large iron reservoirs of cheap construction, and is used to heat up the water in these reservoirs to a high temperature and pressure. When the heavy demand comes on in the evening, steam is drawn from these reservoirs. The losses of heat from radiation from the reservoirs can be made very small indeed, with proper lagging; in fact, quite imperceptible.

This is the general scheme of Mr. Halpin's plan. But it has two advantages which are not so apparent at first sight. One is the purity of the water supplied to the boilers. Mr. Halpin pumps feed water into the hot reservoirs where impurities are precipitated in a place where they can do no harm. The boilers, on the other hand, are fed from this pure water in the reservoirs. The other incidental advantage of the system is that priming in the boilers does not cause any inconvenience, as the steam is all supplied to the engines from the reservoirs. Now it has been found from the experience with the water-tube boilers which are so much used in this country that only three pounds of coal per hour can be burned per square foot of heating surface on account of excessive priming, instead of the six pounds per square foot which we can use with the Cornish or Lancashire boilers, and which might be used with water-tube boilers if priming were no objection. Thus it appears that the adoption of Mr. Halpin's system not only reduces the number of boilers that we require, but also doubles the capacity of each boiler.

Mr. Halpin has worked out the relative cost of supplying machinery to the central station of Berlin (1) without any storage (2) with storage batteries, and (3) with thermal storage. He first selected this station because the output at each hour of the day all through the year was published before any other central station had published similar data. In this system there are four central stations, giving off about ten thousand electrical horse power.

The load at different times of the day is such as to lead to the following data:

Maximum load	7,500 kilowatts.
Mean load	2,030 "
Excess of max. above mean	5,080 "
Duration of ditto,	7.5 hours.

Now Mr. Halpin claims that he can replace 22 boilers for working in the ordinary way by five boilers and 92 of his storage cylinders, which are cheap to construct and have necessarily a small evaporation. His claim, which I must admit seems to be quite well founded, is that while laying out somewhat more capital on his plan, he gets a very large return for the extra capital spent. He sums up the cost of the thermal storage system as follows:

5 Babcock & Wilcox Boilers,	$27,050.00
Boiler House,	9,500.00
Chimney,	4,850.00
Cylinder House,	33,300.00
92 Cylinders,	184,000.00
Total,	258,700 00

and he puts the cost under the existing system at $182,700.00.

Now if we charge 10 per cent. to annual depreciation of boilers and only five per cent. on the iron cylinders, which really seems a very fair value, then the annual interest and depreciation comes out almost the same for both systems, thus:

Existing System.	
5 per cent, on $182,700.00 capital,	$ 9,135.00
10 " " " 117.850 boilers,	11,785.00
4 " " " 64,850.00 buildings,	2,600.00
Total,	$23,520.00
Thermal Storage.	
5 per cent on 258,700.00 capital,	$12,935.00
10 " " " 27,050 boilers	2,705,00
4 " " " 47,050.00 buildings,	1,900.00
5 " " " 18,400 cylinders.	9,200.00
Total,	$26,740.00

Annual charges against thermal storage, $3,220.00, but the annual saving in coal is, in this special case, 7,000 tons, besides the saving in ash removals and firing. Mr. Halpin thus obtains figures, giving an annual saving of $36,530.00, to pay interest on extra capital of $75,000.00, with coal about $5.00 per ton.

Now the only kind of storage against which Mr. Halpin has to compete, when high land is not available for utilizing water storage, is the storage battery; and from his figures, which seem fair to me, the extra capital required is $732,200.00, and the total annual extra cost, $110,750 00, which shows a great advantage in thermal storage.

I consider that all these figures are very conservative, and that in these days when we are learning to realize the importance of cutting down working expenses in central stations, this system must necessarily occupy an important place. But it is of peculiar interest to me, owing to its applicability to a kind of work to which I have devoted a large part of my time in the last seven or eight years. I refer to the burning of the house refuse and garbage in our cities. The furnaces in which this cremation is accomplished are generally called "Destructors". It has been one of the great objects before me of late years to have this title abolished, and to justify their being called "Utilizers". The improvements which we have introduced in the methods of burning refuse are so great that I can now undertake to produce the following results:—

Taking the ordinary house refuse, ashes, coal, wood, paper, old books, vegetables, bones and scraps, crockery, tin cans, iron posts, bottles, and adding thereto occasionally dead cats and dogs, infected mattresses and condemned meat, I can throw the whole of these, without sorting, upon the furnace, and without producing any offensive odors or dust I can raise the temperature of the gases where they reach the boilers to over 2000 degrees Fahrenheit. From my data as to the amount collected in different houses in England per head of the population, I find that from the house refuse of any town I can supply steam enough to generate electric light at the rate of one 16 candle-power lamp per head of the population for two hours every night of the year. By doing this I am saving the municipality from $10,000 to $20,000 per annum per 100,000 inhabitants for the cost of removal of house refuse. I am preventing these objectionable materials from being dumped in the outskirts of the city, where building operations will soon commence, or in the neigboring harbors or lakes, either of which plan is a nuisance and unhealthy. The only resulting material is a clinker, which can be broken up, and which when mixed with cement makes admirable concrete or artificial stone for paving, while by itself it makes excellent foundations for roads.

---

[1] Read before the National Electric Light Association, St. Louis, Feb. 28-March 2, 1893.

Now these enomorous advantages, of the truth of which we have ample proof from a practice extending over nearly twenty years in England, can be worked at full economy only when the burning of refuse is quite continuous and uniform. To do this we must have storage of some kind. In hilly countries the plan I have advocated of water storage is generally available, and is very economical. In all other cases thermal storage is far and away the most economical mode of working, and in this line alone, if in no other, I have always said, from the first moment I knew of Mr. Halpin's invention, that we have here the last item which was wanting in order to do away with the barbarous methods generally adopted for getting rid of house refuse, and at the same time utilizing that refuse in a manner that will confer material benefits on all the inhabitants of a great town, and pecuniary advantage on those who undertake the work.

PROCEEDINGS OF THE SIXTEENTH MEETING OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

FEBRUARY 28, 1892.—MORNING SESSION.

THE meeting was called to order in the Telephone Building by **PRESIDENT AYER**, who introduced Mayor Noonan, of St. Louis, who welcomed the Association to the city.

PRESIDENT AYER then delivered the following address:

PRESIDENT AYER'S ADDRESS.

At this, our sixteenth convention, it gives me much pleasure to receive you in a city which can display such an appreciation of the work in which we are engaged; to welcome you in my home and be able to present to you the attractive programme that has been prepared.

Since the first meeting in 1885 at our sister city by the lakes, we have spread upon our records evidence of the wonderful progress of the great industry we represent, and while as measured by time the years are few, the progress is marvelous. No art, no industry, no science can compare with it; and in no more forcible manner can it be represented than by stating that there is more capital invested in St. Louis in the application of electricity to-day than the sum total of investment throughout the United States for the production of apparatus and its use when this Association was born. These are facts well known, yet hardly realized by those of us who are engaged in promoting this remarkable development. In St. Louis we have enstalled 266 dynamos in central stations and various private plants, supplying current to 185,000 incandescent and 5,330 arc lamps; a total of 1,800 h. p. capacity of generators, supplying 660 motors for operating almost every character of machinery, and 8,240 h. p. in generators, operating 1,126 street car motors, over 160 miles of road; and the roads under construction, to be completed within the year, will add 8,000 h. p. in capacity and 96 miles of road. This will make a total generating capacity of 30,000 h. p.

There are nearly sixty square miles of territory supplied with arc and incandescent lights, and which is crossed and re-crossed with electric roads. The changing from steam and cable to electricity for motive power has transformed a bankrupt road into a most valuable property, and successful cable roads are to be changed at much expense to electric, that they may be more successful. This exposition of the development of this industry is what St. Louis has to offer for your inspection.

Since our last meeting much has transpired of interest to the members of the Association. Important developments have been announced from time to time through the press, as the result of the work of inventors, and many valuable items of detail have been brought out to add to the efficiency and satisfactory working of existing apparatus. The commercial development, however, has been confined to improvements in well-known apparatus and not to radical departures in character of generators as many were led to expect a year ago. More light will doubtless be given us in this direction through some of the papers we will be favored with, but there seems to be little likelihood of the introduction of new methods soon which will affect the quality of investments in existing apparatus, though there is reason to expect in the very near future that which will likely solve the problem of long distance transmission in a satisfactory manner. The much desired power motor for simple alternating circuits we are still anxiously looking for, and for some applications such motors as are known to be practical should be produced.

The recent patent decisions have introduced a new condition to many, brought anxiety and trouble to some and satisfaction to others. To those of us who were lulled into security by the tedious delays of the courts and the persuasive arguments of our friend, the salesman, who had so many advantages to offer, comes anxiety. To those of us who have only recently entered the field, and who heard very little of claims for "foundation patents," it is a new condition we can hardly realize, and we doubt its reality; and we are strengthened in our doubt by those who do not want it so. To those of us who consider carefully and believe in the ultimate establishment of the inventors' claims and rights, and who gave evidence in support of this faith by paying, in addition to a fair market price for the apparatus, an additional sum for the right to use it, and who have waited many years to receive the protection we paid for, comes the following satisfaction:

That such a condition as exists to-day can be brought about calls for prompt action, that the rights of the people may be better protected. That the inventor can be so long deprived of his rights that many are led to believe by the delay that he has none, and to such an extent that millions are invested in developing a business made possible by his invention, without regard to his claims, is clear evidence of the need of reform in our laws which will provide adequate protection for the investor, as well as the inventor; and we earnestly recommend some action on the part of this association, that our properties which have been so long regarded with distrust and suspicion by the financial world may not have added to their burdens the question of their right to use devices which are vital to their success; and to so place the station manager that he must not add to his other essential qualifications that of being able to divine what the courts may do in the far future. At previous conventions this topic has been considered and efforts made to have Congress take such action as would give relief. Work in this direction should be taken up again by this body and vigorously pushed to completion.

I note with much pleasure that since our most interesting and delightful visit to Montreal, most rapid advancements in electrical interests have followed, and that the Canadian Electrical Society has at a recent meeting given much evidence of remarkable growth. That, with the greatly increased business of our electrical manufacturers, notwithstanding the protection wall over which their "heavy" products have to be lifted, indicates that our time was well spent; that there was developed a friendlier feeling and closer intimacy, besides giving an impetus to electrical development for which they seemed to have been waiting. I believe our visit has done much to hasten the time when there will be no wall between one country and one people.

The preparation for the World's Fair is rapidly nearing completion, and in a few short weeks there will be opened to the visitor one of the most magnificent achievements of modern times—an engineering and architectural wonder. In no particular is it more remarkable than in the department of electricity. This in its ramification permeates all departments and will make possible most marvelously beautiful effects, as well as prove the most useful of servants. Too much praise cannot be awarded those who have labored to produce this most complete exposition of the development of the science in all its forms.

The American Institute of Electrical Engineers is doing much to assist in the arrangements for a fitting meeting of the electricians of the world, and our committee will present a report which, with the information received from a representative of the World's Fair, will enable us to act in the best manner to show the national and patriotic character of our organization.

In the past year much work has been accomplished by our secretary, and the showing for the year will, I feel, be very satisfactory when his report is read. Three volumes of the association's proceedings have been edited, published and delivered to members within the year, bringing this work down to date. Because of the accumulation and the large amount of matter contained in each volume this has been no small task, and the creditable results obtained in the handsome volumes, together with the thorough manner in which the office has been conducted, make it but a simple act of justice that I express my thanks and commendation at this time.

The interest in the proceedings of the convention evinced by the educational institutions throughout the country is one of the encouraging signs of the times, and justifies the statement (which is evidenced in many other ways) that the power and influence of the association are extending. The increase of membership is flattering. With this condition existing there will come up for your final consideration the question relative to the reduction of dues. While present conditions indicate that we can with safety reduce our dues, and possibly increase the membership beyond its natural growth under the present rate, yet there is much work which can be carried out to the benefit of the association which would have to be neglected if our revenue is reduced. The dues at present are hardly a burden, and a balance on the right side of the ledger is essential to the prosperity of any institution. While a change in the dues would not affect our treasury for more than a year, during which there will be extra expenses on account of the meeting which will necessarily have to be held in Chicago, I do not think it wise to reduce them at present. This question I trust will receive due consideration before action is taken.

From the beginning until to-day every producer and operator in the electrical field has had before him the serious problem of how to get men sufficiently skilled to execute in a satisfactory manner the duties assigned them. Undoubtedly this business has attracted in all departments the most ambitious elements from other lines of work, but as we can all testify, their education in the new field has been enormously expensive to their employers. But the future outlook is promising. While within the past three years this army has more than doubled, and the new element had little or no previous training or knowledge of the work, yet there have been established more rapidly than ever clubs, societies, trade guilds and labor organizations, with the principal avowed object of self-education. Their objects and efforts in this line are to be commended, and form a pertinent topic for this body to consider. In St. Louis we have among societies of this class, an organization known as the Electrical Exchange, composed principally of contractors whose particular business is to do electrical construction required in all modern buildings. Their prime object in organizing was, that the execution of this work might be confined to those who were responsible and maintained regular establishments. Their endeavor is to so execute the work entrusted to them that they may command the respect and confidence of the central station manager, owner, architect and builder. To this end they meet for discussing improved methods, and such other matter as may be suggested and calculated to be of mutual benefit. Insurance inspectors, supply houses and central station companies are eligible to membership. In contact with them we find them ever ready to coöperate with us in any movement to improve the service and increase the satisfaction of our customers; and since their organization a much better feeling has been established and the quality of work greatly improved.

Within the past year has been organized the National Association of Electrical Workers, with headquarters in this city, and having branches in many towns and cities. This organization is largely composed of linemen, though it expects to embrace in its membership electrical artisans or workers in every department. Their principal object is, as stated, in the first number of their journal, is to band themselves together for mutual education and improvement; to establish rooms and provide instructors, and adopt such other methods as may improve the standard of electrical labor. This organization is capable of accomplishing a vast amount of good, if maintained on the high plane outlined. If the effort is earnest and honest we can all lend then a helping hand and will do it gladly. The wage question will never be an element to make a breach when the rank and file of electrical workers have mastered their business. But until that time arrives those who are among them as leaders should keep in mind that satisfactory work, performed in a conscientious manner is the first essential to pleasant mutual relations between the employer and the employed, as well as the strongest lever to raise wages that can be produced.

Thoughtful care on the part of the manager must be given that the man who climbs the pole to clear a ground or close a circuit, in the sleet and rain, and all others as well, be protected by all safeguards in the way of instructions and appliances that can be suggested. The engineer, the dynamo tender, the lamp trimmer, all must be encouraged in their efforts to improve in knowledge, by active coöperation on the part of the management. A close acquaintance with our employés is an essential to a full appreciation of their services. Many acts of heroism are performed by the lineman or the dynamo tender, in order that the service may not be interrupted, and that, many times, without a passing mention. We can shake out the crosses and clear the grounds by a closer acquaintance with our men and their work.

During the year that has passed, death has claimed an unusual number whose names have been prominently identified with the active promotion, development and application of electricity in its various branches. Those particularly interested in the department devoted to telegraphy were, Cyrus W. Field, Wilson G. Hunt, F. N. Gisborne, Jay Gould and Norvin Green. In electric lighting and railways, C. J. Van Depoele, E. T. Lynch, Jr., M. M. Slattery, and in Europe, Werner von Siemens. In this list are the names of those who have borne much of the heat and burden of the day and were among the few pioneers who hewed the part and assisted to broaden the road, by overcoming difficulties which we, who find it so comparatively smooth to-day, little appreciate.

To our guests who have assembled with us and honored us by their presence, and who will further honor and instruct us with their words of wisdom, I want to express our thanks; and I trust that the members will by their presence at the different sessions demonstrate the sincerity of this expression on their behalf.

At the conclusion of his address, the president declared the Sixteenth Convention of the National Electric Light Association formally opened, and the paper by Mr. A. D. Adams on "Wrought versus Cast Iron for Field Magnet Frames" was then read.[1]

There was no discussion on this paper. The secretary made several announcements, and read letters of regret, as well as a number of invitations extending courtesies to the Association.

An invitation to hold the next meeting of the Association in Omaha, Neb., was read from Hon. G. P. Bemis, Mayor of Omaha.

Mr. E. A. Armstrong then read the report of the committee on the World's Columbian Fair, the chairman B. E. Sunny not being present.

REPORT OF THE WORLD'S COLUMBIAN EXPOSITION COMMITTEE.

The Paris Exposition of 1881 was lighted in part by 1,383 arc lights, and was the first arc-lighted exposition. The Louisville Exposition of 1882 was lighted by 5,000 incandescent lights of 15 c. p. each, and was the first use of incandescents for exposition lighting. The New Orleans Exposition was lighted by both arc and incandescent.

The Paris Exposition of 1889 made the largest use of electricity up to that time. There were for public lighting service 1,093 arcs and 8,837 incandescents. For private lighting there were used 623 arcs and 4,010 incandescents. The total of the service installation aggregated 3,125 h. p. capacity, and, with small installations, the grand aggregate capacity reached nearly nearly 4,000 h. p. There was practically no use made of electricity as a motive power.

The World's Columbian Exposition has placed contracts for 4,500 arc lights, of 2,000 nominal c. p. each, and received donations from miscellaneous exhibitors of about 700 additional. They have placed contracts for about 80,000 incandescent lights and received donations as special exhibits of about 10,000 additional. They have placed contracts for 2,900 h. p. capacity of power generators and received donations of 1,600 h. p. capacity. They have made contracts for electrical fountains requiring an installation of 900 h. p. capacity. The aggregate of power generators and fountain plant (the latter will be used particularly for charging the storage batteries of the electrical launches) is 5,300 h. p.

The total aggregate of the electrical installation therefore, amounts to 19,500 h. p. The total aggregate of boiler capacity employed is 18,000 h. p. on the standard rating of 30 pounds of steam per horse power per hour. With such efficiency as should be expected from the engines installed, this represents an effective total of about 24,000 h. p.

The most interesting point of this plant will be the use of oil as a fuel. From the time the crude petroleum is emptied from the railroad tank cars into the World's Fair storage tanks, at the extreme southeast corner of the grounds, this oil becomes part of the power plant, the pressure upon the delivery pipe being automatically controlled by the steam pressure in the boilers. Delivery to boilers is made by pipes laid underground from the storage tanks to the boiler house, and the oil is introduced into the furnace in an atomized jet.

A point of exceeding interest in the engine and dynamo room will be the very large adaptation of dynamos to Corliss and medium speed types of engines in direct-connected combinations. The largest of these will be a set of vertical triple-expansion engines with two connected armatures. At 60 pounds steam pressure this single unit will give most economically 1,200 h. p., with a capacity for continued service of 1,500 h. p. output.

Next to the universal distribution of electric power for all points of the grounds, the most marked advance of the time is the application of electricity to the transportation service of the Exposition. This service will be by a three mile double track elevated railroad following all the precedents and best practices in block signalling systems, power brakes and all other safeguards of the modern steam railroad used in exclusively passenger traffic. The entire operation will be, however, by electric power drawn from an independent power plant of more than the aggregate capacity installed at the Paris Exposition. In this power house will be found the latest examples of the large range of direct driven power generators, five in number, and aggregating 3,500 h. p. capacity. To those who have not had an opportunity of informing themselves of the part that electricity is expected to play at the Exposition, these figures will be interesting and will indicate to all how much greater by comparison with preceding expositions the Columbian Exposition is bound to be.

The sensational reports telegraphed from New York that many of the prominent electrical firms in that State had decided to abandon the space allotted to them and make no exhibit, were found on inquiry to be based on the fact that three small concerns had gone out for reasons that were personal to them. Every foot of space in the great building has been taken and every electrical concern of any consequence in the world will be fully represented. The active work of preparing for the exhibits has been going forward for some weeks and many of the electrical firms have made substantial progress in the erection of their booths.

The intellectual programme to be carried out under the auspices of the World's Columbian Auxilliary promises to be of remarkable interest. As you know, Prof. Elisha Gray is at the head of the electrical branch and he now has assurance that the gathering of electricians from all parts of the world will be a grand one.

At the conclusion of the reading of the foregoing report, the meeting adjourned until two o'clock.

---

[1] See page 232.

TUESDAY AFTERNON SESSION.

The first business of the session was the reading of the paper on "Relation of Insurance to Electric Lighting and Power," by Mr. William Brophy.[1]

Mr. Hammer—It seems to me in view of Mr. Brophy's remarks that it is possible a closer union could be established between the National Board of Fire Underwriter's and the men who are actively engaged in the electric light enterprises, by having a joint committee composed of members of the National Board of Fire Underwriters and of the National Electric Light Association, who come together and compare notes and have a report issued which would be a joint report. From what the Chairman of the Board of Fire Underwriters told me there is a feeling of considerable jealousy on the part of that Board as regards the report issued by the National Electric Light Association. They feel that they should not be dictated to by this Association, and naturally enough we feel that we should not be dictated to by them.

Capt. Brophy—I have no objection to any rules that may be made by the Board of Fire Underwriters, so long as they do not exact undue concessions or place undue restrictions on the business. I have lately come into possession of certain rules issued by the National Insurance Board, as they style themselves. They vary but slightly from the rules issued by this Association; and I really recognize my own work in them. I suggest that our standing committee on safe-wiring before the next meeting compare these two rules, and if possible, work in harmony with the insurance companies; there is no occasion for having two sets of rules, or having any misunderstanding about them.

Mr. M. J. Francisco said he had been an insurance adjuster for about twenty-five years, and knew something about the knowledge which most of the insurance agents had about the electric lighting business. Nine-tenths of them do not pretend to know anything about the electrical part of the business. There were a few insurance men that understood it. The high rates were the result of the loose way of construction and arrangement which prevailed in many places. He would never place a dynamo on a flooring of timber; he would have a stone or brick floor laid in cement and place the dynamos on that. He could stand in one position in his station and see every wire in it.

Mr. A. J. DeCamp thought it might be impossible to adopt a rigid set of rules and make them apply to all stations alike. A rule that could be applied to the station which Mr. Francisco had just described might not be applicable to a station at another point. It had therefore occurred to him that it might be a good plan, instead of having the committee meet to consider and adopt the Montreal rules, to have it resolve itself into an arbitrating committee.

Mr. H. G. Issertel inquired why these rules are not universally accepted. He had found in certain cities of the same state a certain set of rules and in another city, especially in Pennsylvania, another set, entirely different, in vogue. He had found that many central station men were so disgusted with the way these rules were being handled that they give them very little attention.

Mr. E. A. Armstrong' thought the underwriters were the ones who should make the rules.

Capt. Brophy in reply to a question from Mr. De Camp said that he had had a large experience formulating rules; and it was his judgment that a rule was never yet made that would not be deviated from. There must be some discretion left to the constructor, to the man who is furnishing light, or to the insurance inspector. For this very reason, the committee was a standing committee, so that they could at any time add to, or change, or modify the rules, whenever it became necessary.

The paper by Mr. R. H. Sterling was then read on "Some Experiences with the Alternating System."

Mr. Sterling being called upon for a full explanation of the "booster" referred to in his paper, said that Mr. Wagner could explain it fully.

Mr. Wagner:—Mr. L. B. Stillwell is the inventor of the arrangement called the "booster," or more properly, the Stillwell regulator. It is rather difficult to explain it without the use of a diagram or blackboard. It is simply a converter arrangement used to raise the potential at will on any circuit or feeder, by means of a series of contacts usually differing about one per cent. The regulator as usually constructed may be used to raise the potential on any feeder from one to twenty per cent. It is a simple converter with ordinary coil connected in the usual way in multiple with the circuit or shunt to the secondary coil, which is adjustable in length, or has a number of ends brought out, placed in series with one leg of the feeder, and adding its potential to that of the line or the dynamo.

Mr. De Camp inquired as to the relative value of the alternating system, within a prescribed circuit, say of one or two miles, as compared with the direct system, with the machines coupled in multiple?

Mr. Wagner replied that as to the flexibility of the alternating system, and the possibility of using the station units to their utmost capacity, he had never in his practice found it necessary to run any station unit under seventy-five or eighty per cent. of its total capacity. By a very simple switchboard arrangement it is possible to connect as many circuits to one dynamo as is desirable, and as the load falls off the station, the units or dynamos are shut down and the feeders are gradually brought together on a few number of dynamos, and in that way the station apparatus can be used as economically and advantageously as with direct current. He coupled the circuits together instead of coupling the machines together, and that can be done without interrupting the service for even a moment on any circuit. It had now become possible to run arc lamps as well as motors on the alternating circuits, and he thought that it had at last become almost universally conceded that for most purposes the alternating current was as flexible as the direct current. In St. Louis they covered an area extending six or seven miles from the station in several directions. The station was situated almost at the centre of the district, in which they had between seventy-five and eighty thousand lights; they had never had any trouble from want of flexibility of machines or circuits.

Capt. Brophy thought that much trouble was caused by running, say, four or five circuits, none of which had the same loss; these would now be coupled together and do satisfactory work.

Mr. Wagner remarked that it was just as possible with alternating circuits as with direct circuits to use feeder regulators. In a properly constructed alternating system it was just as necessary to use a system of feeders and mains as with the direct system. Generally the same devices could be used for regulating either current; but the Stillwell regulator was a device which could only be used on alternating circuits, and was much more economical to use than any other form of feeder regulator, using resistance, as this regulator raised the potential of any one circuit instead of lowering it. The circuits with small amount of drop are left as they are, and those with greater load are raised in potential sufficient to bring the potential at the end of the feeder to the proper standard. It was customary in direct current systems to connect all the feeders and mains together, forming a complete and continuous network. It is claimed as an advantage for the purpose of keeping a uniform pressure throughout the system. In the speaker's opinion it was a distinct disadvantage in case of ground or trouble occurring on the line, as it then became very difficult to locate it. In the alternating system it was used to keep each feeder and its system of mains entirely separate outside of the station, simply throwing them together in the station. Any trouble occurring on one of the circuits is immediately indicated by the station instruments or fuses, and is located and confined to quite a small district. In the case of the Missouri Electric Light Company the loss in feeders varied from five to ten per cent.; the average probably being about eight per cent.; six per cent. in the feeders and two per cent. in the mains. It depended on the proportion between the average load and the maximum load. That differs at different seasons of the year.

Mr. Edward Weston: I do not think anyone is in a position to fully answer the question of loss raised by Mr. De Camp, namely, which is the more economical of the two systems. The systems as established here differ radically, in one respect at least, from the systems established on the other side. Here, for the purpose of economy in the first cost, a very high rate of alternation has been adopted. From present experience it seems as though this was a fundamental mistake, and that the mistake will be more apparent as the system has to be forced underground, which will come sooner or later. We must all recognize the fact that any system of aerial conductors can never give us the safe and sure service which is necessary to enable us to compete with a satisfactory and reliable source of illumination such as gas. If our alternating current systems of this country were forced underground, the loss would be, undoubtedly, greatly increased; but what the losses are exactly at present, I have not been able to find out.

The constant growth of the alternating current system indicates, however, one thing surely, namely, that it is filling a long-felt want and that it is a money-making investment at least, for a large number of people. Whether the system as it exists in this country to-day will not be radically modified in the next few years so as to approach more closely the systems of Europe is a question; but' I think it will. I think that will undoubtedly be done and the tendency will be toward a lower rate of alternation and greater general efficiency. Of course, you can get a general idea of the efficiency of the alternating system by keeping records of the total output per hour as indicated by the instruments, supposing them to be reliable, and then summing these up at the end of the month, or at shorter periods, if possible, ascertaining what your wattmeters or recording instruments indicate. You would have a rough check in that way. I noticed one remark in the paper in regard to the use of instruments. Instruments are generally placed on the switchboard, and quite frequently so near to the other apparatus as to make their indications unreliable. The speaker then mentioned a case in which the voltmeters on a switchboard were affected by a bus-bar two inches behind them carrying 1,000 amperes direct current.

Mr. G. H. Blaxter inquired whether in going underground with the alternating system the loss would be greater with the high number of alternations than with the overhead system. Mr. Weston replied that he should expect the loss to be greater on account of the inductive influences. He also thought that the concentric system of wiring met with serious difficulties, and that it would be found that there is a greater loss underground.

---

[1] See p. 230.

Mr. Blaxter in reply to a question from Mr. Hammer said that comparing the alternating circuit with the direct current, he had not noticed any difference in the life of the lamps; but one thing he had noticed, and that is, that a lamp in the city in a store would burn out in a less number of hours than a lamp in a residence. Vibration, he thought, had something to do with it. He thought the shaking of buildings in the city had a serious effect on the life of lamps.

Mr. Ch. Wirt thought the difference in the life of lamps in stores and residences could be accounted for by the fact that the residence is generally further from the centre of distribution and the pressure is generally lower. He had made tests of that kind, and thought it pretty safe to say that was the usual state of the case. Regarding the difference in the life of lamps on the alternating and direct current, he thought that question had almost been settled by laboratory tests and results of large experience; the results having shown that there is practically no difference between the two.

Mr. E. G. Kilbourne—The question as to the relative value of the two systems depends largely on the field you are going to operate in. In Seattle we have both systems, and find they do not conflict; and we also find the alternating system just as flexible, and in some respects more flexible than the direct system. If you have a station which is so situated that you do not expect to go beyond a certain limited distance from the station, and your load is liable to be light at certain times of the day, and you want to run all day, there is no question that the direct current is the better and cheaper. The chronic condition of most stations is light load, and the direct system under these conditions is the more economical; but it is impossible to go beyond a certain distance with the direct current, so I think the question largely solves itself.

WEDNESDAY MARCH 1.—MORNING SESSION.

President Ayer called the meeting to order and announced the first business to be the paper by Prof. George Forbes, of London, on "Thermal Storage for Central Stations.[1]

Dr. Louis Bell thought that Prof. Forbes' plan of storing water power is one that can be worked successfully, quite aside from the matter of thermal storage and that thermal storage itself was a matter to which we should give our very careful attention.

Prof. Forbes in answer to questions gave the details of the Halpin system described in The Electrical Engineer of Feb. 22, 1892. In answer to a question as to the relative efficiency or cost of the system of the storage of water, which he and Prof. Forbes proposed, and that of thermal storage, which Mr. Halpin has proposed, Prof. Forbes stated that the running expense is almost the same in the two; but the economy of capital, if the reservoir is anywhere near the pumping station, is very much in favor of the water storage. The water storage takes off about 30 per cent. from the cost of a central station built upon the ordinary lines. That was so in the detailed plans which he worked out for the city of Edinburgh, Scotland. The thermal storage plant was rather more expensive to erect, but the annual saving on these two systems was about the same. In the old-fashioned method of building destructors it took ten pounds of refuse to produce the effect of one pound of good Welsh coal. Now they had reduced that quantity down to about five or six pounds of refuse to be equivalent to one pound of coal.

Mr. T. Carpenter Smith remarked that the boilers of hoisting engines were able to do work far in excess of the normal capacity of the boiler on account of the storage of heat in the water, similar to the principle of the Halpin system. The greatest doubt in his mind as to the success of this storage system was that identically the same thing had been tried in Boston, where a company was formed for the purpose of distributing power by hot water, called liquid steam, which simply meant water at a pressure and temperature corresponding to about 400 pounds. This water was carried through pipes, and when it was desired to use it in any building, the moment it escaped it became steam. The practical working of the plant was first-rate. The thing collapsed, however, through an unexpected difficulty; and that was the tremendous and rapid destruction of the pipes from the continual use in them of the highly-heated water. How that would affect a plant of this kind where one could use steel pipes he did not know. Perhaps Prof. Forbes could give them some information on that point.

Mr. Ch. Wirt drew attention to the so-called fireless steam locomotives in service in Chicago for many years, which were charged at one end with hot water under high pressure from an ordinary stationary steam boiler. He also inquired why the storage battery failed in comparison with steam storage.

Prof. Forbes—I made a direct comparison between the cost of batteries and of the thermal storage system. The loss in connection with the storage battery includes increased original expenditure in putting down storage batteries, which is far greater than the dynamos and machinery they replace, and also the great loss of efficiency—80 per cent. being the efficiency at which they work, there being a loss of 20 per cent. of coal; and also the depreciation account, which I think every one must admit is about twelve per cent. per annum. I have installed numerous storage batteries, but have never done so in a central station. I have done my best to try to find an economy in them, and if it were feasible, would have recommended them for central stations; but I have never found that batteries introduced in central stations would be a large economy. I know there are others who hold different views; but my experience leads me to the belief expressed. Storage batteries have their appropriate places, and I would like to see them much more used than at present in this country. There are a number of storage batteries of the Planté type that are available, and yet no one seems to work at them here.

Mr. L. B. Stillwell—The central station man who is paying for energy in the form of coal and selling it in the form of light is losing various amounts at each step of the process, but up to the present time he is losing far more before it gets to the dynamo than he is after it leaves the dynamo. I estimate that out of 1,000 h. p. that the central station man buys in the form of energy in coal, he may be able to sell two and eight-tenths in the form of light. He has lost in the various stops about 980 h. p. before he has reached the dynamo. In the electrical apparatus down to the lamp he loses, the remainder. I am glad to know that the steam engineers are attacking this problem of waste energy in the steam plants in a way that promises success.

Mr. T. C. Smith thought there was little to be gained by the use of storage batteries owing to the loss of 20 per cent., and because it would require the same amount of attendance as an engine and dynamo.

Prof. Forbes replied that a person of ordinary intelligence could be instructed in the care of the batteries in a few hours, and often this duty falls to the carpenter, or gardener, or even butler, on some of the large estates. Even in the larger plants, he did not think it necessary to have any one in constant service; but had instituted a system of daily and weekly inspection of the apparatus to see that everything worked efficiently, and to supply defective parts, and on the whole they met with much success.

Dr. Louis Bell thought that one reason why the storage battery had been such a failure on this side of the Atlantic was because it had been exploited from the time it first made its appearance here for the purpose of street car traction or other purposes to which it was least adapted.

Mr. W. J. Hammer thought another reason was that in England, France and Germany they use accumulators about the size of a trunk. Probably the small depreciation and commercial character of these accumulators was to a considerable extent due to the massiveness and the mechanical strength of the plates, and the cases in which the accumulator plates are placed.

Prof. Forbes remarked that the smaller cells, as long as they were large enough to be made in a solid, mechanical manner, lasted just as well, and their efficiency was relatively just as good as the large ones.

The convention then adjourned until two o'clock, P. M.

WEDNESDAY AFTERNOON SESSION.

The session was opened by the reading of three kindred papers as follows:

"Long Distance Transmission of Power,"[1] by Mr. C. S. Bradley; "Power Transmission for Central Stations,"[2] by Dr. Louis Bell; and "Under What Conditions is the Use of Water Power Economical?"[3] by Mr. L. B. Stillwell. These were discussed jointly.

Mr. W. J. Hammer, referring to the statement of Dr. Bell, that it was not practicable to use multi-phase machines of over 1,200 volts, reminded him of the fact that direct current machines were in daily operation at 3,000 volts and more. Moreover, Prof. Crocker had been running for some time direct current machines of 5,000 or 6,000 volts without any difficulty whatever. He did not think Dr. Bell had placed enough importance upon the application of the motor transformer in this country. It would be interesting to know just why alternating motors of large capacity were not in use.

Dr. Bell in reply said that he had stated in the paper that high voltage could not be used requiring the employment of 1,200 volts or thereabouts if the machine is designed to carry large currents. Experience up to date had shown that they would not work satisfactorily for any length of time. As to the direct current transformer he was very far from desiring to belittle it. The transformer which takes a current at 1,000 or 2,000 volts and brings it down to 100 or 200 volts may have a very direct application after we get the high voltage machine. But the tri-phase multiple transformer was very much more simple and efficient than the machine which takes a high voltage direct current and transforms it to a low voltage direct current. As to why alternating current motors in large sizes have not been used up to the present time, he thought the principal reason was that there had been no very large call for long transmissions until quite recently. It was perfectly practicable to run large synchronous motors; a matter about which there was no difficulty, and when occasion had arisen it had been done.

---

[1] See p. 242.

[1] See page 236. [2] See page 238. [3] See page 235.

Mr. L. B. Stillwell remarked that the tri-phase system effected a reduction of about 14 per cent. in the amount of copper for the transmission circuits over that required by a two-phase system. But that did not mean that we must increase the potential by any such amount as 14 per cent. in order to come back to even terms on the copper expenditure. It was sufficient to go up about seven or eight per cent. The points on which the two-phase is distinctly and positively superior to the three-phase or any multiple system, were first that the two-phase required just two transformers at every point where the three-phase required three. To a practical man, this was sufficient to overrule all of the arguments in favor of the three-phase that had been advanced, assuming all of them to be correct. For a general transmission and distribution project where we must supply power for lighting and street railway and general purposes, we must abandon the single phase; we must produce a difference of phase in some way, and having done that, it seemed very desirable to stop at the simplest form of the multi-phase, namely, the two-phase apparatus.

Mr. C. S. Bradley stated that he had tried to build such alternating motors and had not been able to do it. He succeeded in building a 1 to 2 h. p. motor to work on a single-phase alternating circuit which had an efficiency of 52 per cent. He had never been able to construct one without a commutator, and wherever a commutator was used the sparking was excessive. If it was not bad when the motor is first started, after a few hours it became very bad.

Mr. Edward Weston did not agree with Dr. Bell in the statement that 1,000 volts was the limit of work for the direct current, giving anything up to 100 amperes. He was quite sure that with correctly designed machines there would be no difficulty in running up to 5,000 volts, and with very large currents, up to several hundred amperes.

Mr. Nunn:—I suppose my testimony in reference to the alternating long distance plant that we have been operating would be apropos. I can say that from the first installation to the present time it has been under my care, and I consider it a brilliant success, especially when I compare it with direct current systems which are in use around us. Our greatest trouble has been from lightning and from grounds, principally the latter. The lightning has caused many defects and made many of the plants failures. It must he understood that we are in an unusual place. Our generating station was something over 10,000 feet high and our first motor installed was something over 12,000 feet high. We have made a run of 45 days without a discharging field of motor or generator. We have installed a 250 h. p. machine, and that is giving satisfaction so far. We do find a little trouble with some minor details, but they are purely a matter of the mechanical construction of the machines and not a part of the electrical connections at all. Ours are of the synchronous type. We have to start our motors with a special starting apparatus, and we once in a while have a little trouble with that; that is, as far as the operation of starting is concerned, it is very simple. The men who take care of these machines, with two exceptions, are men who never saw an electric apparatus before. I think I have had 16 different men in the last year and a half in attendance upon one motor, and without any exception these men have been able to take care of the motor without any trouble. I think this is a compliment, not so much to the sagacity of the men, who were simply western miners, but to the simplicity of the system. We have but two men at the generating station working 12 hour shifts, and they control the speed for our five miles and control it exactly, whether the motors are loaded fully or running light. The speed varies so little that it is one of the great beauties of our system. It must be understood that we use these motors in driving stamp mills in the reduction of gold ore and perfect speed is a paramount requirement. I do not think that the time can ever come that in the electrical field can be found a system more beautifully applicable to these cases of long distance transmission in which large units (when I speak of large units I mean over 50 h. p.) are required at a constant and uniform speed on 365 days in the year.

Mr. Henry Hine thought that long distance transmission was one thing; transmission of power for various purposes in a city was another thing. His company had been operating motors for some time successfully under their own supervision. **Dr. Kilbourne** thought it a good plan to put transformers in large banks instead of putting a transformer in every building. They had a bank of transformers and at night when the heavy load went off the night-watchman threw off the switches of two transformers, if there were three in the bank, and left one to carry the load for the balance of the night. **Prof. Forbes**, being called on, said he was very sorry but he hardly felt able just at the moment, to say much about the relative merits of the two systems. Of course he would have occasion to express his opinions on that subject pretty clearly in the course of the next week or two, and thought it would be hardly right for him to draw comparisons between the two at the present time. He could only say that both the three-phase and the two-phase system were working very satisfactorily in Europe. The only town in the world that he knew at the present moment where alternating currents are used for distributing power is at Heilbronn, Germany, but there might be others with which he was not acquainted; that too was on a very small scale. This only showed that the objections which were originally raised against the alternating current for use as motive power have not been completely annihilated up to the present time. He had seen at least a dozen kinds of single phase motors in the shops of various manufacturers.

The President then laid before the Convention an invitation from the Siegel Gas Fixture Company to visit their establishment; also an invitation from Mr. Henry Sylvester to inspect a model of a special type of underground sub-way. Also a communication from the Columbian Underground Electric Traction Company inviting the Convention to inspect a new street railway system, underground conduit. Also an invitation from the St. Louis Car Company to examine a new model president's car constructed by it for the New Orleans street railway system and costing about $9,000. The Convention then adjourned until 10 A.M. Thursday.

THURSDAY, MARCH 2.—MORNING SESSION.

Mr. William J. Hammer, in response to the request of the president, read **Mr. W. H. Browne's** paper, entitled "Underground Conduits and Conductors, and the Experiences of the Electric Lighting Companies of New York City."[1]

The President: This question is peculiarly interesting to the companies in St. Louis, where the subject has been agitated in the last year or two. Efforts have been made to pass State laws compelling the companies to go underground in the cities of Missouri. The telephone company here has been endeavoring to get underground—endeavoring to get a franchise to go underground, but there is a difference between them and our local legislators, and they seem to be unable to get a satisfactory franchise. At the same time the local city government have been endeavoring to procure State legislation compelling them to go underground. No doubt many of you have had similar experiences.

Mr. De Camp stated as the result of his underground experience in Philadelphia that lights on the underground mains cost him 10 or 15 cents a night more than did those on the overhead circuits, and of course he had to charge more. There was no help for it. He understood, moreover, that the whole underground construction in New York to-day would not pay one per cent. on the investment in it. If anything, he favored the city building and owning subways, so that people might at least know what the heavy expense of subways was.

Mr. M. J. Francisco—There is no question in regard to the feasibility of placing these wires underground. That has been fully demonstrated. It is simply a question of commercial success. But at the present time it is almost impossible for a company in a place of 300,000 or 350,000 inhabitants to operate an underground circuit and pay expenses. As a general thing the cost of constructing the conduit would average about $4,500 per mile of one duct only. His view of this thing was that the city should construct the conduit and furnish it to the electric light companies at a reasonable rental. He recommended that the electric light companies, in states where conduits are to be used, should take such measures as would procure an enactment by the legislatures of those states of certain laws regulating the rental of conduits, so that there shall be a fixed rental made by the legislature of the state. Then they would know where they stood. The city should construct the conduit and rent it at that price, otherwise in small places it is utterly impossible to run or operate in a conduit.

Mr. J. J. Moore, of New York, went into a story of the manner in which lighting had been contracted for in New York, and in which prices had been raised owing to the introduction of the conduits which were more satisfactory than overhead wires, but it was only the commercial lighting that saved the local companies. He did not favor the building of conduits by cities. If they built them, it would only be the next step to pull wires in for themselves, and then it would be a "municipal plant." The local company should protect itself by owning the conduits it was using.

At this stage the discussion took a turn that led on to the competition and cutting of rates, whereupon the President announced the next paper on "The Incandescent Lamp from a Commercial Standpoint[4]" by Calvert Townley.

The paper was read and the meeting was then adjourned until 2 p. m.

THURSDAY AFTERNOON SESSION.

Vice-President Armstrong called the meeting to order. The first business was the reading of the paper of Mr. H. C. Meyers on "The Vulcanizing Process for the Preservation and Strengthening of Poles, Cross Arms, Ties,[2] etc."

The paper of Mr. E. A. Armstrong, on the "Morals of Corporations,"[3] was read as follows:—

The discussion on the paper of Mr. Calvert Townley, on "The Incandescent Lamp from a Commercial Standpoint,"[4] which was read at the morning session, and discussion on which was postponed until the afternoon session, was then taken up.

A rather general discussion was participated in on the relations of the supply companies to central station men which was incidentally introduced.

---

[1] See page 241. [2] See page 233. [3] See page 231. [4] See page 237.

Mr. Edward Weston gave a most interesting description of the successive stages through which the incandescent lamp has passed, as regards the production of the carbon and guarding against the rapid destruction of the lamp.

The discussion concerning the local companies and the lamp policy of the General Electric Company was participated in by Dr. Bell, A. J. DeCamp, T. C. Smith, J. J. Burleigh, and W. S. Howell. It was very acrimonious and needlessly personal and was virtually expunged from the record.

The question was referred to the Committee on Relation between Manufacturing and Central Station Companies.

Mr. Armstrong offered the following resolution:

Resolved—That the sincere thanks of this Association are due and are hereby tendered to the Citizens of St. Louis, the Electric Club, the Electrical Exchange, the Bell Telephone Company and the city press for the very full reports, as well as to many others, for the very elaborate courtesies they have extended to us, which have rendered our stay here so exceedingly pleasant. We have discovered that the kind proffer of His Honor, the Mayor, in his welcoming address, has been liberally realized:—"St. Louis and all that she has is ours."

The resolution was unanimously adopted.

Mr. Armstrong offered the following resolution:

Resolved—That we extend as an Association and individually our thanks to our esteemed President James I. Ayer, for the ability and courtesy with which he has discharged the responsible official duties of his position. As individuals we want to put on record the fact that from our experience here in St. Louis at this convention, we have learned that his affability is perfectly generated; it is of the highest efficiency, the lines are innumerable and are all overground; the current is sent out without a drop or flash, and on these lines there is no switchboard, throw out, cut-off or arrester; and against its power no amount of trouble has been able to act as an insulator.

The resolution was unanimously adopted.

President Ayer responded to the resolution and expressed himself as pleased to know that the delegates had been so well provided for; and said that he, in turn, was indebted to the citizens of St. Louis for the earnest efforts they had put forth on this occasion.

He thanked the gentlemen for the attention they had given to the meetings of the Association.

At this point the regular sessions closed; and the meeting went into executive session.

An interesting feature at this time was the passage through Tenth street of the vehicles used in the service of the Municipal Electric Light and Power Company of Mo., of which Mr. Ayer is general manager. The procession consisted of the superintendent's light wagon, pole wagon, dynamo wagons for the handling of heavy machinery, linemen's wagons, trimmers' carts, inspectors' carts, line repairers' carts, metermens' carts, and one or two other kinds of carts; the whole aggregating about eighty. The company serves a territory of upwards of sixty square miles in St. Louis, and finds these vehicles necessary in the conduct of its business.

In the executive session the Secretary's report was read, which showed the Association to be in a most healthy financial condition.

There were 31 new active members gained during the year; and the total membership of all classes is now 250.

Nikola Tesla and James I. Ayer were elected as honorary members of the Association.

A hearty invitation was given to the Association by Dr. E. C. Kilbourne, of Seattle, Wash., for the Association to meet there next year. The invitation was most cordial, and went to the extent to state that the expenses of every one in attendance at the meeting would be paid by the citizens of Seattle.

The following were then elected the officers of the Association for the ensuing year:

President, E. A. Armstrong, Camden, N. J.
First Vice-President, M. J. Francisco, Rutland, Vt.
Second Vice-President, C H. Wilmerding, Chicago, Ill.
Secretary, George F. Porter, New York.
New members of the Executive Committee: J. A. Seely, New York; E. F. Peck, Brooklyn; A. J. DeCamp, Philadelphia; W. A. Morrison, Woodstock, Conn.; H. J. Smith, New York; G. H. Blaxter, Pittsburgh.

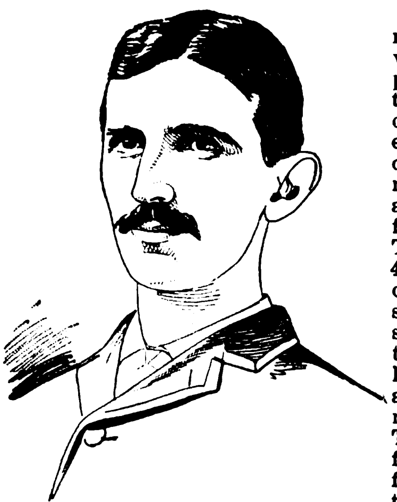
The place for holding the next meeting was referred to the Executive Committee.

The convention then adjourned.

DONALDSON-MACRAE ELECTRIC CO.

It was at Baltimore that the first Faure storage battery which arrived in this country was landed, and that city has ever since been the scene of activity in this field. Among those who have more recently devoted attention to storage battery work are the Donaldson-Macrae Electric Co., of No. 215 N. Calvert St., Baltimore, whose batteries have been put to use for a variety of light and power purposes, and some of whose installations have already been described in the Engineer. The active material in the Donaldson-Macrae cells is entirely enclosed by a perforated lead pocket so that under no conditions can it become loose and fall away from the plates. We may add that the company is operating under license from the Consolidated Electric Storage Company, of New York.

THE TESLA LECTURE IN ST. LOUIS.



Nikola Tesla.

The Tesla lecture was a notable feature of the convention. At first it had been proposed to deliver the lecture in a small hall, but the demand for tickets was so enormous that it was decided, as a matter of sheer necessity, to secure a larger auditorium, and this was found in the Exhibition Theatre, which seats about 4,000 people. It was, of course, practically impossible that all could hear and see, but those who were there could at least say they had seen Mr. Tesla afar off and witnessed some of his most striking experiments. The hall was crowded to suffocation. and the demand for tickets was so great that they were selling briskly for three and five dollars on the steps of the hall. Under such circumstances Mr. Tesla contented himself wisely with showing some of the more "spectacular" of his experiments, and even these were followed at a disadvantage in view of the immense distance from which most of the spectators studied them. After his introduction by Mr. Ayer, the lecturer gave a few minutes to a statement of the conditions involved in his work, and then by means of his high frequency and high voltage currents, aided by disruptive discharge from a condenser through an induction coil—as well as by direct dynamic phenomena, he produced a number of the interesting results that have already made his name famous and have charmed two worlds. He received, unhurt, currents of hundreds of thousands of volts, lit-up tubes and lamps through his body, rendered insulated wires several feet long entirely luminous, showed a motor running under the influence of these million-frequency currents, obtained a number of effects with phosphorescent lamps; and also showed how little in such work the high resistance of the filament had to do with the lighting up of ordinary 50 or 110 volt lamps. His ability to produce such effects, either with a single wire and no return, or without any wires at all, aroused the utmost interest and enthusiasm and the concluding demonstration literally brought down the house, when he showed how by simply carrying lamps or tubes into a room or hall where those currents were being developed, illumination was the immediate result.

In his opening remarks Mr. Tesla enlarged upon the grandeur of Nature, and expressed his opinion that the most wonderful of the external influences that affect us is light. Hence it followed that the most wonderful and important of the organs by which these external influences beat in upon us is the eye. Two facts were specially referred to, one of them being that the eye is the only organ capable of being affected directly by the vibrations of the ether. Another fact was that the eye would be able to distinguish objects at almost any distance, were it not for the minute particles and stray gases filling the intervening space. These absorb the energies of the ether vibrations, but in a pure medium they would travel unchecked, and the range of vision would be infinitely greater. Mr. Tesla then alluded to the importance of the part played by the eye in furnishing the race with its ideas and knowledge, and to its vital function in controlling all our motions and actions. From its teaching were derived consciousness, ideas, conceptions that were impossible without images—and images involved sight.

By these interesting stages, Mr. Tesla led up to the subject of light and thence to the part of electricity in giving us light. The general aim of the discourse was to show and explain the phenomena due to electrostatic forces, followed by phenomena produced by electro-dynamic agencies; and, then, as a third class, the light effects, Mr. Tesla's idea evidently being to give a generalization of these phenomena, and of their relations. It was stated, parenthetically, with regard to the physiological effects produced with the high tension, high frequency currents employed, that a great amount of energy may be sent into the body of a person by their means, merely because the energy was dissipated laterally from the body and was not passed through the body in the direct manner involved in the use of a low frequency current. It was due to this intense rapidity of vibration that the lecturer was able to receive with impunity currents of as high as 250,000 and 300,000 volts, and of an amount which otherwise administered would kill. The lecturer explained that he had so arranged his apparatus that in case of any failure of any part of it, the current would kindly abstain from killing him, and would only knock him down.

Many of the experiments shown have already been seen either in this country or in Europe, yet there were several novel effects introduced, and even the familiar experiments were performed with apparatus different from that used before. In most of the experiments the ordinary alternating and continuous currents from the central station were used, although Mr. Tesla also had his own special generator running in the basement.

A striking new experiment was to show at the beginning of the lecture, the effect of a varying electrostatic stress through the dielectric. This experiment was performed by grasping one terminal of the high tension transformer giving about 200,000 volts pressure, and approaching the other hand, to the opposite terminal. Streams of violet light then issued from the fingers and the whole hand. (At the lecture on the preceding Friday at the Franklin Institute in Philadelphia, Prof. Houston noticed these streams of light coming also from the lecturer's back, following roughly the line of the vertebral column).

Another experiment was performed showing the action of the air between two condenser plates. By attaching these plates to the high-tension transformer, the whole space between these plates was filled with light, the distance apart being about ten inches. It was pointed out that these streamers consumed considerable energy and developed abundantly ozone and nitrous acid, and it followed that it was necessary to exclude air from high-tension apparatus.

The action of the air was shown in another very striking experiment. Two incandescent lamps exactly alike, one exhausted, the other not, both of the ordinary 50 volt type, were attached in multiple arc, and a current vibrating about one million times a second or thereabouts was passed through the filament. It was demonstrated that the lamp which was exhausted glowed brightly, whereas the other one in which the filament was surrounded by air, at ordinary pressure, did not glow. Yet the latter lamp got hotter than the other. This showed the great importance of the rarefied gas in the heating of a conductor, and it was pointed out that in incandescent lighting a high resistance filament does not at all constitute the really essential element of illumination, along these lines. Also that heavy blocks of metal may be brought to incandescence by minute currents provided they are surrounded by rarefied gas, and provided the potential and frequency of the currents is sufficiently high.

One of the most interesting experiments was the conversion on open circuit. A transformer was taken and the current passed through the high tension winding in such a way that only one terminal was attached to the source of the rapidly alternating current. In spite of this there was a current passing through the primary as though the other terminal was actually attached to the source like an ordinary return circuit. This open circuit transformer contained a secondary low tension winding, and the minute currents passing through the primary were transformed into currents capable of following the ordinary electric wire and lighting up brilliantly an ordinary lamp. It was pointed out that under certain conditions, indeed, such a conversion was quite practicable and that it can be practised with high economy. It was further pointed out that any kind of device such as motors, etc., may be operated in this manner, with one wire or circuit only.

Mr. Tesla in the course of his lecture dwelt upon his method of conversion by means of disruptive discharges from continuous or alternating station supply. There were two kinds of apparatus on the stage, one operated from the alternating circuit and the other from the regular direct current system. A peculiar form of discharger was used contained in a mica-lined wooden box. The spark-gap was warmed by a small lamp underneath, for the purpose of making the air dielectrically weak. This enabled Mr. Tesla to work with a very long gap, a very sensitive arc, and a comparatively small electromotive force in the gap. The effects obtained were thus augmented very materially. It was pointed out that with this method of conversion, there is no difficulty whatever in obtaining sparks of any length. It becomes simply a question of the energy supplied, through what distance the spark will be visible. During the lecture, lamps were operated by this method of conversion. An ordinary 100-volt, a 50-volt and a two-volt lamp were brought up to full candle-power with equal facility. Then a little motor was run by means of these disruptive discharges, it being a phase-motor comprising simply an iron core with a closed secondary coil in it, and a disc armature arranged to rotate above the core. Mr. Tesla remarked rather naively that if the demonstration were not quite equal to the expectation, the long continued and weary work on the development of the invention, besides the inability of the experimenter, might be the cause. He went on, in connection with this, to refer to the transmission of power from Niagara and gracefully recognized the presence on the platform of Prof. George Forbes, who is so prominently identified with this great work. Mr. Tesla believed that we were about to see such great powers transmitted long distances, and over one wire.

Continuing, Mr. Tesla remarked that he had shown things of a more spectacular nature with reluctance, yet forced thereto by the desire to gratify those who had shown their interest and formed so large an audience. A number of experiments were performed not seen in this country before, though some had been shown in England. For instance, a phosphorescent bulb was lighted up by being merely held in the hand, and this was a most successful experiment. Mr. Tesla prefaced it by relating a little anecdote of Lord Rayleigh. When he was in London, remarked Mr. Tesla, with much feeling, he had the pleasure of performing this experiment privately before Lord Rayleigh, and he would always remember the trembling eagerness and excitement with which that distinguished scientist witnessed the lamp light up. The appreciation of such men, said Mr. Tesla, repaid him fully for the pains he had been at in working out these phenomena.

In this experiment a number of tubes were taken and flourished or flashed in various ways, and with the current made intermittent at longer intervals by adjusting the spark-gap. Wonderfully beautiful effects were thus produced, the light of the whirled tube being made to look like the white spokes of a wheel of glowing moonbeams. Then some rectangular tubes were taken and flashed or whirled so as to produce curious designs of luminous lines.

A bulb was shown by Mr. Tesla said by him to be so highly exhausted that when the bulb was merely attached to one terminal of the disruptive discharge coil, it would send the sparks across the outside of the globe to the other terminal, which was on the opposite end, rather than pass through the bulb. The bulb in question was painted on one side with a phosphorescent powder, or mixture, and threw a most dazzling light, far beyond that yielded by any ordinary phosphorescence. It was pointed out that there was no difficulty whatever in obtaining powerful phosphorescent effect in this way, and that a practical illuminant on these lines needed merely the perfection of the method of conversion above alluded to.

In conclusion the lecturer made fine cotton-covered wires stretched on a frame over the table luminous so that in the dark they looked like attenuated violet caterpillars yards long; and then within a large rectangle formed by such wires he flourished tubes in the interspace, these tubes flashing with light wherever waved.

After the lecture, so great was the desire of the public to see Mr. Tesla closer, an informal reception was held in the lobby when several hundreds of the leading citizens seized the opportunity and Mr. Tesla's hand in a very vigorous manner.

It should be added that the Electrical Exchange, of St. Louis, presented Mr. Tesla at the beginning of the lecture with a magnificent floral shield, wrought in white carnations with a border of palms and American Beauty roses. It was about four feet in diameter. In the centre was a circle of red carnations bordering a tablet of white ones, beaing the letters in red $C = \frac{E}{R}$.

Around the circumference were the floral letters: "St. Louis Electrical Exchange 1893."

THE CONNECTING LINK BETWEEN CHICAGO AND DETROIT.

On Saturday Evening, February 18th, occurred the successful opening of the Chicago-Detroit Long Distance Telephone line. The event was celebrated at Detroit with a great deal of enthusiasm, as it was the first introduction of that city to the long distance telephone. The mayor and all the city officials and a large number of prominent citizens were in attendance. At the Chicago end of the line were F. A. Baker, representing his brother, Wendell Baker, contracting agent of the long distance company; D. Richardson, and Special Agent Fuller, of the Bell Company; De Wolf Hopper, and F. L. Grannis, the banjoist, and a number of newspaper men. It was 6 o'clock when the line was opened and the Detroiters sent the first greeting over the wire to Chicago. The line was in excellent order and every word could be heard distinctly.

The line is the same in its construction as that between Chicago and New York. At Detroit communication was opened with New York, Pittsburg, and other cities east at the same time the Chicago line was opened. Mayor Pingree of Detroit, talked with Mayor Gilroy of New York, while Ex-Governor Alger had a conversation with Ex-Senator Warner Miller at the Fifth Avenue Hotel in New York. In addition to music from Chicago, the Detroiters heard in turn a cornet solo at New York and a recitation at Pittsburgh. The arrangements at the Detroit end were in charge of Wendell Baker, contracting agent, and Mr. Stoughton Walker, district superintendent of the Western division, including all the lines west of Pittsburgh.

UNION OF GERMAN ELECTRICAL ENGINEERS.

A call has been issued by a number of prominent German electrical engineers for the founding of a society to be known as the "Verband der Elektrotechniker Deutschlands." The object of the society is to promote friendly intercourse among members of the electrical profession, the cultivation of scientific and national interests in electrotechnics, and the creation of a body, which shall have the power and be in a position to express and represent effectively the consensus of electrical opinion in Germany. A considerable number of members have already joined the society.

EXHIBIT NOTES.

The Electric Selector and Signal Company.—All the central station men flocked to parlor 54, where something that was new to many of them was shown in full operation. This was the very well-worked out system of individual cut-outs of the Electric Selector and Signal Company (formerly the Electric Secret Service Company), of New York. The room where these devices were shown at work had the appearance of a small central station. In one corner was a C. & C. motor, supplied from one of the street circuits, driving a similar machine as a dynamo. This generator supplied current for a new form of Lundell motor and for the lamps and motors used for showing the operation of the selective switches. A number of these were arranged on a single circuit and each controlled a loop containing a "translating device" in the form either of a group of incandescent lamps or a Lundell fan motor. The central station transmitter governing the selector was placed near the generator to correspond with the position it takes in practice in the central station. The transmitter is a simple clockwork movement driving a disc for operating the circuit breaker. On the discs are cut the combinations corresponding to the selectors. A single depression of the key of the transmitter drives the disc a complete revolution, working out the combination of makes and breaks on the circuit breaker. Each selector has a separate and distinct combination to which alone it responds, and although the current passes through all on the line only the desired one operates its automatic switch, cutting the loop which it controls in or out of circuit. The switch alternately makes and breaks so that the operation of closing is the same as that for opening the circuit. The operativeness of the system was completely demonstrated and the exhibit shown was sufficiently extensive to make clear its applicability to the control of circuits of all kinds at points distant from the central station. Every central station manager who inspected the working of the system was impressed with the advantages it contained in placing the control of all circuits where it belongs, *i. e.*, at the generating plant or centre of distribution. The principle of individual selection has many other applications in different branches of electrical work, such as telegraphy and block signalling, and the Electric Selector and Signal Company has already done some very successful work of this kind for different railway companies. We see a large field of usefulness for this system. Those who are interested in making a more exhaustive inspection than was possible at the Convention can see a very complete installation of the various devices at the Company's headquarters, at 45 Broadway, New York.

The Weston Electrical Instrument Co., of Newark, made a really magnificent exhibit under the care of Prof. R. O. Heinrichs and Mr. C. D. Shain, while all the delegates were delighted that Mr. Edward Weston was present as a guest of the Association and to be able to discuss with him the principles upon which his beautiful instruments are based. Encouraged by the warm appreciation that has greeted his portable instruments of the permanent magnet type, Mr. Weston has now taken a most important step and has devised some of the best and finest central station voltmeters and ammeters, of the same type, that this country has ever seen. Some of these instruments were shown in circuit. With them were also shown the ingenious shunts used with the ammeters, and the leads that go with the apparatus; so that any central station man could realize correctly just how he could apply such instruments in his own station. There was also shown in the Weston parlor a superb direct reading laboratory voltmeter as well as an interesting and fascinating board on which were mounted separately all the details that are used in the Weston instruments. It was indeed a showing of fine workmanship, choice materials, and subtle adjustment of parts to purpose, that any inventor might well be proud of. Mr. Weston's high standing will certainly not suffer from such a display as his company made in St. Louis. It should be added, that, in order to meet the demand that comes to them, they have also made, and showed, a line of electromagnetic instruments in which the variability to which such instruments are liable has been reduced to the smallest minimum, so that they are practically free from variation.

The Goodrich Hard Rubber Co., of Akron, O., were well represented by Mr. J. C. Pierrez, who made it a personal duty to "round up" with every man in the Convention in anyway likely to be interested in such articles as the concern produces. Hard Rubber in an endless variety of forms has come to be a necessity of most of the modern work in electricity. In fact without it, many of the applications would be well-nigh hopeless. The Goodrich Company were early in appreciating this fact, and their goods, both by variety and excellence, have come to hold a most enviable, yet entirely deserved reputation and position in the trade and art. Mr. Pierrez did not deem it necessary to make an exhibit or to load up the delegates with samples. "Wherever you go in electrical St. Louis, you will find our product," he said.

Mr. D. Spruance represented the new Helios arc lamp for alternating circuits. It was shown in various places and gave a beautiful steady light, while its low voltage, simplicity and general availability found it many admirers. The Helios lamp seems destined for wide use.

The Electric Engineering and Supply Co., of Syracuse, had an exhibit of some of their handsome specialties in parlor 74. Among them was their handsomely mounted concealed terminal station switch which has no superior in style, mechanical construction or finish, and received unqualified praise and approval by all electricians and laymen. Another piece was their flush switch for the conduit system of wiring. It is claimed to be by far the handsomest switch of its kind and evokes universal praise. They also showed a porcelain-covered branch block, which, by means of a porcelain cover has all the brass parts perfectly covered, and is approved by the board of fire underwriters; also a few samples of their E. E. & S. sockets which are so well known on account of their peculiar and desirable quality of porcelain insulation and their unusual capacity for heavy currents. There was also shown a new fusible wall socket which is a combination of socket and fusible rosette; also a complete line of incandescent snap switches. This company are making a large number of incandescent switchboards, and arc plug boards, of which they showed photographs and designs. They are making these boards in any desired style and plans and prices. Mr. Goercke was in charge of the exhibit.

The Boston Incandescent Lamp Co., of Boston, Mass., had an attractive and interesting exhibit of their new series lamp, to be used on arc circuits. This is an important field of work that has been greatly neglected. The manufacturers of this lamp have had considerable experience at the Thomson-Houston factories, and are now producing a perfected series lamp at a very moderate cost. Central station managers desirous of increasing the carrying capacity of their series arc circuits, should write at once for prices and descriptive catalogue. The exhibit was in charge of Mr. Matt Merritt, of the company.

Mr. Chas. D. Jenney, of the Jenney Electric Motor Company, was here, there, and everywhere, like his motors, in the interests of his company. The company were without an exhibit at the Convention, but this was hardly necessary, however, for the position of popularity held by Jenney apparatus is now world-wide. Mr. Jenney is one of the youngest and yet one of the oldest in the electrical manufacturing business. The Jenney Electric Motor Co., of which Mr. Jenney is the head, is among the most prominent and have one of the most completely equipped factories in the country.

The Eddy Electric Mfg. Co. were well represented by Messrs. Newton and Baird and had a fine display in one of the large vacant stores in the hotel. It included their new type of motor, and of these two were shown, one being 15 h. p. and the other 1 h. p. These machines are characterized by all the simplicity, strength, and high finish which, combined with other qualities, have done so much to place Eddy motors and generators in the front rank. The company also had on the ground, the brothers G. E. Kohler and Frank Kohler, who are so successful in the Chicago agency.

Mr. E. V. Matlack, of the Laclede Power Company, of St. Louis, had an interesting exhibit of C. & C. motor and generator furnishing current for the exhibit of the Electric Selector & Signal Company. He is running a large 500-volt power plant in St. Louis, with C. & C. generators and motors, carrying as much as 30 h. p. in one lump three miles from the station. The plant used at the hotel for the exhibit is to be set up in the new telephone exchange to charge storage batteries for ringing.

The New York Insulated Wire Company were represented by Messrs. J. W. Godfrey, from New York and the boundless West, and Mr. E. Ruebel, of St. Louis. The latter gentleman rather had the advantage of the former by distributing neat little souvenir pocket books containing a choice Godfrey portrait adorned with prize Dutch skate moustaches. The picture is taken full tone, as it was found that half tone was not equal to the work.

The Cutter Electrical & Mfg. Co. had an interesting exhibit of specialties in their parlors, including flush switches, push button switches, etc. Their "flexible bracket" is too well and favorably known to need mention. Their new commutation switch is worthy of a careful examination. This switch admits of the operation of any number of lamps from any number of stations. An example of its working is the operation by one switch of the lights in six different rooms of a residence. Mr. H. B. Cutter was personally in charge.

The Mosher Electric Co., of Chicago, whose arc lamps for direct and alternating arc circuits were illustrated and described in the last issue of the Engineer, were shown in the hall of the Electric Club, in the Equitable Building, under the aupices of the Western Electrical Supply Co. of St. Louis, who also showed them at their offices.

"Tommy" Grier and his Chinamen were on duty during business hours extolling the merits of the Bryant Specialties, for which he is Western agent. "Tom" is well-known, well-liked, and is doing an excellent trade. A desirable line of goods is carried and their storerooms are always fully stocked.

Norwich Insulated Wire Company.—The above-named company was represented on the Electrical Special and at St. Louis by its treasurer, Mr. George J. Jackson. Mr. Jackson had the pleasure of showing many of the delegates and visitors his case of samples of fine cables—paper insulation and lead covered—ranging in size from No. 20 house wire to one of 2,000,000 circular mils for station and conduit service. These wires are water and fire proof. One of the interesting novelties shown by Mr. Jackson was a corrugated lead covering, the corrugation facilitating the drawing-in process in conduits. The ribs were $\frac{3}{32}$ inch deep and $\frac{1}{8}$ inch apart. Another novelty was a concentric double cable, the inner conductor being a No. 4 copper wire and the outer one being a cylinder made up of a ribbon of copper—the conductivity of the cylinder being equal to that of the inner wire. This cable has many obvious advantages over the ordinary two wire cable and in view of its superior insulation and compactness, will doubtless enjoy a wide sale. The offices of the Norwich Insulated Wire Company are at 44 Broad street, and their factory at Harrison, N. J.

Westinghouse Electric Mfg. Co.—Messrs. Calvert Townley, L. B. Stillwell, A. J. Wurts and E. H. Heinrichs, of Pittsburgh, Mr. C. E. Bragg, of Philadelphia, Mr. C. W. Stewart, of Chicago, and Mr. E. W. Seymour, of New York, were at the convention in the interests of the Westinghouse Electric & Mfg. Co. Mr. Heinrichs distributed a very interesting stopper lamp folder, and filled the local papers full of "three star" Westinghouse oratory.

The C. W. Hunt Co.'s illustrated catalogue distributed at the convention was very interesting to many showing as it did views of the almost unlimited classes of work turned out by this well known concern. This company make nothing but the highest class of machinery from the very best materials.

Mr Walter C. McKinlock renewed acquaintance with his many St. Louis friends. Mr. McKinlock is now President of a successful Supply Co., (The Enterprise Electric Co.) in Chicago, maintaining as well a St. Louis branch, with Mr. Ferris as manager. N. I. R. Seamless Rubber Insulated Wire was a general topic of conversation.

The Fibrone Terraloid Co, of Newark, N. J., had an exhibit of their many specialties for use in the manufacture of lamps sockets, etc. A handsome paper weight of their peculiar compound was eagerly sought for, but somehow very few got around.

Ernest and John—poles and ties—otherwise explained means the Valentine Clark Company. They were there doing their utmost in the interest of their company; in fact Ernest filled his pockets so full of orders that he was obliged to leave for home a day early to give them proper attention.

Schieren Belts.—A 72 inch perforated four ply leather belt made by the Chas. A. Schieren Co., of New York, attracted a great deal of attention. The New York office of this well-known company was represented by Mr. E. P. Atkinson. and the Chicago office by Mr. A. W. Harvey.

Jewell Belting Co.—A very handsome and "useful" souvenir was the pretty morocco paper currency folder presented by Mr. C. E. Newton and Mr. Wheelock, who were on the ground in the interest of the Jewell Belting Co. of Hartford, Conn.

J. R. Coffman is now posing under a new cognomen that of "Eureka." He showed a handsome line of Street Car Motor and Generator Segments for all systems, also segments and brushes for all systems of lighting machines, both arc and incandescent.

President J. W. Wilshire of the Card Electric Motor and Dynamo Co. spent a couple of days at the Convention in the interests of his company, which is now in better shape than ever to handle the large and solid motor business which it has built up.

Carpenter Rheostats.—The popularity of the Carpenter Enamel specialties is undeniable. Many who were unable to see Mr. Carpenter before leaving were heard asking, "Has Carpenter gone?" When told that he had gone and his exhibit with him, they were very much disappointed.

Mr. P. C. Burns, of The Laclede Carbon & Electric Company, will shortly make his headquarters at Chicago. He is likely soon, being an old telephone man, to make a profitable straddle between electric lighting and telephony.

President Henry C. Adams, of the Phillips Insulated Wire Co., was there in the interests of his Company. A countenance beaming with pleasure at all times, suggested interviews of material benefit to his company.

Ned Fox, of the Phœnix Glass Company, of New York, did not arrive at the scene of action until Friday morning. A great many visitors had left but those still around were glad to greet him.

The Heisler Electric Co. needed no introduction to St. Louis, where it was once emphatically a pioneer. It was represented by Messrs. Walter F. Smith and W. S. Horry, who are now building some very fine large alternators and pushing into an entirely new field of work.

Novel Advertising.—Among the many novel advertising schemes resorted to, the Electric Appliance Company will have to be given the first prize for originality. In addition to numerous circulars of their specialties and a small pamphlet of testimonials entitled "What others Think," which was attractive enough to deserve special mention, they kept their friends supplied with first-class cigars bearing the "Paranite" label, which is a sufficient guarantee that they were the best to be had. The great strike however was their quill toothpick bearing the legend: "Electric Appliance Company, Electrical Supplies, Paranite Wire, Chicago." The dining room of the Southern Hotel was supplied with these during convention week and each guest at the Friday banquet at the Jockey Club secured a package. The toothpicks were made of celluloid in assorted colors in the form of quills; and tied up in packages of ten or a dozen, the bright colors gave a very pretty effect. It was certainly a very original advertising scheme.

Mr. Thos. I. Stacey, treasurer and manager of the Electric Appliance Company made his first bow to an electric light convention. All enjoyed his "Paranite" cigars and were glad in consequence to make frequent calls on Mr. S. A very interesting grip full of their well-known specialties was taken down to the convention. This fact, the cigars, etc., made him at all times the recipient of plenty of calls. He returns home a thorough conventionalist and we think from his very pleased air that the inner vest pocket must have contained some handsome orders for "Paranite," Elkhart Transformers, etc., etc.

Standard Electric Co.—The excellent system of arc lighting manufactured by the Standard Electric Co. of Chicago has made a most flattering "entree" for isolated work in St. Louis, some handsome contracts having recently been secured. Mr. D. P. Perry, president and Mr. F. E. Drake were on the ground and were kept busy extolling the merits of their dynamos and lamps. This company have most excellent facilities and manufacture everything necessary for the electrical equipment of an arc plant.

Mosher Electric Co.—The interests of the Mosher Electric Company were admirably taken care of in the hands of president G. L. Reimann, and Mr. Mosher inventor of the Mosher arc lamp. The alternating arc lamps were on exhibition at the store of The Western Electric Supply Company, and two of their direct current incandescent arc lamps were shown in the rooms of the St. Louis Electric Club.

Mr. Harry Wilson did excellent work holding down the western end of the C. & C. Motor Company's interests. Power was secured and one of these well-known motors was in running "order" at all times to interest the many callers at Mr. Wilson's parlors. Treasurer Hall of the C. & C. Company was also present and busy.

Mr. A. D. Adams had a manifold duty to perform. Besides contributing a most valuable and interesting paper, he had the interests of his company, The Commercial Electric Co. of Indianapolis, to look after. It is needless to say his duties were well taken care of.

Jas. J. Murray & Co., of Philadelphia, who have deservedly captured so large a portion of the glassware trade in the electric lighting field, were on hand to greet old customers and to secure new ones. They find a growing appreciation of their artistic products.

The American Electrical Works were represented at the convention by Mr. P. C. Ackerman. This is not strange however for a convention without P. C.'s familiar face would be a surprise. The Works are still making a very superior brand of playing cards.

Mr. A. M. Morse, resident manager of the Buckeye Engine Co., was a frequent caller at headquarters whenever it was possible to leave his handsome offices in the Commercial building; a roll of specifications usually accompanied him.

Diehl Motor Co.—There were many interested readers of the widely distributed circular of the Diehl Motor Co. These motors have a long record of meritorious work. They have been described in the columns of the **Engineer** already.

Mr. C. J. Butler, manager of the Indiana Rubber and Insulated Wire Company was a day late in showing up at the Convention, but he "was there." Butler and Stacey made a decidedly strong Paranite team.

The many Friends of Mr. Geo. Cutter regretted to hear of his, to be hoped only temporary, indisposition which necessitated his immediate return home.

R. B. C.—Of course all know that these initials in reality "stand for" Ward Arc Lamps. Mr. Corey took admirable care of the interests of the Electric Construction & Supply Co. of New York.

H. T. Paiste attended the convention entirely on his own behalf, and found so many admirers of his products that he may soon be tempted to bring out a new line of specialties.

Pentz-Reckenzaun Meter.—This meter, which was shown by Mr. J. A. Pentz, of Philadelphia, is a highly interesting and novel one. It works entirely by gravity. It has two bars, each controlled by its own magnet. These bars fall by their own weight. They are brought back into position by means of a make-and-break contact, which is produced by means of a shunt circuit, and requires but one-fortieth of an ampere to set the bars in motion. The front bar runs at a fixed speed; the back bar, which is a permanent magnet, is controlled by the current and is accelerated or retarded in proportion to the amount of current flowing through the meter. It is quiescent until the first lamp is turned on, and ceases to work immediately after the last lamp is turned off. The meter has a plain dial upon which are five ordinary reading discs, showing the stage of current consumption. The machine is purely mechanical, is simple and accurate, can be easily transported, and may practically be set up anywhere. These meters are now on the market and are made to be operated by either direct or alternating currents. This meter is due to the combined efforts of Messrs. Anthony Reckenzaun and James A. Pentz, and is handled by a company at 1001 Chestnut street, Philadelphia, Pa.

President W. H. McKinlock, Mr. C. E. Brown and Mr. H. H. Small were present in the interests of the Central Electric Company. This popular supply house maintains a very successful St. Louis branch, the officials of which together with the officers and others of the home house lost no opportunities to sound the praises of the true and tried "Okonite" and their many other specialties. Mr. Geo. T. Manson, of the home office of the Okonite Company, was present at the convention in the interests of his company.

Ansonia Electric Company, or the Electrical Supply Company as it has been known favorably for years, continued its custom of having a host of representatives at the convention. General manager F. S. Terry, Messrs. D. E. Goe, Chas. E. Wirt and N. W. Wood, representing the heads of at least four departments of this popular house, were in attendance at the convention. It is needless to say the interests of the Ansonia Electric Company were well looked after.

The Falls Rivet & Machine Company.—Mr. E. L. Babcock, president of the above named company, and his son Charles represented their celebrated clutches at the Convention and were unceasing in their efforts to make things pleasant for their friends and customers of whom many were in attendance. Mr. Babcock left St. Louis with the justifiable elation due to having secured four handsome contracts while in St. Louis. Mr. Babcock's factory is working night and day to keep up with orders.

General Incandescent Arc Lamp Company.—The exhibit of the General Incandescent Arc Lamp Company was certainly a most interesting and novel one. This company are making a specialty of highly ornamental arc lamps for indoor and outdoor lighting. Some very exquisite designs were shown. The workmanship on these goods is so near perfection as to practically baffle competition. Mr. Gus. Noll was personally in charge of the exhibit, which attracted universal attention.

The Interior Conduit and Insulation Co., of New York, were represented by E. W. Little and Romaine Mace. They had a neat exhibit of their Lundell generators and motors in the smaller sizes, running fans, etc., off the circuits of the Electric Selector & Signal Co. They also distributed a very fine edition of their Architects' Electrical Bulletin, which contained 12 pages of illustrated matter relative to Interior Conduit and questions of wiring.

Alexander, Barney & Chapin were admirably represented by Mr. H. G. Issertel. The anniversary of the incorporation of the company was celebrated by Mr. Issertel in a neat way on Wednesday. In the morning, the gentlemen were given boutonnieres and in the evening the ladies were given beautiful bouquets to be worn at the Tesla lecture. It is needless to say that this floral tribute to brains and beauty was highly appreciated.

Fort Wayne Electric Company.—The parlors of the Fort Wayne Electric Company were practically besieged with interested ones looking at the new direct current arc lamp for incandescent circuits. A handsome working arc lamp for alternating currents was also in operation, a double and single carbon both being shown. Messrs. Morrison, Wood, Knight and several others connected with the company entertained magnificently.

Mr. W. D. Packard, of the New York & Ohio Company, makers of the justly celebrated Packard lamps renewed acquaintances made not only at the conventions of which he is always an enthusiastic attendant but with those who have come to know him through using his excellent lamps. Mr. Packard is going in for electric railroading enterprises in his spare time, at Warren.

The Chas. E. Gregory Co. of Chicago, represented by their principal, had on exhibition their wire tightening ceiling board, their insulated hanger for arc lamps, and their "Acorn" weatherproof switch. These and other novelties made a very neat and effective display.

Mr. W. J. Hammer visited St. Louis for the purpose of enjoying a professional holiday, and enjoyed it. He was the recipient of a great many congratulations on his William Wallace articles appearing recently in The Electrical Engineer. The *Electric Spark* of Chicago, circulated during the Convention, paid him the compliment of referring especially to these articles and of reproducing in miniature one or two of the more interesting cuts.

Mr. George Cutter, of Chicago, made a very tasteful display of his electrical supplies, including not only such well-known specialties as the Pattee lamp hour recorders, Cutler instruments, Pass & Seymour's porcelain wares, but a large variety of fine sockets, switches. etc. With him were Messrs. F. McMaster and H. L. Hadaway.

The E. G. Bernard Co., of Troy, N. Y., were represented by Mr. E. G. Bernard who exhibited the Powers arc light cut-out made by his concern. It has already been illustrated in these columns. It is a strong, neat piece of mechanism, thoroughly insulated with porcelain, and made with glass or metal face. Mr. Bernard also showed their new special safety porcelain cleat.

Harry P. Bishop, Chicago, representative of the Massachusetts Chemical Company, lost no chances to sound the praises of "Insullac." Mr. Bishop spent several days in the *Muddysippi* city previous to the opening of the Convention, and as a result it will not be long before all the prominent supply companies will be well stocked with this already famous insulating compound.

The Standard Underground Cable Co. were represented by Mr. J. W. Marsh, vice-president and general manager, and their Western sales agent, "Fred" E. Degenhardt, the only exhibit being in Mr. Degenhardt's words, "our natural propinsities." These are of course so well-known that it is unnecessary to enlarge on them.

The interests of the "oldest" electric supply house in New York were taken care of by Mr. Frank A. Magee. In short an Electric Light Convention without Frank Magee would be incomplete, and the affairs of The E. S. Greeley & Co. were safe in his hands.

Mr. Chas. E. Gregory, of the Chas. E. Gregory Company, who has secured the very desirable factory recently occupied by The Forée Bain Electric Company, in Chicago, was on hand. A circular descriptive of a most interesting line of specialties, more particularly in the interest of Central Station people, was distributed. Mr. Gregory's business is peculiarly one of his own as he maintains besides the above, a first-class exchange for everything electrical.

A very handsome exhibit was that of a 2 h. p. alternating motor, manufactured by the Wagner Electric Mfg. Co. This machine was located in the private office of the Missouri Electric Light Co., where it was viewed by many interested people.

Mather Electric Company.—Be it observed that the interests of the Mather Electric Company suffered not in the hands of Charlie Hill, and nearly every person was the recipient of one of the little souvenir screwdrivers. They made a hit.

Several Electrical Engineers of standing were present at the Convention, including Fremont Wilson, John A. Seely, F. W. Royce, A. H. Bauer (electrician Pullman Co.), and others.

A Pretty Little Souvenir of the Convention was that distributed by Mr. E. G. Bernard—a tasteful and costly card case, with four pockets, and bearing a gold inscription that signified its origin.

Mr. F. P. Little arrived in time to represent Chicago as well as Buffalo. The operations of his new company are becoming very extensive.

The General Electric Company were without exhibit, except the Convention itself, and were represented by Dr. Louis Bell, Mr. B. E. Sunny and Mr. J. J. Moore.

The Western Electric Company were represented by Col. G. L. Beetle and E. W. Goldsmith.

The Kester-Atwood Electric Co. of Chicago were represented by Mr. J. F. Kester. This company are putting on the market a desirable arc lamp for incandescent circuits.

Mr. Geo. C. Bailey, and Mr. A. B. Conover, General Sales Agent, for the West, had the interests of The John A. Roebling's Sons Co. in charge. A little bird whispered late Thursday p. m. that some nice business had been corralled.

The Standard Paint Company, makers of the famous P. & B. insulating compounds, were represented by their Western Manager, Mr. P. H. Hover.

The Madison Car Co.'s agent, Mr. Spencer Munson, was in St. Louis, and while not directly interested in the electric light business renewed many acquaintances around the Southern Hotel.

Taylor, Goodhue & Ames were represented by Mr. Wells Goodhue. A very handsome model of their Diamond transformer attracted a great deal of interest.

LIST OF ATTENDANTS AT THE ST. LOUIS CONVENTION.

Allegheny, Pa.—D. Hunter, Jr.

Altoona, Pa—W. H. Markland, E. B. Greene.

Anniston, Ala.—Howard W. Sexton.

Baltimore, Md.—H. C. Tudor.

Battle Creek, Mich.—J. B. Foote.

Beardstown, Ill.—W. E. McCullough.

Birmingham, Conn. Robert E. Wyant.

Boston, Mass.—Dr. Louis Bell, C. S. Haley, Chas. I. Hills, Geo. F. Talcott, H. H. Brooks, Capt. William Brophy, Benjamin Taft, J. H. Mason, Robert B. Tabor, Matt M. Merrit, Charles E. Bibber, Addison G. Sargent, D. F. Urquhart, W. S. Key.

Bridgeport, Conn.—W. C. Bryant, C. E. Carpenter.

Brooklyn, N. Y.—T. E. Crossman, James Ferguson, Frank C. Mason, E. F. Peck.

Buffalo, N. Y.—R. J. Getz, William C. Hodge, F. P. Little.

Camden, N. J.—Hon. E. A. Armstrong, Miss Elizabeth W. Armstrong, Miss Carrie W. Morgan, John J. Burleigh, Mrs. John J. Burleigh, Miss Retta Burleigh.

Canon City, Col.—H. B. Slater.

Carthage, Mo.—S. E. Whitehead, H. H. Harding

Carterville, Ill—F. C. Zimmerman.

Chanute, Kas.—William J. Bailey.

Chicago.—Geo. C. Bailey, W. D. Ball, Col. Geo. L. Beetle, C. E. Brown, M. J. Bulkley, E. W. Buss, Paul D. Cable, John R. Coffman, A. B. Conover, J. F. Conner, L. W. Collins, W. F. Collins, E. A Cummings, Geo. Cutter, F. R. Degenhardt, Fred DeLand, J. W Dickerson, F. E. Drake, S A. Douglas, Miss Annie E. Fortiner, E. W. Goldsmith, C. E. Gregory, Thomas M. Grier, D E Goe, Mrs. Moshier T. Greene, J. F. Kester, Ernest L Clark, Edward Stockwell, Wells Goodhue, C. E. Wilson, P. H. Hoover, H. S. Manning, W. C. McKinlock, W. H. McKinlock, Mrs. McKinlock, S. F. B Morse, J. A. Mosher, D H. Ogden, Miss Ogden, J. B. O'Hara, Chas. T. Page, E. L. Powers, D. P. Perry, F. L. Perry, G. L. Reimann, J. Scribner, E. F. Seixas, Geo. S. Searing, A. M. Searles, H. Small, Thos. S. Stacey, M. J. Sullivan, B. E. Sunny, J. H. Shay, F. S. Terry, T. Theberath, C. H. Wilson, Chas. E. Wirt, John Valentine, A. W. Harvey, M. M. Wood, H. I. Hadaway, James M. Kearney, C. H. Wilmerding.

Cincinnati.—P. A. Clisdell, George B. Edgar, C. E. Jones, Robb Mackie, R. J. Randolph, Chas. J. Foust, T. J. Ryan, R. S. Stearnes, John Turner, J. W. Wilshire.

Cleveland, O.—W. B. Cleveland, F. A. Lane, Fred A. Scheffler, L. B. Le Vake.

Cuyahoga Falls, O.—C. A. Babcock, R. S. Willard, E. L. Babcock, Mrs. Willard.

Colorado Springs, Col.—E. E. Wade.

Columbia, Mo.—William Shrader, M. L. Lipscomb.

Cedar Rapids, Ia.—W. J. Greene.

Davenport, Ia.—C. W. Grant, Mrs. Grant, G. E. McFarland.

Dayton, O.—W. H. Ashton.

Dallas, Tex.—D. M. Clower,

DeSoto, Mo.—J. D. Barth.

Denver, Col.—S. S. Campbell, Thomas H. Smith, P. H. Sterling, E. W. Rollins,

Des Moines, Ia.—C. K. Mead, Mrs. Mead, J. A. Colby.

Eau Claire, Wis—Frank S. Culver.

Evansville, Ind.—C. P. White.

Fayette, Mo.—A. P. Warren, T. Perry Smith.

Fort Wayne, Ind.—Chas. S. Bradley, C. S. Knight, W. C. Knight, James J. Wood.

Galesburg, Ill.—Edwin J. Larkin.

Hartford, Conn.—E. B. Hatch, C. E. Newton.

Houghton, Mich.—J. R. Dee.

Indianapolis, Ind.—A. D. Adams, C. D. Jenney, George C. Pyle.

Jacksonville, Ill.—M. P. Ayers, T. M. Doan.

Jackson, Mich.—W. A. Foote.

Janesville, Wis.—P. Norcross, Mrs. Norcross.

Jonesboro, Ind.—C. J. Butler.

Kenosha, Wis.—T. S. Boardman.

Kansas City, Mo.—Leo H. Gamp, A. M. Miller, G E. Claflin, Thomas F. Clohosey, W. T. Osborn, Geo. M. Myers and wife, G. A. Ross.

Kirksville, Mo.—J. B. Bragg.

Lockport, N. Y.—R. S. Bishop.

Louisville, Ky.—Campbell Scott.

London, Eng.—Prof. George Forbes, Vivian Hawkes.

Memphis, Tenn.—W. W. Carnes, Mr. Boardman.

Milwaukee, Wis.—S. G. Coleman.

Minneapolis, Minn.—Edwin S. Tice,

Montreal, Canada.—Albert J. Corroveau.

New Brunswick, N. J.—A. J. Jones,

New Britain, Conn.—L. C. Whitney.

New Orleans, La.—William Oswald, C. H. McFall

Nelsonville, O.—M. Poston.

Norwich, Conn.—George J. Jackson.

New York.—H. C. Adams, E. P. Atkinson, P. C. Ackerman C. O. Baker, Jr., A. H. Bauer, Louis Cassier, Mrs. Cassier, R. B. Corey, F. R. Colvin, B. E. Greene, H. M. Haines, W. J. Hammer, E. B. Hatch, M. M. Hayden, A. Mitchell Hall, Henry G. Issertel, George J. Jackson, W. J. Johnston, W. S. Key, J. C. Knight, A. B. Laurence, E. W. Little, Romaine Mace, Geo. T. Manson, Mrs. Manson, John J. Moore, F. A. Magee, J. D. Miller, P. W. Mitchell, T. C. Martin, H. C. Myers, J. P. McQuaide, Augustus Noll, W. F. Osborne, Nelson W. Perry, Geo. F. Porter, C. W. Price, H. T. Richards, John A. Seely, E. W. Seymour, C. D. Shain, C. E. Stump, H. J. Smith, H. M. Swetland, J. B Taltavall, Nikola Tesla, Herbert Laws Webb, B. R. Western, Fremont Wilson, E. E. Wood, W. T. Hunt, C. P. Mackie, J. C. Pierrez.

Newark, N. J.—R. O. Heinrichs, Wilson S. Howell, C. McIntire, Edward Weston.

Omaha, Neb.—M. J. Cowgill, F. J. Pearson,

Peru, Ind.—J. Horr.

Philadelphia.—C. A. Bragg, Miss Cumings, H. B. Cutter, A. J. DeCamp Mrs. DeCamp, Miss DeCamp, W S. Horry, H T. Paiste, A. H. Manwaring. Mrs. Manwaring, A. J. Martin, John K. Martin, James A. Pentz, T. Carpenter, Smith, E. Ward Wilkins,

Pittsburgh, Pa.—H. H. McDuffie, Alex. Jay Wurts, J. S. Crider, E. H. Heinrich, E. E. Little, G. H. Blaxter, L. B. Stillwell, F. Moore, H. McGonnigle, J. W. Marsh.

Pittsfield, Mass.—Henry Hine, John Hoover, A. Taylor, Calvert Townley

Racine, Wis.—P. H. Korst.

Ravenna, O.—C. L. Rodman.

Rensselaer, Ind.—W. B. Austin, Mrs. Austin.

Roodhouse, Ill.—E. H. Higbee, Jr.

Rolla, Mo.—A. L. McRae.

Rutland, Vt.—M. J. Francisco, Mrs. Francisco.

Rochester, N. Y.—G. A. Redman and wife, C. R. Barney, Mrs. J. N Quine.

Rockford, Ill.—M. A. Beal, Wm. E. Hinchliff, George Mayo, W. B. Roberts.

St. Louis.—Dr. Wellington Adams, T. N. Ambler, James I. Ayer, P. C. Burns, S. G. Booker, F A. Churchill, Jr., A. W. Dutton, H. Elliott, Jr., J. A, Ferguson, W. L Flower, J. F Gerleman, J. H. Hopkins, W. N. Matthews. Louis Nahm, Prof. Nipher, A. Partridge, P. N Rose, F. Schlosser, R. V. Scudder, George C. Stedman, A. C. Thompson, C. G. Woods, Capt. J. A. J. Shultz, C. H. Talmage, G. F. Durant, E. Ruebel.

Syracuse, N. Y.—W. J. Morrison, H. J. Goercke, E. T. Pardee.

Salem, O.—D. L. Davis,

Seattle, Wash—Dr. E. C. Kilbourne.

Sewickley, Pa.—E. P. Young.

St. Joseph, Mich.—W. Worth Bean.

Steubenville, O.—J. G. Gwynne, Thomas Johnson.

Stevens Point, Wis.—H. C. Craig.

St. Joseph, Mo.—J. F. Dyer, J. H. Parker.

St. Paul, Minn.—John A. Berkley.

Springfield, Ohio.—J. H. Miller,

Springfield, Mo.—Frank B. Smith.

Taylorville, Ill.—J. N. C. Shumway.

Telluride, Col.—P. N. Nunn.

Toledo, O.—John J. Moore.

Toronto, Ont.—J. H. Quinlan, Frederic Nichols.

Troy, N. Y.—E. G. Bernard.

Vandalia, Ill.—D. M. Clark, Anna M. Clark.

Vincennes, Ind.—H. W. Frund.

Washington, D. C.—F. W. Royce,

Washington Court House, O.—Jerome Penn.

Washington, Mo.—A. A. Tibbe.

Warren, O.—W. D. Packard.

Waterbury, Conn.—J. O. Crane.

Worcester, Mass.—H. H. Fairbanks.

Windsor, Conn.—M. E. Baird, A. D. Newton.

West Superior, Wis. A. A. Cross.

CONVENTION NOTES.

The Ladies attending the Convention were most charmingly entertained by the committee of St. Louis ladies. Not a moment was left open, but a continued round of pleasure was furnished. Receptions, theatre parties, carriage drives, which the beautiful weather fortunately permitted, etc., etc., were enjoyed. A ladies' luncheon was also given at the rooms of the Electric Club, in fact nothing that could be imagined to add to their pleasure was left undone. The ladies attending the convention were Mrs. J. Turner, Cincinnati; Mrs. C. J. Foust, Cincinnati; Miss A. E. Fortiner, Chicago; Mrs. A. H. Manwaring, Philadelphia; Mrs. Geo. T. Manson, Brooklyn; Mrs. L. A. Beebe, Hutchinson, Kan.; Mrs. G. A. Redman, Rochester; Mrs. J. H. Quine, Rochester; Mrs. G. N. Meyers, Kansas City; Mrs. A. J. DeCamp, Philadelphia; Miss DeCamp, Philadelphia; Miss Clara M. Cumings, Philadelphia; Mrs. W. E. Hinchliff, Rockford; Mrs. M. A. Beal, Rockford; Mrs. D. H. Ogden, Chicago; Mrs. M. A. Burleigh, Camden, N. J.; Mrs. J. J. Burleigh, Camden, N. J.; Miss E. W. Armstrong, Camden, N. J.; Miss C. W. Morgan, Camden, N. J.; Mrs. M. J. Francisco, Rutland, Vt.; Mrs. L. Cassier, Brooklyn; Mrs. C. W. Grant, Davenport, Iowa; Mrs. W. B. Austin, Rensselaer, Ind.; Mrs. W. H. McKinlock of Chicago accompanied by Mrs. Moshier T. Greene. The ladies' committee of reception were Mrs. J. I. Ayer, (who gave the ladies a most charming reception at her residence), Mrs. W. L. B. G. Allen, Mrs. T. N. Ambler, Mrs. Robt. McCullough, Mrs. John Segrist, Jr., Mrs. Geo. A. Rowley and Miss Rowley, Mrs. Henry O'Neil, Mrs. E. J. Bagnoll, the Misses Shultz, Miss Bantos.

The Convention Special Trains were great successes this year. The "Electrical Special" from New York left at noon on Sunday and picking up delegates all along its route, reached St. Louis at 7 p. m. on Monday, with about 100 passengers on board—the train being greeted 65 miles out by a reception committee detailed for the purpose. Thanks to the care and skill of Mr. C. O. Baker, Jr., Master of Transportation, and Mr. Haines, of the Pennsylvania Railroad Co., everything had been thought of and provided necessary to make the trip a success, and success it was. As much may be said of the Chicago Special, which left Chicago on Monday night, under the direction of Messrs. A. Scribner and F. S. Bishop, and which landed a party about 60 strong, on Tuesday morning. At East St. Louis the party were met by a reception committee with carriages, and landed at the hotel.

The Headquarters of the Association were temporarily established in one of the parlors of the Southern Hotel, but it was soon found convenient and desirable to remove them for permanent work to the new Bell Telephone Building, where Secretary Porter had his office going all the time, with the constant assistance of several members of the executive committee. The work of the Association has rarely excited so much attention in the city visited as it did in St. Louis, and hence the inquiries and requests for information were simply innumerable. The lecture by Mr. Tesla also threw a vast amount of extra work on the Secretary's office, owing to the extraordinary demand and pressure for tickets. But the office was never more efficiently conducted, and its management reflected great credit on Mr. Porter and his assistant Miss Billings.

The Meetings of the Association were held in what will ultimately be the operating "central" of the new Telephone Exchange Building, corner of Tenth and Olive streets. In spite of the distance from the hotel—at least half a mile—the sessions were very well attended. The hall was very handsomely decorated with red, white and blue festoons, crossed with orange. At the back of the stage were the stars and stripes, and over it were some very fine electroliers. Above the flag was an inscription: "Electricity; The Most Potent Force;" on the east wall was the word "Welcome," and on the west wall was the Missouri coat-of-arms. The effect was charming. As might be expected of Mr. George F. Durant, of the Telephone Company, everything possible was done to promote the comfort of the Association.

Mr. C. O. Baker, Jr., who has so often and so efficiently acted as Master of Transportation, was the recipient on Wednesday afternoon, in the ladies' parlor, of a beautiful silver punchbowl presented by the passengers on the Electrical Special from New York to St. Louis. The presentation took place about 5.30. The bowl was tendered to Mr. Baker in the name of the donors by Mr. T. C. Martin, who also read the address subsequently engrossed. Mr. Baker though rather taken by surprise, replied in a few neat and modest sentences and then the large party adjourned to an adjoining parlor to christen the bowl with champagne. A chased inscription around the rim of the bowl gave the story of its presentation.

The Electrical Club of St. Louis did itself proud. Its hospitality was of the most generous nature, and was without any congnizance of hours and seasons. The club has richly appointed rooms in the Equitable Building, and these were decorated for the occasion. A luncheon was on service all the time. The members and officers of the Club were in constant attendance, and were unremitting in their attentions to visitors. The Club was, in fact, the centre of the convention activities of the week.

Central Stations were the main objects of interest on Tuesday evening, and in a procession of about 40 carriages, the members left the Electric Club, at 8 o'clock, and were escorted to the Missouri Electric Light and Power Station, the Municipal Light and Power Station, and the Union Depot Railway power house. The trip was exeedingly enjoyable, and many points of value and interest were elicited.

Secretary George F. Porter was made very happy and rendered positively speechless before the close of the convention by the presentation of a beautiful gold watch. Mr. Porter has a most disagreeable habit of always wanting to have things ready two or three days in advance, and it was thought that this gift might bring him to time; instead of which it knocked him out.

TELEPHONIC TRANSMISSION OF MUSIC BETWEEN NEW YORK AND CHICAGO.

The possibilities which the future holds out for the transmission of music to long distances by means of the telephone are not being lost sight of, and a most interesting test designed to show the capacity of the Chicago-New York Telephone Line for this purpose was recently undertaken by the Long Distance Telephone Company. In order to obtain a competent judgment as to the quality of transmission, arrangements were made with Mr. Theodore Thomas, the well-known musical director, of Chicago, to listen at that end of the line.

On the afternoon of February 27th a number of musical critics gathered at the New York office of the Long Distance Company, No. 18 Cortlandt street, where a Steinway Grand piano was placed, the sound waves being led to the long distance transmitter by a large funnel. Miss Minnie Wetzler, piano soloist of the Boston Symphony Orchestra, played a number of selections, and Mr. Plunket Greene, the basso, sang a number of songs. Mr. Thomas expressed himself as more than pleased with the results of the test, and went even so far as to say that the results obtained over the Chicago line were better than those which he had heard on previous occasions in the East over very much shorter lines.

There can be little doubt that, if properly exploited, long distance concerts can be made a commercial success, which may add not a little to the revenue of the Long Distance Company.

THE SOUTH LONDON ELECTRIC RAILWAY.

In a recent paper read before the London Society of Civil Engineers, Dr. E. Hopkinson gave a number of most interesting figures on the operation of the South London underground electric railway. The engines average 230 indicated horse power each, or only one-half of full load; and they consumed 27¼ pounds of steam per indicated h. p. hour, as compared with 22 pounds at half load, obtained with Willans high-speed engines. The combined efficiency of engine and dynamo is 78 per cent. at full, 70 per cent. at half load, and 65 per cent. at quarter load. They consume 8.04 pounds of North Country coal per Board of Trade unit. With average load the loss in long feeders is 5.7 per cent., and in distributors 3.5 per cent., a total of 9.2 per cent., say 10 per cent., equal to 1¼ tons of coal per day, which exactly comes to the interest on £7,000—the actual cost of conductors. The coal burnt is 35 to 40 tons a day. The electrical efficiency of the system over all is 62 per cent., and the average efficiency of of locomotive 70 per cent. The total cost of running is 5.1d. per train mile without wages, as against 6.3d., the total guaranteed cost, or less by 20 per cent. than the guarantee, and this though the trains are 30 per cent. heavier. In additional tables the details of cost to December 31, 1892, were given: Train mileage, 214,417; number of passengers, 3,317,602. Cost of generator station working, including renewals and repairs: wages, 1.12d.; fuel, 2.42d.; water and gas, 0.28d.; oil and stores, 0.41d.; repairs, 0.36d.; a total of 4.59d. per train mile, or equal to 1.56d. per Board of Trade unit. The cost of locomotive working, including repairs, was: generating station, as above, 4.59d.; wages, 1.98d.; oil and stores, 0.10d.; repairs, 0.23d.; total, 6.90d. per train mile. The figure 1.56d. per B. T. unit will interest central-station engineers, as it is the lowest of any generating station, save Bradford, which generates at 1.41d. per trade unit, but using cheaper coal; at Pall-Mall the cost is 2.26d. Dr. Hopkinson justifies the use of jockey pulleys, mathematically showing that, when the speed of displacement traveling by wave motion forward is exactly equal to the speed of belt, there is very little loss by friction; and this condition is secured with a link belt running at 3,500 feet per minute, with a tension of 1,600 pounds, and weighing eight pounds per lineal foot. As to use of locomotive, the weight is four tons of frame and six tons of motor; the motors, if separate, would have to be heavier in total, and the car frames would have to be made heavier—there might be a saving of two tons, 1 per cent. or 2 per cent., an advantage, thought Dr. Hopkinson, greatly outweighed by having the motors on one vehicle.

CUTLER & HAMMER.

Chicago is to have a new factory for high grade electric specialty and repair work. Cutler & Hammer is the name of the new firm, both of whose members are well and favorably known to the electrical trade in the west.

Mr. H. H. Cutler has had an experience of over eight years in central station work and may perhaps be better known to the trade as the inventor of the Cutler hot wire measuring instruments. Mr. E. W. Hammer has had a wide experience in all branches of high-class electrical manufacturing and has been for sometime general manager of the Chicago Electrical Manufacturing Company.

The new firm will make a specialty of all kinds of electrical testing and calibrating. They have a storage battery capacity of 1,000 amperes and 300 volts, as well as a most complete set of standard testing instruments. The factory is already well equipped for this kind of work. The officers of the new firm are at 313 Canal street, Chicago.

THE FIRST TELEPHONE "GUN."

The Shaver Corporation, of No. 1 Broadway, announces that it and its thirty or more sub-companies are preparing to enter the Electrical Telephone field promptly after March 7th. The sub-companies at McKeesport, Pa., have completed their exchange of about 100 subscribers and will open for business March 8th. This exchange is fitted with the Shaver duplex magneto telephones and the Utica Fire Alarm Telegraph Co.'s magnetos, switches and central office apparatus, thus claiming to avoid all the detail patents of the Bell Co. for exchange apparatus. The Shaver Corporation has a capital of $2,000,000, and some 50 prominent stockholders. The officers of the company are: President, Wm. H. Curtiss, private secretary of Wm. Rockefeller; Treasurer, Henry S. Iselin of the well-known family of bankers; Vice President and General Manager, George F. Shaver; Secretary, A. Emerson Shaver. This company seems determined to inaugurate a lively competition with the Bell Co. The Shaver Corporation offer protection to their sub-companies against litigation by bond.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XV. MARCH 15, 1893. No. 254.

NOTES ON LIGHTNING PROTECTION.

BY

Alexander Jay Wurts.

CENTRAL station men have not, as a rule, any very clear or correct ideas regarding the problem of lightning protection. A certain make of lightning arrester is purchased, one terminal of which is connected to the line, the other to the ground; then, if an armature or converter is damaged by a discharge the arrester is at once condemned. As a matter of fact, however, the party who installs the arrester is more often to blame in not following closely the instructions sent with the apparatus.

Lightning arresters as they are now constructed usually consist of a simple spark gap, in connection with some form of automatic circuit-interrupting device. As a circuit interrupter the apparatus can be easily tested by connecting the arrester across the terminals of a generator and in series with a switch; then, by bridging the spark-gap with a crumb of tin foil and throwing the switch a short circuit will be established, which if satisfactorily interrupted and if the test can be indefinitely repeated, well and good, but if not, the arrester, as an automatic device, can be properly rejected. However, the circuit interrupter is in a sense little more than a labor saving device and does not bear directly on the efficiency of the apparatus as a lightning protector. The feature of a lightning arrester pure and simple is the spark-gap, and this should provide a path to earth for the discharge, which shall offer less resistance to its passage than the insulation in any part of the system. It is desirable therefore that the spark gap be small; in other words, that it shall break down with an electric strain considerably less than the breaking-down E. M. F. of the armature or converter insulation. But even with a very small spark-gap an arrester may often fail to take the discharge. There are several reasons for this, which we will now consider under the following heads:

1. The leads to and from the arrester. 2. The ground connection. 3. Nodal points.

Leads to and from the Arrester.—It is well known that discharges, such as occur across the spark-gap of an arrester, are oscillatory in character; that is, they have the properties of an alternating current of very high frequency and consequently meet an enormous resistance when forced to pass through a coil of wire. For example, discharges of this kind will often jump two or three inches of air space rather than pass through only a few turns of large copper wire. Even long, straight wires offer considerable resistance to these discharges, so that if the leads to or from a lightning arrester are long or crooked, or both, the resistance of the spark-gap forms but a small fraction of the total resistance included in the discharge circuit.

Lightning arrester connections are commonly made with odd lengths of wire lying about the station, and if a little too long (it is perhaps a pity to cut them) the extra length is neatly coiled around a broom handle or convenient gas pipe, and thus unwittingly an enormous resistance is connected in series with the arrester. The writer has repeatedly noticed just such coils in lightning arrester connections, and on asking for an explanation it was usually suggested that they make a rather neat appearance. Frequently these wires are given a turn or two around porcelain insulators and sharp turns are made according to the fancy of the wireman. Not infrequently the ground wire will be led some considerable distance outside and away from the station to a water pipe, well, or stream of water, the object being excellent, but the method poor.

The spark-gap arrester works to advantage only when intelligently installed. When possible the line to be protected should be led down and close to that which is to form the ground plate of the arrester; in other words, the charge should be forcibly led as near to the ground plate as possible before being discharged into the discharge circuit. If this plan were followed out the leads to and from the arrester could not be other than short and straight. No. 4 wire will be found sufficiently large for all lightning arrester connections. The joints should be carefully soldered.

Ground Connection:—It will hardly be necessary to mention that a good ground is one of the essentials of efficient lightning protection. In ordinary cases common sense will indicate the proper course to pursue, but out on the line the best results are not always easily obtained. In one instance, familiar to the writer, the ground wires from several line arresters were simply pushed down into the earth, and after several converters had been punctured the arresters were condemned as offering no protection whatever.

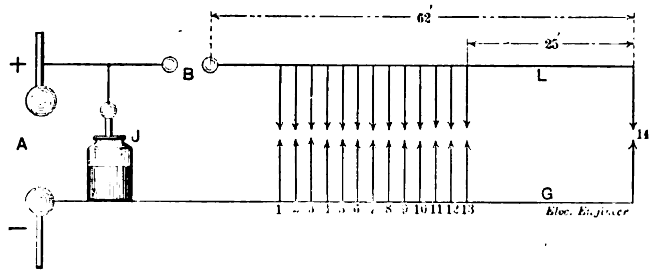
In central stations the best and usually most convenient ground is the water main. If this be not close at hand the line to be protected should be run as near to it as possible and then careful connections should be made from the arrester to this main. It may often be convenient to run a branch water pipe direct to the ground terminal of the arrester.

If this method is not practicable a deep hole should be sunk directly under the arrester and a copper plate having an area of not less than 50 square feet, buried in it. The ground terminal of the arrester should be soldered to this plate and the hole filled in solidly with fine coke. The thickness of the plate is not important as far as ground connection is concerned, but it should be thick enough to be lasting, say, $\frac{1}{8}$ of an inch. The depth of the hole should be such as to insure permanent dampness.

For line arresters even the above method will not always be convenient. The following, however, is considered an excellent substitute: Dig a hole directly under the arrester about two feet in diameter and deep enough to reach damp earth. From this point down drive 6 or 8 feet of (pointed) gas pipe, in the upper end of which screw a solid brass plug, and to this plug solder the ground wire of the arrester. In this case the lower portion of the ground wire should consist of about 100 feet of bare wire formed into a loose coil, the convolutions of which should be evenly distributed throughout the depth of the hole and the latter then filled in solidly with fine coke. In this manner advantage is taken of the deep, damp earth and surface drainage as well. In some instances it may be desirable to conceal or protect the ground wire between the arrester and earth. For this purpose an ordinary gas pipe will offer a good protection and at the same time serve to decrease the resistance of the discharge circuit even though the pipe be thoroughly insulated from the wire.

Nodal Points:—It is now well known that disruptive discharges form nodal or neutral points along the line and that at these points there will be little or no tendency to discharge. If a single arrester be connected to the line it may, or may not, discharge, according to circumstances ; a certain discharge may take place across the arrester, or it may pierce the insulation of an armature, or it may even do both at the same time. In fact these nodal points are not fixed but are constantly changing their positions. This part of our subject can be better illustrated by referring to the accompanying diagram, Fig. 1.

Let A represent the terminals of an influence machine ; J a powerful battery of Leyden jars ; B a large spark-gap; L is a wire which may represent a trolley line ; G a second wire which may represent the ground ; 1, 2, 3, etc., up to 13 are $\frac{5}{32}$-inch spark-gaps placed 12 inches apart and connected between wires L and G. These may represent as many lightning arresters connected to the line. The connections and distances are all clearly indicated. If now the influence machine A be set in motion the battery J will become heavily charged, till finally a violent disruptive discharge will occur at B, and thus suddenly charge the line L with a different potential from line G, so that there will now be a tendency for a disruptive discharge to take place between lines L and G, and in fact this discharge will pass at one or more of the spark-gaps 1, 2, 3, etc. These discharges occur in a great variety of ways, the following being a few examples : A single brilliant spark may pass at any one of the first ten gaps. Two, three and occasionally four simultaneous sparks, variously located, will pass between one and ten ; sometimes these occur at successive gaps, but they are more often scattered. In some instances the discharges are of equal brilliancy, in others one of two intense sparks would pass one or two gaps together with a much fainter discharge or scarcely perceptible spit at any of the other gaps included in the first ten. A discharge never occurs across any of the last three gaps. Four of the first 10 gaps are then increased to $\frac{10}{32}$ inch with the result that the discharge frequently selects one of these larger gaps in preference to any of the others. Occasionally, however, sparks will jump one of the larger gaps together with one or two of the smaller ones, and so an indefinite number of combinations can be produced with results emphatically demonstrating that with several spark-gaps there is no certainty that the discharge will take place across any particular one of them.



AN EXPERIMENT IN LIGHTNING PROTECTION.

A $\frac{5}{32}$-inch gap is now connected at 14 and with every discharge at any one of the first ten gaps a faint, threadlike spark will pass at 14. It can hardly be called a disruptive discharge and is not of a character likely to do damage. This minute spark is due to what Dr. Lodge calls the "recoil kick," that is, the electric waves strike the ends of the wire and recoil with increased intensity. When the gap at 14 is increased these threadlike sparks become less and less frequent, till finally when the gap equals $\frac{17}{32}$ inch they cease altogether. However, when only 1 and 14 are connected to the lines brilliant discharges frequently occur at either one or the other, or at both.

Now, assuming that the above conditions and results correspond in many respects to those found in actual practice, the lesson to be learned is a simple one : Electric light and power circuits should be provided with spark-gap lightning arresters at frequent intervals along the line. Two or three to the mile would seem to be sufficient in a majority of cases; in others a fewer number might suffice. A spark gap arrester should certainly be connected at either end of each line. An electric circuit well equipped with properly constructed line arresters should have little to fear from disruptive discharges.

Summary:—Follow the instructions sent with the arrester. Test the automatic circuit interrupting device. Make the leads short and straight. Make the ground connection of the very best, and avoid nodal points by using a large number of line arresters.

AN AMPERE FOOT TABLE.

BY

G. T. Evans.

THOUGH wiring tables in electrical literature are already as thick as pie recipes in New England cook books, and an addition to the number cannot altogether be a novelty if it may not seem superfluous, I still believe the table here appended has some points in its favor. It is the result of a need for a concise and comprehensive "bureau of information," adaptable to the majority of problems met with in estimating sizes, weights, etc., of wires in contracting and construction work.

In this table all determinations are made for "double" feet, so that in estimating weight and length of series, the distance from point of supply to point of distribution, and not the total length of circuit need be observed; as the table gives the maximum capacity in "ampere feet" for various losses in volts, it is not restricted to any particular E. M. F. or lamps, motors or any other transforming device. As is well known from the experiments of Dr. Matthiessen, the constant 21.4 is the area in circular mils of one double foot of commercially pure copper having a resistance of one ohm at a temperature of about 59° F. Such a wire with a fall of one volt along its length would be traversed by one ampere. To double this current, twice the fall in voltage would be necessary ; likewise to double the length of circuit and pressure, a flow of one ampere would require the same increase in volts, so that it is apparent that considering the factors of the unit "ampere foot" simply as numerics, they are equal in value, and 1,000 ampere feet, for instance, would cause the same voltage loss whether the feet = 1,000 and the amperes = 1, or vice versa, the same size of wire being used in each case.

Of course it is obvious that increased resistance due to heat caused by flow of current is not taken into account in the above, and in general examples it need not be. The only check necessary to excessive amperage on a wire is its safe carrying capacity. Two determinations of these limits are given in the table. One of these, for insulated wires encased in moulding, is from experiments made by Mr. A. E. Kennelly, and the other, for exposed insulated wires, is that adopted by the Board of Fire Underwriters of Alleghany Co., Pa.

The variations of volt losses in the table are sufficiently numerous for most work ; but they may be greatly increased, if desired. The "Maximum Ampere Feet" for a loss of one volt on a certain sized wire will become that for a loss of .1 volt by inserting a decimal point, or that for 100 volts by adding two ciphers. In fact the maximum ampere feet for any loss on any sized wire may be found by

Maximum Ampere Feet.

An Ampere-Foot Table for Calculating Sizes, Weights, Etc., of Line Wires.—Compiled by G. T. Evans.

multiplying the "Maximum ampere feet" for loss of one volt for same sized wire by number of volts to be lost.

The part of the table giving weights per double foot of some of the insulated wires sold by the pound will be convenient. These have been computed from figures furnished by the several companies and are thought to be approximately correct. An allowance for waste and sag should always, of course, be made. This evidently will vary with the distance and variety of work to be done.

A few examples will illustrate how the table may be used:

(1.) A contractor wishes to carry current for 100 lamps, each lamp taking one ampere, a distance of 100 feet, using wire concealed in moulding. Ten volts is the limit of loss. Can he do it?

One hundred lamps each taking 1 (ampere) × 100 (feet) = 10,000 (ampere feet). With a loss of 10 volts a wire between the sizes Nos. 7 and 6 could be used; but the safe carrying capacity of the larger of these wires is but 36 amperes, so it is evident that 100 amperes could not be transmitted with 10 volts loss and be safe.

(2.) An engineer while inspecting a plant finds a line of No. 6 wire 1,000 feet long supplying 10—1 ampere lamps. He wishes to know the loss. 10 × 100 = 10,000 (ampere feet). Following down the column for No. 6 wire, 10,426 ampere feet is found, which is the maximum ampere feet for a drop of 8.5 volts.

(3.) A line is to be run from an electric station to feed a 200-light transformer 10,000 feet distant. The drop on line is not to exceed 100 volts; the ratio of transformation is one to 40; the lamps require ½ ampere each. What size wire is to be used, supposing the transformer is without loss? We have:

Total amperes on primary line =

$\frac{100}{40} = \frac{5}{2}$; $\frac{5}{2} \times 10{,}000 = 25{,}000$ ampere feet. A wire between the sizes Nos. 13 and 12 will answer the purpose, or practically, a No. 12 wire.

(4.) If the wire in the above was specified "K K" what would be the weight, making no allowance for sag?

Weight of 1 double foot = .062 lb.; 10,000 × .062 = 620 pounds.

5. There is a motor which is designed to have a pressure of 500 volts at its brushes. It is 2,000 feet from supply; it is of 20 h. p. and its efficiency is 80 per cent; a loss of 50 volts is allowed. What size wire is needed?

$$\text{Ampere feet} = \frac{\text{horse-power} \times 746 \times \text{distance}}{\text{volts} \times \text{efficiency}} =$$
